14.1.1 The name or brand of the manufacturer, the name of the material or UNS number, the letters ASTM, the product specification number, heat number, class (if applicable) and nominal size shall be legibly marked on each piece ¾ in. (19.0 mm) outside diameter and larger and lengths greater than 3 ft (914 mm). The material marking shall be by any method that will not result in harmful contamination.

14.1.2 For material smaller than ¾ in. (19.0 mm) outside diameter, or lengths under 3 ft (914 mm), the information specified in 14.1.1 shall be legibly marked on each piece or marked, at the option of the manufacturer, on a tag securely attached to the bundle or box in which the material is shipped.

15. Packaging and Package Marking

15.1 The following information shall be marked on the material or included on the package, or on a label or tag attached thereto: name of the material or UNS number, heat number, condition (temper), the letters ASTM, the product specification number, the nominal pipe size, gross, tare, and net weight, consignor and consignee addresses, contract or order number, and such other information as may be defined by the purchase contract.

16. Keywords

16.1 cold worked; hot finished; nickel; nickel alloys; seamless pipe; seamless tube

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: D 380 – 94 (Reapproved 2000)

Standard Test Methods for Rubber Hose[1]

This standard is issued under the fixed designation D 380; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. These methods have been approved for use by agencies of the Department of Defense to replace Methods 7431, 7421, 10011, 10021, 10211, 10221, 10311, 10341, 10351, and 10361 of Federal Test Method Standard No. 601 and for listing in the DoD Index of Specifications and Standards.

1. Scope

1.1 These test methods describe procedures for inspection and test of all types and constructions of rubber hose.[2]

1.2 In case of conflict between provisions of these test methods and those of detailed specifications or test methods for a particular hose, the latter shall take precedence.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. General Test Methods

3.1 Except as otherwise specified in these test methods for rubber hose, the following test methods, applicable in general to vulcanized rubber, shall be complied with as required and are hereby made a part of these test methods:

3.1.1 *General Physical Test Requirements*—Practice D 3183.

3.1.2 *Tension Test*— Test Method D 412.

3.1.3 *Aging Test*—Test Method D 572, Test Method D 573, and Test Method D 865.

3.1.4 *Adhesion Test*— Test Methods D 413.

3.1.5 *Immersion Test*— Test Method D 471.

3.1.6 *Hardness Test*— Test Method D 2240.

3.1.7 *Hardness Test*— Test Method D 1415.

4. Significance and Use

4.1 These test methods provide uniform methods for inspection and test of rubber hoses that can be referenced in hose specifications for various applications.

4.2 Uniform test methods make quality comparisons of hose easier and more meaningful, and are more economical particularly when the same rubber vulcanizates are used in different

[1] These test methods are under the jurisdiction of ASTM Committee D11 on Rubber and are the direct responsibility of Subcommittee D11.31 on Rubber Hose.

Current edition approved Nov. 15, 1994. Published March 1995. Originally published as D 380 – 33. Last previous edition D 380 – 87.

types, constructions, or sizes of hose.

5. Sampling

5.1 A sample of sufficient length for proper performance of the required tests shall be cut from the hose when possible without impairing its use and the pieces of hose from which samples have thus been cut shall be accepted by the purchaser as full length, provided the hose meets the specified requirements. The length of samples required depends on the tests which are required. The following will show the minimum length required for the various tests:

5.1.1 *Thickness of Tube, Cover, and Rubber Elements; Tensile Strength and Elongation (Original); Adhesion*:

Nominal Bore Diameter, mm (in.)	Sample Length, mm (in.)
below 19 (0.75)	900 (36)
19 to 31.5 (0.75 to 1.25)	750 (30)
over 31.5 (1.25)	600 (24)

5.1.2 *Volumetric Expansion*—For all sizes 450 mm (18 in.)

5.1.3 *Straight Burst*— For hose nominal 76 mm (3 in.) and smaller, 450 mm (18 in.); for hose over 76 mm in inside diameter 600 mm (24 in.) but not exceeding 900 mm (36 in.). Use 900 mm for all sizes of jacketed rubberlined fire hose.

NOTE 1—Volumetric samples can be used for burst tests when hose is nominal 76 mm (3 in.) inside diameter and smaller.

5.1.4 *Curved Burst*— For all bore diameters of hose, 900 mm (36 in.).

5.1.5 *Hold Test*—For hose 76 mm (3 in.) and smaller, 450 mm (18 in.); for hose over 76 mm in inside diameter, 600 mm (24 in.) but not exceeding 900 mm.

5.1.6 *Immersion Test—Volume Change and Strength Deterioration*:

Nominal Bore Diameter, mm (in.)	Sample Length, mm (in.)
below 19 (0.75)	450 (18)
19 to 31.5 (0.75 to 1.25)	300 (12)
over 31.5 (1.25)	150 (6)

5.1.7 *Low-Temperature Test*:

Nominal Bore Diameter, mm (in.)	Sample Length, mm (in.)
below 31.5 (1.25)	500 (20)
31.5 to 50 (1.25 to 2)	700 (28)
over 50 (2)	1 000 (40)

5.2 Where the construction of the hose does not permit the cutting of samples as described in 5.1 without impairment of use, as in wire inserted hose, dredging sleeves, etc., a separate length having the same specifications shall be provided, either as an additional length or as a prolongation built onto the hose. Wire shall be omitted from the prolongation or sample length unless the detailed physical tests include requirements that measure the effect of the wire or metal elements in the construction. Additional length taken for purpose of tests shall be paid for by the purchaser, provided they conform to the specified requirements.

5.3 The sampling of woven-jacketed rubber-lined hose shall be in accordance with detailed specifications for this material.

6. Measurement of Hose

6.1 *Length*—Determine the length by means of a steel tape or calibrated measuring device. It shall not include the length of fittings except when specifically so requested and recorded. In the case of woven-jacketed rubber-lined hose, or hose with a helical wire reinforcement, determine the length under a 70-kPa (10-psi) internal pressure.

6.2 *Outside Diameter and Reinforcement Diameter*— Measure the circumference with a flexible tape and determine the diameter by calculation. Use of a pi (π) tape graduated to read the diameter directly is acceptable. On diameters of 25 mm (1 in.) or less, caliper measurements are acceptable when at least two measurements are made approximately 90° apart and the measurements averaged. The measuring device shall be capable of measuring in increments of 0.25 mm (0.01 in.) or less. All diameter measurements shall be made at least 25 mm (1 in.) distance back from the ends of the hose.

6.3 *Inside Diameter*— On hose up to and including nominal inside diameter of 75 mm (3 in.) suitable expanding ball gages, telescoping gages, or cylindrical-plug gages shall be used.

6.3.1 The measuring devices shall have the following minimum precision:

Nominal Bore Diameter, mm (in.)	Plug Gages, mm (in.)	Calipers, mm (in.)	Scales, mm (in.)
25 (1) or less	0.25 (0.01)		
over 25 to 50 (1 to 2)	0.50 (0.02)		
over 50 to 75 (2 to 3)	0.75 (0.03)		
over 75 (3)		0.25 (0.01)	
150 (6) or more		0.50 (0.02)	0.50 (0.02)

6.3.1.1 Plug gates shall have the maximum increments in diameter as given above and a minimum step length of 9.5 mm (0.37 in.).

6.3.1.2 Ball gages and telescopic gages shall be capable of measuring increments of 0.50 mm (0.02 in.) or less.

6.3.2 On hose 150 mm (6 in.) or larger in nominal inside diameter, in addition to inside calipers, a graduated steel scale can be used. On hose 150 mm (6 in.) or larger the measuring device shall be capable of measuring 0.50 mm (0.02 in.) or less. With the exception of cylindrical plug gages, at least two measurements shall be made approximately 90° apart and these measurements averaged. For hose that has a visual inside diameter variation at the end of the hose, for example, the flared or necked down end on wire braid reinforced hose, measurements shall be made at least 25 mm (1 in.) distance back from the end of the hose.

6.4 *Wall Thickness*— Determine the wall thickness at least 12 mm from the end of the hose to avoid flare. Use a micrometer with a rounded anvil in contact with the inside of the hose. Contact surface of the anvil should be about 8 mm long. Support for the anvil should be smaller in diameter than the anvil to avoid inward flare. Care is needed to be sure that the anvil and the foot are square to the surface of the hose. Sufficient force shall be applied to obtain firm contact with, but not indent, hose surface.

6.4.1 The minimum wall thickness shall be the minimum measurement obtained from a series of measurements taken around the circumference of the hose but concentrated in the area visually suspected of being thin.

6.4.2 The maximum wall thickness shall be the maximum measurement obtained from a series of measurements taken around the circumference of the hose but concentrated in the area visually suspected of being thick.

Copyright by the ASTM International
Wed Feb 02 01:45:26 2005

6.4.3 The average wall thickness shall be the average of at least four measurements taken equidistant around the circumference of the hose.

6.5 *Wall Concentricity*—The difference between the minimum and maximum wall thickness determined in 6.4.1 and 6.4.2.

7. Thickness of Tube, Cover or Other Rubber Elements

7.1 Determine the thickness of a rubber element from any type of hose in accordance with Method A of Practice D 3767.

7.2 Take the thickness of a rubber element adjoining a braid- or helical-wound reinforcing member of any material as the average between two measurements of thickness, one of which shall be obtained using the unbuffed specimen and the other using a specimen that is buffed just sufficiently to remove the braid or helical corrugations.

7.3 Take the thickness of a rubber element adjoining a seamless woven jacket of any material on a specimen that is buffed just sufficiently to remove the corrugations caused by the woven jacket. Where backing is used on a rubber element, remove the backing before measuring thickness.

7.4 Determine the thickness of a rubber element adjoining flexible metal convoluted lining at the valleys formed by the tops of the metal convolutions. Prepare the opposite side of the rubber element, adjacent to other reinforcing members, for thickness measurement as specified in the other paragraphs of this section, depending on the type of reinforcing member.

7.5 Determine the thickness of a rubber element adjoining reinforcing fabric woven prior to assembly in the hose on a specimen that is unbuffed.

8. Test Conditions

8.1 The temperature of the testing room shall be between 21 and 32°C (70 and 90°F). The samples to be tested shall be kept in this room for at least 30 min previous to the time of testing. In case of arbitration a test atmosphere of 50 ± 5 percent relative humidity at a temperature of 23 ± 2°C (73.4 ± 3.6°F) shall be used.

NOTE 2—These special test conditions shall be confined to tension and immersion testing only.

9. Number of Tests

9.1 When test value limits are established, test one specimen for each physical characteristic required in the detailed specifications for a particular hose, except in the immersion tests given in Sections 19-23 inclusive. If the results do not meet the specified requirements, prepare two additional specimens from the original sample and test. Should the results of either of these tests be below the specified requirements, consider the sample to have failed to meet the specifications.

9.2 If test value limits are not established, test at least three specimens and take the median.

10. Separation of Rubber Parts

10.1 Cut a sufficient length from the hose sample to provide longitudinal tension test specimens from hose 76 mm (3 in.) and under in nominal diameter and transverse test specimens on larger sizes. Separate the rubber parts to be tested from the balance of the hose. Perform the separation without the use of a solvent, if practicable, and without excessive stretching of the rubber. Make the separation a little at a time while the rubber is gripped near the point of separation. If it is necessary to use a solvent in the separating operation use commercial *iso*octane. If *iso*octane is used, place the rubber so as to permit free evaporation of the solvent from all parts of its surface, and allow it to rest at least 1 h before being tested.

TENSILE STRENGTH AND ELONGATION OF RUBBER

11. Procedure

11.1 Test in accordance with Test Method D 412. When specimen thickness is less than 1.5 mm (0.06 in.) after preparation a greater variation in test values can be anticipated. At times acceptable test specimens cannot be obtained or true values do not result from dumbbells prepared from the hose. In such cases substitution of sheet material in accordance with the section on Pieces of Practice D 3183 is recommended.

ADHESION TESTS

12. Test Specimens

12.1 From woven-jacketed rubber-lined hose, cut adhesion test specimens all transversely from the samples in rings 50 mm (2 in.) in width. Then open these rings and lay them out flat so as to give rectangular specimens of length equal to the full circumference of the hose. Accurately cut on each specimen a central strip of lining 38 mm (1.5 in.) in width, the cut extending through the lining but not entirely through the woven jacket. Separate these strips from the jacket at one end for a distance of about 38 mm.

12.2 From other types of hose, cut the adhesion test specimens transversely from the samples in rings 25 mm (1 in.) in width using a sharp tool that will leave clean edges. On hose 6.5 to 100 mm (0.25 to 4 in.), inclusive, in inside diameter test the specimens in ring form and refer to them as "ring specimens." For hose over 100 mm in inside diameter cut the rings through at the point where the outside ply of fabric ends, and open them to form strips that shall be referred to as "strip specimens."

12.3 Cut adhesion specimens from hose less than 6.5 mm in inside diameter longitudinally from the hose (Note 3). Since the width of these specimens will be less than 25 mm (1 in.), determine the adhesion on the contact width of the test specimen.

NOTE 3—Adhesion tests on hose smaller than 6.5 mm (0.25 in.) are not recommended, due to the size of the specimen available.

12.4 In hose constructions having braided wire reinforcing members, it is impractical to prepare adhesion test specimens.

12.5 On hose 19 mm (0.75 in.) to 100 mm (4 in.), inclusive, in inside diameter, having a woven wire filler reinforcement, prepare specimens for the adhesion test as follows: Cut the hose to form a longitudinal specimen 150 mm (6 in.) long and 50 mm (2 in.) wide. Flatten the specimen thus prepared and draw two parallel lines 25 mm (1 in.) apart along the tube and cover and cut through to the woven carcass. Separate from the jacket for a short distance the ends of the central portion between these two cuts. Determine adhesion in accordance

Copyright by the ASTM International
Wed Feb 02 01:45:27 2005

with 13.2 for strip specimens.

13. Procedure

13.1 *Ring Specimens*— Test in accordance with the Static-Mass Method or Machine Method of Test Method D 413.

13.2 *Strip Specimens*— Test in accordance with the Static-Mass Method or Machine Method of Test Method D 413.

13.3 For hose with woven wire reinforcement having an inside diameter under 19 mm (0.75 in.), the hose may be tested for value of tube adhesion by use of the ball-vacuum method as follows: Lay sections of hose in a straight line on an inclined table. Pass a steel ball, 3.18 mm (0.125 in.) less in diameter than the nominal inside diameter of the hose, through the hose while the internal pressure is 60 ± 10 kPa (18± 3 in. Hg) below the external pressure.

13.4 *Report*:

13.4.1 The report shall include the following:

13.4.1.1 Value of the adhesions obtained by the Static-Mass Method in accordance with 13.1 and 13.2 as average millimetres per second (or inches per minute) of separation under a stated mass required to separate specimens at an average rate of 0.42 mm/s (or 1 in./min),

13.4.1.2 Value of the adhesions obtained by the Machine Method (see the Calculation section of Test Method D 413) in accordance with 13.1 and 13.2, and

13.4.1.3 Value of adhesion obtained in accordance with 13.3, as ball passing or not passing.

13.5 *Precision and Bias*—The precision and bias of the Static-Mass and Machine Methods are given in Test Method D 413. No statement is made about either the precision or bias of the ball method for measuring adhesion of hose lining since the results merely indicate whether there is conformance to the criteria specified in the procedure.

PRESSURE TESTS

14. Types of Tests

14.1 Hydrostatic tests of hose consist of subjecting the specimen to the action of internal water pressure under specified conditions to determine either the bursting strength of the hose or the effect of lower hydrostatic pressures in producing changes similar to those occurring in service. In the latter case, the test may be used as an inspection proof test with a minimum safe limit. Bursting strength is determined on short specimens cut from the full hose lengths, but in tests for service effects and for proof inspection, the full lengths are used as specimens. The specimens may be tested, as required, in straight, curved, or kinked positions, depending upon the stresses which are desired to be evaluated.

14.2 Aerostatic pressure tests of hose consist of subjecting the specimen to the action of internal air or nitrogen gas pressure under specified conditions to determine the integrity and leak resistance of the hose or hose assembly. Normally the hose or hose assembly is submerged under water and a constant stream of bubbles is an indication of leakage.

15. Application of Pressure

15.1 Apply hydrostatic pressure by means of a hand- or power-driven hydraulic pump or an accumulator system. Connect the hose to the waterline or pump and fill with water prior to application of pressure, allowing all air in the hose to escape through a petcock provided for the purpose. This is important as a safety measure because expansion of air compressed in the hose, when suddenly released by bursting or other failure, might result in serious accident. Then close the petcock and apply the pressure at a uniform rate of increase of approximately 7 MPa (1000 psi)/min except for hose with bursting strength specified above 14 MPa (2000 psi), in which case the pressure shall be applied at a rate of 70 MPa (10 000 psi)/min or as rapidly as pump capacity will permit. Measure the pressure with a calibrated gage.

NOTE 4—The specified rate of 7 MPa (1000 psi)/min requires too much time for small-diameter high-strength hose, such as hydraulic brake hose, wire-reinforced grease gun hose, etc. With 3.2-mm (0.125-in.) hydraulic brake hose, pressure increases at rates as high as 280 MPa (40 000 psi)/min are satisfactory.

15.2 Apply aerostatic pressure by connecting the hose or hose assembly to a source of air or nitrogen gas pressure. Submerge the hose and couplings entirely in water such that visual observations of the hose assembly is permitted. Apply the specified internal pressure, measured with a calibrated gage, and maintain for the specified period of time. Any evidence of leakage from the hose or couplings shall be reported. Initial appearance of bubbles may be an indication of air entrapped in the hose wall. Agitate the hose after 2 min to break the air bubbles from the hose surface. Following this a steady stream of bubbles from any location shall be considered failure to meet the test.

16. Bursting Tests

16.1 *Straight Bursting Test*—The specimen for the hydrostatic test for bursting strength shall be at least 450 mm (18 in.) in length for hose 76 mm (3 in.) and smaller in inside diameter, and at least 600 mm (24 in.) in length for larger hose. Shorter or longer lengths may be burst tested when circumstances dictate, for example, when a burst on a manufactured part is specified. The pressure shall be raised as specified in Section 15, until failure, and the pressure at which failure occurs shall be considered the bursting strength of the hose.

16.2 *Curved Bursting Test*—The curved bursting strength test for woven rubber-lined fire hose shall be made in accordance with 16.1, except that the hose shall be firmly secured at both ends to a suitable test frame which is curved to a radius of 690 mm (27 in.).

16.3 *Precision and Bias*:

16.3.1 This precision and bias section has been prepared in accordance with Practice D 4483. Refer to Practice D 4483 for terminology and other statistical calculation details.

16.3.2 The precision results in this precision and bias section give an estimate of the precision of this test method with the rubber materials used in the particular inter-laboratory program is described below. The precision parameters should not be used for acceptance/rejection testing of any group of materials without documentation that they are applicable to those particular materials and the specific testing protocols that include this test method.

16.3.2.1 A Type 1 (inter-laboratory) precision was evaluated in 1989. Both repeatability and reproducibility are short-term;

Copyright by the ASTM International
Wed Feb 02 01:45:27 2005

a period of a few days separate replica to test results. A test result is the average value as specified by this method, obtained on two determinations or measurements of the property or parameter in question.

(1) Seven different types of hose were used in the inter-laboratory program. These were tested in varying numbers of laboratories as given in Table 1 on two different days.

(2) The results of the precision calculations for repeatability and reproducibility are given in Table 1 in ascending order of average hose burst pressure expressed in MPa.

(3) The precision of this test method may be expressed in the format of the following statements which use an appropriate value of *r, R* (*r*) or (*R*), to be used in decisions of test results. The appropriate value is that value of *r* or *R* associated with a mean value in the precision table closest to the main level under consideration at any given time, for any given hose in routine testing operations.

(4) Repeatability—The repeatability, *r*, of this test method has been established as the appropriate value tabulated in the precision table. Two single test results, obtained under normal test method procedures, that differ by more than this tabulated *r* (for any given level) must be considered as derived from different or non-identical sample populations.

(5) Reproducibility—The reproducibility, *R*, of this test method has been established as the appropriate value tabulated in the precision table. Two single test results obtained in two different laboratories, under normal test method procedures, that differ by more than the tabulated *R* (for any given level) must be considered to have come from different or non-identical sample populations.

(6) Repeatability and reproducibility expressed as a percentage of the mean level, (*r*) and (*R*), have equivalent application statements as above for *r* and *R*. For the (*r*) and (*R*) statements, the difference in the two single results is expressed as a percentage of the rhythmic mean of the two test results.

16.3.3 *Bias*—In test method terminology, bias is the difference between an average test value and the reference (or true) test property value. Reference values do not exist for this test method since the value (of the test property) is exclusively defined by the test method. Bias, therefore, cannot be determined.

TABLE 1 Precision for Hose Burst Strength[A]

Type Hose	No. of Laboratories[B]	Average Burst Pressure, MPa	Within Laboratories			Between Laboratories		
			Sr	*r*	*(r)*	*SR*	*R*	*(R)*
500	13	2.82	0.121	0.34	12.2	0.229	0.65	23.2
800	14	5.51	0.346	0.98	17.8	0.455	1.29	23.4
1600	13	15.2	0.558	1.58	10.4	1.21	3.42	22.5
2500	10	15.9	0.294	0.83	5.21	0.821	2.32	14.6
8000	9	75.7	1.53	4.32	5.71	2.67	7.58	10.05
14 000	11	134.4	3.51	9.92	7.38	4.08	11.54	8.59
20 000	10	179.8	5.74	16.2	9.01	12.1	34.2	19.01

Hose Pressure	No. of Laboratories	Average Burst Pressure, psi	Within Laboratory			Between Laboratories		
			Sr	*r*	*(r)*	*SR*	*R*	*(R)*
500	13	410	17.6	50	12.2	33	94	23.0
800	14	800	50	142	17.8	66	187	23.4
1600	13	2210	81	229	10.4	175	496	22.4
2500	10	2310	42	120	5.2	119	337	14.6
8000	9	10 980	222	627	5.7	388	1099	10.0
14 000	11	19 510	508	1440	7.4	592	1675	8.6
20 000	10	26 100	832	2356	9.0	1755	4967	19.0

[A] Symbols are defined as follows:

Sr = Within laboratory standard deviation.
r = Repeatability (in measurement units).
(r) = Repeatability (in percent).
SR = Between laboratory standard deviations.
R = Reproducibility (in measurement units).
(R) = Reproducibility (in percent).

[B] Number of laboratories participating in testing this type of hose.

17. Hydrostatic Pressure Tests

17.1 When tests for elongation, contraction, twist, warp, rise, and outside diametrical expansion are required, the hose shall be stretched out straight for inspection, and a pressure of 70 kPa (10 psi) applied. All original observations and measurements shall be taken at this pressure. Measurements shall be made using a graduated tape. The designated test pressure shall be applied at the rate specified in Section 15, without releasing the original pressure of 70 kPa (10 psi), and final measurements taken. The test pressure shall be applied for a minimum of 15 s prior to taking final measurements.

NOTE 5—The application of a pressure of 70 kPa (10 psi) prior to initial measurements is to assure that the hose is round, straight, and at manufactured length at the time of measurement. On very low pressure hose, such as ducting, this initial pressure might have a major effect on the attributes being measured. In such cases a lower initial pressure will provide a more valid evaluation of these attributes.

17.1.1 *Elongation and Contraction*—Measurements for the determination of elongation and contraction shall be based: *(1)* for hose, on distance between bench marks placed on hose; *(2)* for assemblies, on" free length," which is the distance between end connections on the hose. The results shall be reported as elongation if the final length is greater than the original length and as contraction if the final length is less than the original length. All results shall be reported to the nearest 1 %.

17.1.2 *Twist*—The amount of twist may be determined by noting, during the period the pressure is applied, the turns of the fitting at the free end of the hose. A crayon or pencil mark on the top surface of the hose adjacent to the closed coupling should be made so as to aid in determining the twist. Twist sometimes occurs quite rapidly. The amount of twist shall be reported to the nearest 45°. The direction of twist shall be reported as "right" or "left," a" right" twist being one in the direction that would tend to tighten the couplings.

17.1.3 *Warp*—Warping in hose tests is the deviation from a straight line drawn from fitting to fitting in a plane parallel to the surface on which the hose rests. The amount of warping is the maximum deviation of any portion of the hose from a straight line drawn from center to center of the fittings. The warp is measured as the distance from this line to the center line of the hose at the point of maximum deviation. A tightly stretched cord may be used to establish the straight line from center to center of the fittings. Results shall be reported to the nearest 5 mm or 0.25 in.

17.1.4 *Rise*—The amount the hose rises from the surface of the test table shall be considered as "rise" and recorded as such.

Copyright by the ASTM International
Wed Feb 02 01:45:27 2005

Results shall be reported to the nearest 5 mm or 0.25 in.

17.1.5 *Outside Diameter Expansion—Change in Circumference*—While the hose is under the specified original pressure, make three crayon or pencil marks equally spaced along its length. Measure the circumference at each of these marks, using a suitable tape, and record the average of these values. After the specified test pressure has been applied for the required time, again make circumference measurements at the same three places on the hose and record the average for these three readings. Calculate the expansion, and report results to the nearest 1 %.

17.2 When tests for elongation and contraction are required on wire-braided reinforced hose, such hose shall be tested by applying a pressure equivalent to the maximum pressure to which the hose is to be used for 30 s, at which time the length shall be measured. A second reading between 20 and 30 s after the pressure has been released to zero shall then be designated as the original length and the change in length (contraction or elongation) calculated as a percentage of the original length.

17.3 *Proof Pressure Tests (except for woven-jacketed fire hose)*—When proof pressure tests to determine leakage of hose or couplings are required, the proof pressure shall be applied in accordance with Section 15, and held 1 min. The proof pressure shall not exceed 50 % of the specified minimum bursting strength.

17.4 *Kink Tests*—When kink tests are required, each length of hose selected shall be filled with water with the petcock open to allow all air to escape. The petcock shall then be closed and the hose shall be kinked 450 mm (18 in.) from the coupling by tying the coupling back against the hose so that there will be a sharp kink. The pressure shall then be raised as specified in Section 15, to the required pressure and immediately released.

17.5 *Hold Test*—When a hold test is specified instead of a bursting test, pressure shall be applied as specified in Section 15 until the required pressure is reached. The specimen shall withstand the specified pressure for a 10-min period without bursting, leaking, or developing other defects. Specimens that have been subjected to this test shall not be considered fit for service.

17.6 *Precision and Bias*—No statement is made about either the precision or bias of the proof pressure, kink, and hold tests since the results merely indicate whether there is conformance to the criteria specified in the procedure. Data are being collected to determine the precision and bias of the other hydrostatic pressure tests.

18. Volumetric Expansion Test

18.1 *Apparatus*—The test apparatus used shall consist essentially of the following: A suitable source for the required fluid pressures, pressure gages, piping, valves, fittings in which the hose assembly may be mounted in a vertical position for application of pressure under controlled conditions, and a graduated buret for measuring the volume of liquid corresponding to the expansion of the hose under pressure. All piping and connections shall be smooth bore without recesses or offsets, so that all air may be freely removed from the system before running each test. The valves shall be of such design as to open and close with minimum displacement of liquid.[5] The apparatus shall be capable of applying the pressure at a rate of increase of 3 ± mPa/s [25 000 ± 10 000 lbf/(in^2·min)]. A suitable apparatus is shown in Fig. 1.

18.2 *Calibration of Apparatus*—The apparatus shall be tested prior to use to determine its calibration correction factor. For this purpose, 6.3-mm (0.25-in.)-diameter Bundy steel tubing or its equivalent shall be used in place of the hose assembly. Calibration correction factors shall be established at specified expansion pressure, and these shall be subtracted from the expansion readings obtained on the test specimens. The maximum permissible calibration correction factor shall be 0.08 cm^3 at 10 MPa (1500 psi).

18.3 *Procedure*—Carefully thread the test specimen into position on the apparatus in such a way as to provide a leak-proof seal, taking care to avoid twisting and to maintain the hose in a vertical position without tension while under pressure. Fill the tank, *C*, Fig. 1, with alcohol or distilled water, taking care that it is free of air or dissolved gases. Then open valve *B* and turn crank *D* to the left to allow the maximum amount of liquid to flow into the master cylinder. Next open valves *E, F*, and *G*, allowing the liquid to run from tank *C* through buret *K* until no air bubbles are seen in the buret. Removal of air bubbles may be facilitated by moving the hose back and forth. Then close valves *B* and *F* and raise the pressure in the hose to proof pressure for not more than 10 s. After inspection for leaks at the connections, completely release the pressure in the hose by opening valve *F*, which shall then be closed before proceeding with the next step. Now adjust the liquid level in buret *K* to zero by means of valve *G*. Turn crank *D* to the right until gage *A* shows the desired expansion pressure. Seal this pressure in the hose by closing valve *E*, after which take the expansion immediately by opening valve *F* and allowing the liquid in the expanded hose to rise in the buret. As soon as the liquid level has become constant, close valve *F* and take the reading on buret *K*. This operation shall be repeated so that the final reading taken on buret *K* will be the total of three expansions. This reading, divided by three minus the calibration factor, shall be considered as the final volumetric expansion of the hose. If the pressure in the hose should inadvertently be raised just prior to the expansion reading to a value above that specified, no reading shall be taken, but instead, the pressure shall be completely released and the procedure repeated.

18.4 *Precision and Bias*—Data are being collected to determine the precision and bias of the volumetric expansion test.

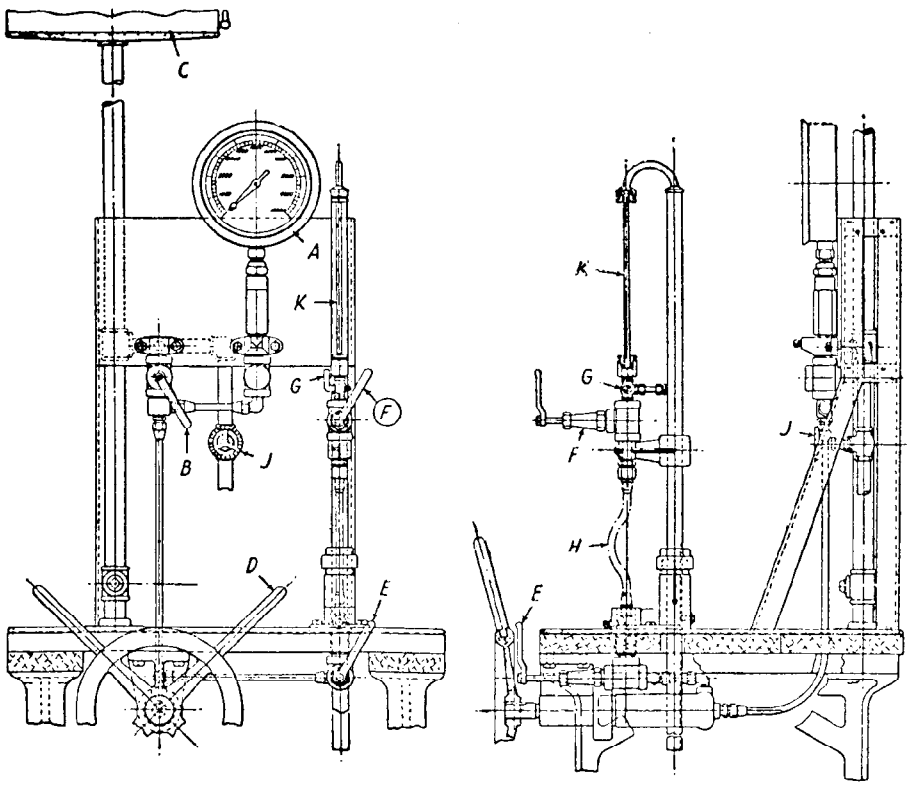
IMMERSION TESTS FOR CHANGE IN VOLUME AND DETERIORATION OF HOSE USED FOR PETROLEUM PRODUCTS

19. Types of Tests

19.1 Immersion tests for evaluating the change in volume and deteriorating effects of petroleum products on rubber hose consist of subjecting suitable test specimens from the rubber portion having known physical properties to the action of

[5] Crane Glove Valve No. 222X, or equivalent, has been found satisfactory for this purpose.

Copyright by the ASTM International
Wed Feb 02 01:45:28 2005



A—Pressure gage of 10 000-psi capacity.
B—Control valve from tank *C*.
C—Pressure-medium tank (vented on top).
D—Screw operated master cylinder.
E—Valve controlling line from master cylinder to hose.
F—Valve above hose.
G—Valve controlling flow into buret.
H—Hose in slack position.
J—Fluid line valve.
K—Buret graduated in 0.1 cm.[3]

FIG. 1 Apparatus for Expansion Test

selected test liquids by immersing the specimens completely in the liquid under controlled conditions for definite periods, after which the physical properties are again determined and the changes noted. Two types of test are covered, as follows:

19.1.1 *Change in Volume Test*—This type of test involves measurement of the change in volume of the rubber caused by the action of the liquid.

19.1.2 *Strength Deterioration Test*—This test measures changes in strength.

19.2 In any of the immersion tests, the choice of test method and test liquid depends upon the nature of the actual service and the petroleum product which is being used.

20. Test Liquids

20.1 Consider the reference fuels and oils described in the Standard Test Liquids section of Test Method D 471 as standard immersion test media for hose, and make the choice appropriate for the test from them unless other liquids are specifically required. In any case, report the liquid actually used with the test results.

21. Test Conditions

21.1 *Temperature*— Unless otherwise specified in the applicable specifications, the test temperatures shall be selected from the following, depending upon the anticipated service temperature:

Celsius Temperature	Fahrenheit Temperature
21 to 32	70 to 90
70 ± 2	158 ± 3.6
100 ± 2	12 ± 3.6
125 ± 2	257 ± 3.6
150 ± 2	302 ± 3.6

Generally when the test liquid is a fuel, for example, the temperature during the immersion period shall be 21 to 32°C (70 to 90°F). When the test liquid is an oil, any one of the three elevated temperatures may be used.

21.2 *Immersion Periods*—Immersion periods of 22 ± 0.25 h and 70 ± 0.7 h are recommended. Immersion tests shall be made in the absence of direct light.

22. Change in Volume Test

22.1 *Test Specimens*— The test specimens shall be rectangular rubber blocks, 50 by 25 mm (2 by 1 in.), having a thickness not over 1.6 mm (0.063 in.). They shall be cut from the hose and buffed on both faces only to the extent necessary to ensure smoothly buffed faces, except when the material is too thick, in which case the buffing shall be sufficient to reduce the specimens to 1.6 mm (0.063 in.). Three specimens shall be used for each test and the results averaged.

22.2 *Procedure*—Test in accordance with the Procedure for Change in Volume section of Test Method D 471.

Copyright by the ASTM International
Wed Feb 02 01:45:29 2005

22.3 *Calculation*— Calculate the percentage change in volume in accordance with the Calculation section of Test Method D 471.

23. Strength Deterioration Test

23.1 *Test Specimens*— Six dumbbell-shaped test specimens, prepared as described in Test Methods D 412, except minimum specimen thickness of 0.80 mm (0.031 in.), shall be required. Both faces of dumbbell shall be buffed.

23.2 *Procedure*—Test three specimens for tensile strength and elongation in accordance with Test Methods D 412, except average the results to give the properties of the rubber before immersion. Follow the Properties After Evaporation of Test Liquid section of Test Method D 471 for immersion procedure on the remaining three dumbbells. Express the deterioration shown by the difference between the determinations before and after immersion as a percentage of the original property.

23.3 *Precision and Bias*—The precision and bias of the test for deterioration on fluid immersion are given in Test Method D 471.

LOW-TEMPERATURE TESTS

24. Types of Tests

24.1 Low-temperature tests are made on complete sections of hose as described in Section 25, or on the tube and cover, as described in Section 26.

25. Low-Temperature Test on Complete Hose

25.1 *Conditioning*— Condition the hose while laid out straight in a cold chamber at the specified temperature for a period of 72 h. The cold chamber shall be capable of maintaining within it a uniform atmosphere of cold, dry air or a mixture of air and carbon dioxide at specified temperature (Note 6) within a tolerance of± 2°C (±3.6°F).

NOTE 6—Temperatures of – 40 and – 55°C (–40 and – 67°F) are commonly used.

25.2 *Procedure*—After conditioning and without removal from the cold chamber, bend the nose around a mandrel having a diameter ten times the outside diameter of the hose; it shall not break or crack. Bending shall be completed within 5 s. The mandrel size shall be by 25-mm (1-in.) increments. Where ten times the hose outside diameter is not an even 25 mm (1 in.), the next larger mandrel shall be used. This test shall be applicable to hose having a maximum nominal inside diameter of 76 mm (3 in.).

25.3 To aid in determining whether or not the hose has failed the bend test, the hose, after the test, may be placed under a hydrostatic pressure equivalent to the hose proof pressure.

26. Low-Temperature Test on Tube and Cover

26.1 *Apparatus*:

26.1.1 *Cold Chamber*— The cold chamber in which the test specimens are exposed to the low temperature shall be of sufficient size to contain the flexing fixture when loaded with specimens, and so arranged as to permit the operation of the fixture to bend specimens without removal from the chamber. It shall be capable of maintaining within it a uniform atmosphere of cold, dry air or a mixture of air and carbon dioxide at specified temperatures (Note 7) within a tolerance of± 2°C (±3.6°F).

26.1.2 *Flexing Fixture*— The flexing fixture shall consist of two parallel plates each having a width of at least 50 mm (2 in.), so supported in guides that they may be rapidly moved from a position 63.5 mm (2.5 in.) apart until they are separated by a distance of 25 mm (1 in.). Suitable clamping bars or devices shall be provided for holding the ends of the specimens for a distance of 6.3 mm (0.25 in.) at the corresponding edge of each plate so that, when mounted, the specimens form similar bent loops between the plates. A satisfactory flexing fixture is shown in Fig. 2.

26.2 *Test Specimens*— Specimens of hose tube and cover shall be taken from hose in accordance with Section 10. They

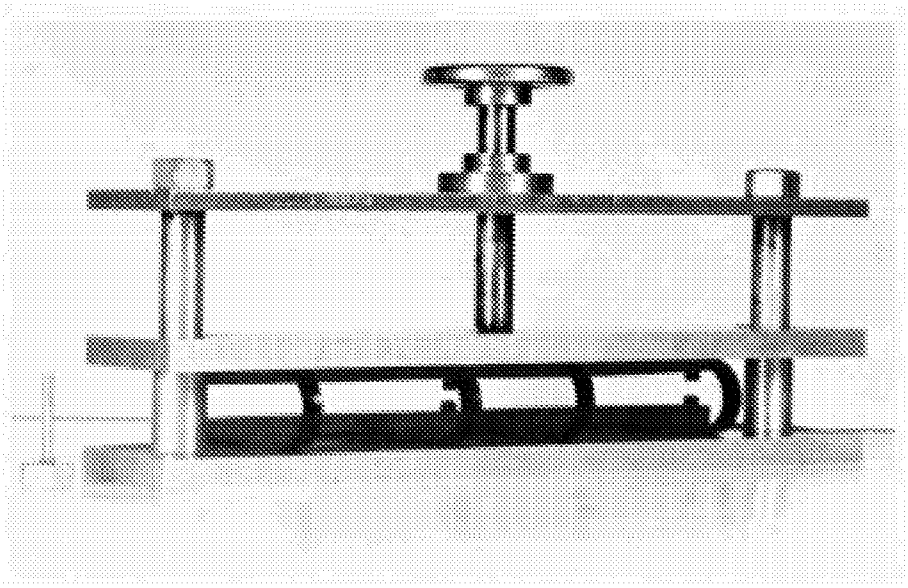


FIG. 2 Flexing Fixture for Low-Temperature Brittleness Test

Copyright by the ASTM International
Wed Feb 02 01:45:29 2005

shall be buffed to a maximum thickness of 2.3 mm (0.09 in.), then cut to shape, using die C as specified in Test Method D 412. At least two specimens from each tube and cover shall be tested.

26.3 *Procedure*—Mount the test specimens in loop position between the plates of the flexing fixture, with the enlarged ends spaced at least 3.2 mm (0.125 in.) apart and held in the clamps for a distance of 6.3 mm (0.25 in.). With the plates in the open position separated 63.5 mm (2.5 in.), place the fixture containing the specimens in the cold chamber and expose for the specified period to cold, dry air or a mixture of air and carbon dioxide at the specified temperature. The standard exposure period shall be 5 h (Note 7). At the termination of the exposure period and while still in the cold chamber, move the plates of the flexing fixture as rapidly as possible from the 63.5-mm (2.5-in.) distance of separation to a position where they are 25 mm (1 in.) apart. Then examine the specimens for fracture or visible cracks.

NOTE 7—Formerly two periods were specified, 96 h for natural rubber compounds and 5 h for synthetic rubber compounds. It was found that 5 h is adequate for either class of compounds within the intent of this test method.

26.4 *Results*—When two specimens are tested and neither one fractures nor shows cracks after being tested, the compound shall be considered as having passed the brittleness test. If both specimens crack, the compound shall be considered to have failed. If only one specimen fractures or cracks, the result is inconclusive and two additional specimens shall be tested. If either one of these cracks, the compound shall then be considered to have failed.

26.5 *Report*—The report shall include the following:

26.5.1 Results of the test, expressed as "passed" or "failed,"

26.5.2 Temperature of the cold chamber,

26.5.3 Duration of the exposure period,

26.5.4 Identification of the material tested, including description of any special treatment prior to test, and

26.5.5 Date of manufacture of the material, if known, and date of test.

AGING TESTS OF RUBBER

27. Types of Tests

27.1 *Air-Heat Test*— Determine the change in tensile strength and elongation of rubber parts of hose due to aging at atmospheric pressure and elevated temperature as described in Test Method D 573 or Test Method D 865, as specified in the detail specification. Unless otherwise specified in the detail specification, age the specimen at a temperature of 70 ± 2°C (158 ± 3.6°F) or 100 ± 2°C (212 ± 3.6°F) for 166 ± 1 h.

27.2 *Ozone Test*—Determine if surface cracks appear after exposure to ozone.

27.2.1 *Apparatus*:

27.2.1.1 *Ozone Test Chamber*, in accordance with Test Method D 1149.

27.2.1.2 *Jig or Holder*, that permits elongation of specimen.

27.2.1.3 *Mandrels*.

27.2.1.4 *Tie Wire*.

27.2.1.5 *Plugs or Caps*.

27.2.1.6 Any apparatus placed in the test chamber shall be non-ozone absorbant material.

27.2.2 *Procedure*:

27.2.2.1 *Specimen Preparation*—For hose 25 mm (1 in.) in inside diameter or smaller, bend a specimen of hose of full circumference around the mandrel and tie ends together where they cross one another. The mandrel shall have a diameter eight times the nominal outside diameter of the hose. The specimen length shall be about 250 mm (10 in.) longer than the mandrel circumference. Seal the ends of the hose with plugs or caps in such a manner that the reinforcement and inner liner will not be exposed to ozone. This will allow for more uniform control of ozone concentration in the test chamber, since ozone will not be consumed by material not under test. For hose over 25 mm in inside diameter, transversely remove a 25-mm width of the hose cover. Lightly buff the under side of the specimen to remove any reinforcement impressions. Place the specimen in a jig or holder and elongate 12.5 %.

27.2.2.2 *Conditioning*— The specimen under relevant stress shall be conditioned 48 to 72 h in a substantially ozone-free atmosphere maintained at the standard laboratory temperature.

27.2.2.3 *Exposure*—Unless otherwise specified, the specimen shall be exposed to 50 ± 5 mPa partial pressure of ozone in the test chamber at 40 ± 2°C (104± 3.6°F) for 70 to 72 h.

27.2.2.4 *Examination*— After exposure and prior to removal of specimen from mandrel or holder, examine for surface cracks under 2× magnification. For hose on mandrel, ignore the area adjacent to the tie point. For specimen in holder, examine the unbuffed side and ignore areas adjacent to clamp points.

27.2.3 *Report*—The report shall include the following:

27.2.3.1 Ozone concentration,

27.2.3.2 Exposure time,

27.2.3.3 Ambient test chamber temperature, and

27.2.3.4 Specimen surface condition (cracks or no cracks).

27.3 *Precision and Bias*—The precision and bias of the air heat test are given in Test Method D 573 and Test Method D 865. No statement is made about either the precision or bias of the ozone test since the results merely indicate whether there is conformance to the criteria specified in the procedure.

TENSION TEST

28. Summary of Test Method

28.1 This tension test consists of subjecting the hose assembly to increasing tension load in a suitable testing machine until failure occurs, either by separation of the specimen from the end fittings or by failure of the hose structure.

28.2 *Apparatus*:

28.2.1 *Tension Testing Machine*, conforming to the requirements of Practice E 4, and provided with an indicating device to give the total pull in newtons (pounds) at the conclusion of the test.

28.2.2 *Hose Assembly*, attached to the test machine by suitable fixtures so that the hose and fittings shall have a straight center line corresponding to the direction of the machine pull.

28.3 *Procedure*—Apply a steady tension load at a speed such that the moving head of the testing machine travels at the rate of 25± 3 mm (1.0 ± 0.1 in.)/min until failure. Record the

Copyright by the ASTM International
Wed Feb 02 01:45:29 2005

total load at the time of failure and note the type of failure.

28.4 *Precision and Bias*—Data are being collected to determine the precision and bias of the tension test.

29. Inspection

29.1 Make all tests and inspection at the place of manufacture prior to shipment, unless otherwise specified. The manufacturer shall afford the purchaser, inspector, or representative of the purchaser reasonable facilities to test and inspect the hose without charge.

29.2 The purchaser may make the tests and inspection to govern the acceptance or rejection of the material in his own laboratory or elsewhere. Make such tests and inspection at the expense of the purchaser not later than 60 days after receipt of the material.

30. Retests and Rejection

30.1 Any material that fails in one or more tests may be resampled and retested at the expense of the manufacturer. For this purpose select two additional samples from the hose. Failure of either of the retested samples shall be cause for final rejection.

30.2 Rejected material shall be disposed of as directed by the manufacturer and at his expense.

31. Keywords

31.1 rubber hose

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

ADOPTION NOTICE

ASTM D 471, "Standard Test Method for Rubber Property-Effect of Liquids", was adopted on 11 September 1998 for use by the Department of Defense (DoD). Proposed changes by DoD activities must be submitted to the DoD Adoption Activity: U.S. Army Tank-automotive and Armaments Command, ATTN: AMSTA-TR-D/210, Warren, MI 48397-5000. DoD activities may obtain copies of this standard from the Defense Automated Printing Service, Bldg. 4D (Customer Service), 700 Robbins Ave., Philadelphia, PA 19111-5094. The private sector and other Government agencies may purchase copies from the American Society for Testing and Materials (ASTM), 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959.

ASTM D 471 should be used instead of TT-S-735A, which was cancelled on 11 September 1998.

Designation: D 471 – 98$^{\epsilon 1}$

Standard Test Method for Rubber Property—Effect of Liquids[1]

This standard is issued under the fixed designation D 471; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

ϵ^1 NOTE—Table 3 was editorially updated in September 1999.

1. Scope

1.1 This test method covers the required procedures to evaluate the comparative ability of rubber and rubber-like compositions to withstand the effect of liquids. It is designed for testing: (*1*) specimens of vulcanized rubber cut from standard sheets (see Practice D 3182), (*2*) specimens cut from fabric coated with vulcanized rubber (see Test Method D 751), or (*3*) finished articles of commerce (see Practice D 3183). This test method is not applicable to the testing of cellular rubbers, porous compositions, and compressed sheet packing, except as described in 11.2.2.

1.2 ASTM Oils No. 2 and No. 3, formerly used in this test method as standard test liquids, are no longer commercially available and in 1993 were replaced with IRM 902 and IRM 903, respectively (see Appendix X1 for details).

1.3 This test method includes the following:

Change in Mass (after immersion)	Section 10
Change in Volume (after immersion)	Section 11
Dimensional-Change Method for Water-Insoluble Liquids and Mixed Liquids	Section 12
Change in Mass with Liquid on One Surface Only	Section 13
Determining Mass of Soluble Matter Extracted by the Liquid	Section 14
Change in Tensile Strength, Elongation and Hardness (after immersion)	Section 15
Change in Breaking Resistance, Burst Strength, Tear Strength and Adhesion for Coated Fabrics	Section 16
Calculation (of test results)	Section 17

1.4 The values stated in SI units are to be regarded as the standard. The values in parentheses are for information only.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Summary of Test Method

3.1 This test method provides procedures for exposing test specimens to the influence of liquids under definite conditions of temperature and time. The resulting deterioration is determined by measuring the changes in physical properties, such as stress/strain properties, hardness, and changes in mass, volume, and dimension, before and after immersion in the test liquid.

3.2 The precision statement in Section 19 is based on an interlaboratory test program run in 1981, using six different rubbers with ASTM Reference Fuels B, C, D[10] and ASTM Oils No. 1 and No. 3.

3.3 The precision statement in Appendix X2 is based on an interlaboratory test program conducted in 1993 to establish replacements for ASTM Oils No. 2 and No. 3. Because of the limited number of participating laboratories, only repeatability could be evaluated, and it was necessary to use pooled values of four No. 2 type oils (No. 2 plus three candidate replacement oils) and four No. 3 type oils (No. 3 plus three candidate replacement oils). Twelve rubbers were tested in this program.

4. Significance and Use

4.1 Certain rubber articles, for example, seals, gaskets, hoses, diaphragms, and sleeves, may be exposed to oils, greases, fuels, and other fluids during service. The exposure may be continuous or intermittent and may occur over wide temperature ranges.

4.2 Properties of rubber articles deteriorate during exposure to these liquids, affecting the performance of the rubber part, which can result in partial failure.

4.3 This test method attempts to simulate service conditions through controlled accelerated testing, but may not give any direct correlation with actual part performance, since service conditions vary too widely. It yields comparative data on which to base judgment as to expected service quality.

4.4 This test method is suitable for specification compliance testing, quality control, referee purposes, and research and development work.

5. Test Conditions

5.1 *Temperature and Immersion Periods*—Unless otherwise specified the test temperature and immersion period shall be as indicated in Table 1, depending upon the anticipated service conditions:

5.1.1 When the temperature of the testing room is other than the standard 23 ± 2°C (73 ± 4°F) the temperature of test shall be reported.

TABLE 1 Test Temperatures and Immersion Periods

Temperature in °C (°F)		Immersion Period, h
−75 ± 2 (−103 ± 4)	85 ± 2 (185 ± 4)	22
−55 ± 2 (−67 ± 4)	100 ± 2 (212 ± 4)	46
−40 ± 2 (−40 ± 4)	125 ± 2 (257 ± 4)	70
−25 ± 2 (−13 ± 4)	150 ± 2 (302 ± 4)	166
−10 ± 2 (14 ± 4)	175 ± 2 (347 ± 4)	670
0 ± 2 (32 ± 4)	200 ± 2 (392 ± 4)	1006
23 ± 2 (73 ± 4)	225 ± 2 (437 ± 4)	2998
50 ± 2 (122 ± 4)	250 ± 2 (482 ± 4)	4990
70 ± 2 (158 ± 4)		

5.1.2 The choice of the immersion period will depend upon the nature of the vulcanizate, the test temperature, and the liquid to be used. To obtain information on the rate of deterioration it is necessary to make determinations after several immersion periods. The tolerance for any immersion period shall be ±15 min or ±1 % of the immersion period, whichever is greater.

5.2 *Illumination*— Immersion tests shall be made in the absence of direct light.

6. Standard Test Liquids

6.1 For test purposes, it is usually desirable to use the liquid that will come into contact with the vulcanizate in service. For comparative tests with liquids of unknown or doubtful composition, samples of liquid from the same container or shipment shall be used. Many commercial products, particularly those of petroleum origin, are subject to sufficient variation that it is not practical to use them for test liquids. It is then advisable to use a standard test liquid, such as described in 6.1.1 and 6.1.2, covering the range of properties that may be encountered in the particular service.

6.1.1 *ASTM and IRM Oils*—The test shall be conducted in one of the petroleum-base ASTM or IRM oils (Note 1) specified in Table 2 that has its aniline point nearest that of the oil with which the vulcanizate is expected to come in contact in service except as indicated in 6.1.3.

NOTE 1—The aniline point of a petroleum oil appears to characterize the swelling action of that oil on rubber vulcanizates. In general, the lower the aniline point, the more severe the swelling action by the oil. The oils specified in Table 2 cover a range of aniline points commonly found in lubricating oils.

6.1.2 *ASTM Reference Fuels*—When gasolines or diesel fuels are to be encountered in service, the test shall be conducted in one of the ASTM reference fuels (Note 2) specified in Table 3, except as indicated in 6.1.3.

NOTE 2—The ASTM reference fuels in Table 3 have been selected to provide the maximum and minimum swelling effects produced by commercial gasolines. Reference Fuel A has a mild action on rubber vulcanizates and produces results of the same order as low swelling gasolines of the highly paraffinic, straight run type. Reference Fuels B, C, and D simulate the swelling behavior of the majority of commercial gasolines, with Reference Fuel C producing the highest swelling which is typical of highly aromatic premium grades of automotive gasoline.

TABLE 3 ASTM Reference Fuels

Fuel Type	Composition, Volume %
Reference Fuel A	Isooctane[A], 100
Reference Fuel B	Isooctane[A], 70; Toluene[A], 30
Reference Fuel C	Isooctane[A], 50; Toluene[A], 50
Reference Fuel D	Isooctane[A], 60; Toluene[A], 40
Reference Fuel E	Toluene[A], 100
Reference Fuel F	Diesel Fuel, Grade No. 2[B], 100
Reference Fuel G	Fuel D, 85; anhydrous denatured ethanol[C], 15
Reference Fuel H	Fuel C, 85; anhydrous denatured ethanol[C], 15
Reference Fuel I	Fuel C, 85; anhydrous methanol, 15
Reference Fuel K	Fuel C, 15; anhydrous methanol, 85

[A] Motor Fuels, Section 1, Test Method D 2699

[B] Specification D 975.

[C] Anhydrous ethanol denatured with unleaded gasoline (CDA formula No. 20), available from Archer-Daniels-Midland, P.O. Box 1470, Decatur, IL 62525.

TABLE 4 ASTM Service Liquids

Liquid	Composition
Service Liquid 101[A]	di-2 ethyl hexyl sebacate, 99.5 mass %; phenothiazine, 0.5 mass %
Service Liquid 102[B]	ASTM Oil No. 1, 95 mass %; hydrocarbon compound additive[C], 5 mass % (29.5–33.5 mass % sulfur, 1.5–2.0 mass% phosphorus, 0.7 mass % nitrogen)
Service Liquid 103[D]	tri-*n*-butyl phosphate, 100 mass %
Service Liquid 104[E]	ethylene glycol[F], 50 volume %; distilled water, 50 volume %
Service Liquid 105[G]	ASTM Reference Oil TMC 1006
Service Liquid 106[H]	ARM 200 (Aerospace Reference Material 200)

[A] Service liquid 101 is intended to simulate the swelling action of synthetic diester-type lubricating oils.

[B] Service liquid 102 approximates the swelling behavior of hydraulic oils.

[C] This hydrocarbon oil additive is available as Anglamol 99 from Lubrizol Corp., 29400 Lakeland Blvd., Wickliffe, OH 44092. Properties are as follows: Kinematic viscosity (mm^2/s [cSt]) at 99°C (210°F) – 9.70 ± 0.52 (Test Method D 445); Flash point COC °C (°F) – 45 (113) min (Test Method D 92); Density at 16°C (61°F) – 1.065 ± 0.015 (Test Method D 1217).

[D] Service liquid 103 simulates phosphate ester-type aircraft hydraulic oils.

[E] Service liquid 104 approximates the swelling behavior of automotive engine coolant.

[F] Ethylene glycol, reagent grade, shall be used.

[G] Service Liquid 105 is an API SJ/ILSAC GF-2 SAE 5W-30 reference engine oil meeting the requirements of ASTM D 4485 and SAE J 300. It is available from ASTM Test Monitoring Center, 6555 Penn Avenue, Pittsburgh, PA 15206–4489. Phone (412) 365–1000, Fax (412) 365–1047.

[H] Service Liquid 106 is intended to eventually replace Service Liquid 101 which is no longer readily available for purchase as a mixture. ARM 200 is available from SAE, 400 Commonwealth Drive, Warrendale, PA 15096.

Reference Fuel F (diesel fuel) swells rubber vulcanizates to a lesser extent than Reference Fuel B. Reference Fuels G, H, and I are fuel-alcohol blends (gasohol), which have a stronger swelling action than the corresponding fuel alone, where blends with methanol are more severe than blends with ethanol. Reference Fuel K, a methanol-rich blend, has a substantially weaker swelling action than that of the fuel used to prepare the blend. Reference Fuels I and K are also referred to as M15 and M85, respectively.

6.1.3 *Service Liquids*— Some commercial oils, fuels and other service liquids (see Table 4) are either non-petroleum or are compounded from special petroleum hydrocarbon fractions or mixtures of petroleum hydrocarbon fractions and other ingredients resulting in materials having properties beyond the range of the reference fluids listed in Table 2 and Table 3. Immersion tests of rubber vulcanizates that are to come into contact with such fluids should be made in the actual service liquid.

6.1.4 *Water*—Since the purity of water varies throughout the world, all water immersion tests are to be conducted in distilled or deionized water.

7. Preparation of Specimen

7.1 Except as otherwise specified in the applicable specifications, specimens shall be prepared in accordance with the requirements of Practices D 3182 and D 3183.

8. Apparatus

8.1 *For non-volatile liquids, a glass test tube*, having an outside diameter of 38 mm (1.5 in.) and an overall length of 300 mm (12 in.) fitted loosely with a stopper (see 8.2.1) shall be used.[11] Glass beads shall be used in the liquid as a bumper and to separate the specimens.

8.2 *For volatile liquids*, the test tube described in 8.1 shall be tightly fitted with a stopper (see 8.2.1) and a reflux condenser. An air-cooled reflux condenser shall be used for ASTM Oils No. 1[12,13] and No. 5 and for IRM 902[12,13] and

[11] Test tubes available under Part No. LGB24 and LGB24C (case of 30) from Edwin H. Benz Co. Inc., 73T Maplehurst Ave., Providence, RI 02908 or under Part No. LG226 from Precision Scientific, 2777 Washington Blvd., Bellwood, IL 60104, have been found suitable for this purpose.

[12] Information about ASTM Oil No. 1 is included in Research Report RR: D11-1004 and information about IRM 902 and IRM 903 in Research Report RR: D11-1069. Both reports are available from ASTM Headquarters.

Copyright by the ASTM International
Wed Feb 02 01:46:09 2005

IRM 903[12],[13] at test temperatures of 125°C (257°F) or more. This condenser shall be a glass tube, approximately 500 mm (20 in.) or longer, in length and 15 mm (0.6 in.) in outside diameter, tightly fitted to the immersion tube by means of a stopper (see 8.2.1). The bottom of the condenser tube shall project about 12 mm (0.47 in.) below the stopper. A suitable (watercooled) reflux condenser shall be used for water or other low-boiling liquids. Glass beads shall be used as in 8.1.

8.2.1 The stopper shall not contaminate the test liquid. When in doubt, cover the stopper with aluminum foil.

8.3 *Maintaining Test Temperatures*—The apparatus and method chosen to maintain the specified temperature during immersion testing varies with test conditions, requirements, and circumstances. Water baths, appropriate temperature transfer oil baths, hot air ovens Note 3, or aging blocks[14] may be used.

NOTE 3—When hot air ovens are used, it should be noted that contamination with volatile components of the immersion liquid may occur. This can affect test results, when the same ovens are subsequently used for hot air aging.

8.3.1 The preferred method for above room temperatures is the use of aging blocks, since they have the widest temperature capability.

8.3.2 *Ovens*—Type IIB ovens specified in Test Method E 145 are satisfactory for use through 70°C. For higher temperatures, Type IIA ovens are necessary.

8.3.2.1 The interior size shall be as follows or of an equivalent volume:

Interior size of air oven:	
min	300 by 300 by 300 mm (12 by 12 by 12 in.)
max	900 by 900 by 1200 mm (36 by 36 by 48 in.)

8.3.2.2 Provision shall be made for placing immersion test tubes in the oven without touching each other or the sides of the aging chamber and allowing proper air circulation around them.

8.3.2.3 The heating medium for the aging chamber shall be air circulated within it at atmospheric pressure.

8.3.2.4 The source of heat is optional but shall be located in the air supply outside of the aging chamber proper.

8.3.2.5 A recording thermometer located in the upper central portion of the chamber near the center of the aging specimens shall be provided to record the actual aging temperature.

8.3.2.6 Automatic temperature control by means of thermostatic regulation shall be used.

8.3.2.7 The following special precautions shall be taken in order that accurate, uniform heating is obtained in all parts of the aging chamber:

8.3.2.8 The heated air shall be thoroughly circulated in the oven by means of mechanical agitation. When a motor-driven fan is used, the air must not come in contact with the fan motor brush discharge because of danger of ozone formation.

8.3.2.9 Baffles shall be used as required to prevent local overheating and dead spots.

8.3.2.10 The thermostatic control device shall be so located as to give accurate temperature control of the heating medium. The preferred location is adjacent to the recording thermometer.

8.3.2.11 An actual check shall be made by means of maximum reading thermometers placed in various parts of the oven to verify the uniformity of the heating.

9. Test Specimens—Change in Mass or Volume

9.1 The standard specimen shall be rectangular, having dimensions of 25 by 50 by 2.0 ± 0.1 mm (1 by 2 by 0.08 ± 0.004 in.). Specimens from commercial articles shall be the thickness of the material as received when they are less than 2 mm (0.08 in.); otherwise they should be reduced to a thickness of 2.0 ± 0.1 mm (0.08 ± 0.004 in.). Data obtained on test specimens having different original thicknesses are not comparable.

10. Procedure for Change in Mass

10.1 Test three specimens of a single composition. Calculate the test results of the three specimens (see 17.1, Eq 1) and average the results. Weigh each specimen in air to the nearest 1 mg, record the mass as M_1, and immerse in the test tube (see 8.1) containing 100 cm^3 of the test liquid (see 10.1.1). Separate each test specimen from any adjacent test specimen and the walls of the test tube by approximately 6 mm (0.25 in.), for example, by perforated glass beads[15] as shown in Fig. 1. The

[13] ASTM Oil No. 1, IRM 902 and IRM 903 may be ordered from Penreco, 4426 East Washington Blvd., Los Angeles, CA 90023-4476. ASTM Oils No. 1, No. 5, IRM 902, and IRM 903 are distributed by R. E. Carroll, Inc., P.O. Box 5806, Trenton, NJ 08638-0806.

[14] Aging blocks, available under Model No. LGB9 (9 cavities) and LGB28 (28 cavities) from Edwin H. Benz Co., Inc., 73T Maplehurst Ave., Providence, RI 02908, have been found suitable for this purpose.

[15] Hollow perforated glass beads, available under Catalog No. 11-311C from Fisher Scientific Co., 711T Forbes Ave., Pittsburgh, PA 15219, have been found suitable for this purpose.

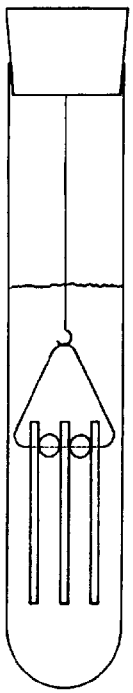

FIG. 1 Method of Separation

Copyright by the ASTM International
Wed Feb 02 01:46:09 2005

materials used to suspend and separate the specimens shall not affect the test liquid or the rubber.

10.1.1 Test liquids shall not be reused.

10.1.1.1 For non-volatile liquids, condition the test tube assembly at the specified temperature within the limits given in 5.1 for the specified length of time. A check of the actual temperature of the test liquid contained in the test tube should be made to ensure that the liquid is within the test temperature specified.

10.1.1.2 For volatile liquids, fit the test tube assembly with a reflux condenser (see 8.2) and condition at the specified temperature within the limits given in 5.1 for the specified length of time. A check of the actual temperature of the test liquid contained in the test tube should be made to ensure that the test liquid is within the test temperature specified.

10.2 After the immersion test has proceeded for the required length of time, remove the test specimens. If the immersion has been at elevated temperature, cool the test specimens to room temperature by transferring them to a cool clean portion of the test liquid for 30 to 60 min. Then dip the specimens quickly in acetone at room temperature, blot lightly with filter paper free of lint and foreign material, place them immediately in a tared, stoppered weighing bottle, and determine the mass after test, M_2, of each specimen to the nearest 1 mg. After weighing, again immerse the test specimen in the same test liquid (see 11.2.1) if data are desired on the progressive changes that occur with increasing time of immersion. It is important that each manipulation take place promptly with the least possible lapse of time. When utilizing liquids that tend to volatilize at room temperature, no more than 30 s should elapse between removal from the test liquid and stoppering the weighing bottle.

10.3 Relatively viscous oils may be difficult to remove from the specimens with a quick acetone dip and blotting or even more vigorous wiping when the specimens are cooled in the test liquid after immersion; this can yield erroneous test results. Since these oils do not readily volatilize, specimens may be cooled by suspending them for about 30 min in air at room temperature shielded from draft, after removal from the immersion liquid at the test temperature. This will allow the majority of the oil to drip off the surface of the specimen. Then proceed with the acetone dip and blotting as described in 10.2. Report when this alternate method of specimen cooling is used.

11. Procedure for Change in Volume

11.1 *Water Displacement Method for Water-Insoluble Liquids and Mixed Liquids*—Test three specimens, calculate the test results for each specimen (see 17.2, Eq 2), and average the results. Obtain the mass M_1 of each specimen (see 11.2.2) in air, to the nearest 1 mg, and then obtain the mass M_2 of each specimen immersed in distilled water at room temperature. Quickly dip each specimen in alcohol (methanol or ethanol) to remove water (see 11.2.3), blot dry with filter paper free of lint and foreign material, and place in the immersion apparatus described in 8.1 or 8.2. Add 100 cm^3 of liquid (see 10.1.1) to the test tube and complete the immersion test as described in 10.1.1.1 or 10.1.1.2. At the end of the required immersion period, remove each specimen from the test tube. Cool the specimens to room temperature by transferring them to a cool, clean portion of the test liquid for 30 to 60 min, then dip quickly in acetone at room temperature, blot lightly with filter paper free of lint or foreign material, place in a tared, stoppered weighing bottle, weigh, and record the mass as M_3. Remove each specimen from the bottle, weigh in distilled water, and record the mass as M_4 in immediate consecutive order to determine the water displacement after immersion (see 11.2.2 and Note 4). When data on progressive changes with increasing time of immersion are desired, dip each specimen after weighing in alcohol (methanol or ethanol) to remove water (see 11.2.3), blot dry with filter paper free of lint and foreign material, and again immerse in the same test liquid (see 11.2.1). It is important that each manipulation following removal of the test specimen from the test medium take place promptly with the least possible lapse in time. When utilizing liquids that tend to volatilize at room temperature, no more than 30 s should elapse between removal from the test liquid and stoppering the weighing bottle, and no more than an additional 30 s between removal from the weighing bottle and immersion in water.

11.2 Relatively viscous oils may be difficult to remove from the specimens with a quick acetone dip and blotting or even more vigorous wiping when specimens are cooled in the test liquid after immersion; this can yield erroneous test results. Refer to 10.3 for an alternate method of specimen cooling.

11.2.1 Report if fresh test liquid is used, which can be a requirement for certain test methods or specifications.

11.2.2 It is important that all air bubbles clinging to the test specimen be removed before weighing in distilled water. If, in the course of weighing, air bubbles appear on the surface of the specimen, or the computed volume changes 0.5 % in 5 min, the specimen is too porous to permit volume determination in this manner. In that case, the initial volume of the specimen, if the latter is a simple geometrical solid, can be determined from the overall dimensions by employing an appropriate mensuration formula, and the same procedure followed in determining the volume after the immersion test; or, if volume increase occurs principally in the thickness dimension, a simple change in thickness may be substituted for change in volume. If, in the course of weighing the test specimen floats, AISI No. 316 stainless steel can be used as ballast to immerse the test specimen in the test liquid. In those cases where ballast is needed to submerge the specimen, the following procedure may be used.

11.2.2.1 Weigh the test specimen with ballast in water,

11.2.2.2 Weigh the ballast alone in water, and

11.2.2.3 Determine the difference between the weighings, and proceed with the calculations.

11.2.3 The acetone dip before and after immersion shall be omitted when water is employed as the test medium.

NOTE 4—A jolly balance, adequately shielded from air currents, may be used for making these determinations. When utilizing liquids that tend to volatilize at room temperature, no more than 30 s should elapse between removal from the test liquid and completion of the weighing operation.

11.3 *Displacement Method for Water-Soluble Liquids and Mixed Liquids (Other Than Water)*—For immersion liquids that are readily miscible with water or react with it, the water displacement method as described in 11.1 may not be suitable. For such liquids that are not too viscous or volatile at room

Copyright by the ASTM International
Wed Feb 02 01:46:10 2005

temperature, weighings for M_2 and M_4 may be made in the immersion liquid instead of water with weighing for M_4 made in a fresh portion of the immersion liquid. These values are then used in calculating volume change using Eq 2 in 17.2. If this is not practicable, the water displacement method shall be used, except that the final weighing for M_4 is omitted and change in volume is calculated according to Eq 3 in 17.2. This formula may be only approximate if the immersion liquid is a mixture, because the density of the absorbed liquid may differ from that of the bulk. Also the density of any matter extracted from the rubber may differ from that of the immersion liquid.

12. Dimensional-Change Method for Water-Insoluble Liquids and Mixed Liquids

12.1 *Dimensional Change Method*—Measure the original length and width of three test specimens used in 11.1 to the nearest 0.5 mm (0.02 in.) using an average of three measurements in each direction recording the dimensions as L_0 and W_0, respectively. Measure the thickness of each test piece using a dial micrometer as described in 6.3 of Test Methods D 412, and record as T_0. Place specimens in the immersion apparatus described in 8.1 and 8.2. Add 100 cm^3 of liquid (see 10.1.1) to the test tube and complete the immersion test as described in 10.1.1.1 or 10.1.1.2. At the end of the required immersion period, remove each specimen from the test tube and bring to room temperature by transferring them to a cool clean portion of the test liquid for 30 to 60 min. Dip the specimens quickly in acetone at room temperature, blot lightly with filter paper free of lint and foreign material, and promptly remeasure as described above, recording the immersed length, width, and thickness as L, W, and T, respectively. If the immersion liquid tends to volatilize at room temperature, the measurements should be completed within 30 s after removing the test specimens from the liquid at room temperature. Calculate test results according to Eq 4 in 17.3 and report the average of three specimens.

13. Procedure for Change in Mass with Liquid on One Surface Only

13.1 *Scope*—This test method provides a procedure for exposing thin sheet materials (rubber-coated fabrics, diaphragms, etc.) that are in contact with the immersion liquid on only one surface under definite conditions of time and temperature.

13.2 *Test Specimen*— A disk 60 mm (2.4 in.) in diameter and thickness of thin sheet or rubber-coated fabric being tested.

13.3 *Apparatus*—The essential features are illustrated in Fig. 2 and consist of a base plate, *A*, an open-ended cylindrical chamber, *B*, which is held tightly against the test specimen, *C*, by wing nuts, *D*, mounted on bolts, *E*. During the test, the opening in the top of the chamber is tightly closed by a suitable plug, *F*.

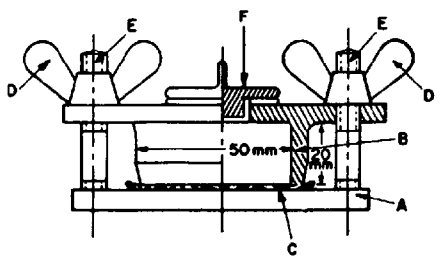

FIG. 2 Surface Immersion Apparatus

13.4 *Procedure*—Weigh the test specimen in air to the nearest 1 mg, record as M_1, and place in the apparatus as indicated in Fig. 2. Fill the chamber of the apparatus with the test liquid to a depth of 15 mm (0.6 in.), replace plug *F* and complete the test at the specified conditions as described in 5.1 and 5.2. At the end of the required immersion period, bring the apparatus to standard room temperature, remove the test liquid, and release the test specimen. Remove any excess liquid from the surface by wiping or blotting with filter paper free of lint and foreign material and place the specimen immediately in a tared, stoppered weighing bottle. Determine the mass of the specimen to the nearest 1 mg and record as M_2. When the immersion liquid tends to volatilize at room temperature, no more than 30 s should elapse between removal of the test specimen from the liquid and stoppering the weighing bottle. Use Eq 5 in 17.4 to calculate test results. If more than one specimen of the same composition is tested, report the result as the average.

14. Procedure for Determining Mass of Soluble Matter Extracted by the Liquid

14.1 This test method is applicable for immersions in volatile-type immersion liquids, such as ASTM reference fuels (see 6.1.2). Conduct the immersions as described in 10.1, 10.1.1.1, and 10.1.1.2. Test three specimens of a single composition, and report the result as the average. The extracted matter can be determined either by the difference in mass of the specimen before and after immersion or by evaporating the test liquid and weighing the non-volatile residue (Note 5). The mass is determined in air to the nearest 1 mg.

NOTE 5—Both methods are subject to error. Results obtained by the mass difference of specimens before and after immersion can be affected by possible oxidation of the material during immersion. Results obtained by evaporating the test liquid may be affected by partial loss of volatile extracted material during drying. The method of choice will depend on the material under test and the test conditions. For example, the evaporation method would be preferred if further testing is to be done on the extracted matter.

14.2 *Mass-Difference Method*—At the end of the required immersion period, remove the test specimens from the test tube and dry to a constant mass at a temperature of approximately 40°C (104°F) and an absolute pressure of 20 kPa (150 mm Hg). Record the original mass of the test specimen before immersion as M_1, the mass after immersion as M_2, and express the change in mass as a percentage of the original mass, using Eq 6 in 17.5. Report the results as the average if more than one specimen of the same composition is tested.

14.3 *Evaporation Method*—Transfer the liquid from the test tube in which the three test specimens have been immersed to a suitable vessel, wash the specimens in the test tube three times with 25 cm^3 of fresh liquid and transfer the liquid to the same vessel. Evaporate the liquid and dry the residue to a constant mass under an absolute pressure of 20 kPa (150 mm Hg) and a temperature of approximately 40°C (104°F). Record the sum of the original mass of three specimens before

Copyright by the ASTM International
Wed Feb 02 01:46:10 2005

immersion as ΣM_1, the mass of the dried residue as M_3, and express M_3 as a percentage of ΣM_1, using Eq 7 in 17.5.

15. Changes in Tensile Strength, Elongation, and Hardness

15.1 *Original Properties*—The original tensile strength, ultimate elongation (Test Methods D 412, Die C) and hardness (Test Methods D 1415 or D 2240) shall be determined, using three specimens cut from the sheet or article adjacent to those that are to be immersed in the liquid. Report results in accordance with the appropriate test method.

15.2 *Immediate Deteriorated Properties*—For determining the tensile strength, ultimate elongation, and hardness, prepare three test specimens from flat vulcanized sheets 2.0± 0.1 mm (0.08 ± 0.004 in.) in thickness (see 9.1) using Die C of Test Methods D 412. Measure the thickness of each test specimen, place the specimens in the test tube described in 8.1, and add 150 cm^3 of liquid (see 10.1.1) to the test tube. Complete the immersion period in accordance with 10.1.1.1 or 10.1.1.2. At the end of the required immersion period, remove the specimens from the test tubes and cool immediately to room temperature in a fresh sample of the same liquid for 30 to 60 min. Then quickly dip each sample in acetone and blot lightly with filter paper that is free of lint and foreign material and immediately apply bench marks.

15.2.1 Determine the tensile strength and ultimate elongation in accordance with Test Methods D 412, using the original unimmersed thickness or cross-sectional area (see 17.6, Eq 8). Determine the hardness of each immersed specimen in accordance with Test Methods D 1415 or D 2240. The time interval between removal from the cool liquid and testing shall be not less than 2 nor more than 3 min.

15.2.2 It may be desirable to calculate the tensile strength based on the swollen cross-sectional area. In that case Eq 9 in 17.6 shall be used. Report when this method of calculation is employed.

15.3 Relatively viscous oils may be difficult to remove from the specimens with a quick acetone dip and blotting or even more vigorous wiping when specimens are cooled in the test liquid after immersion; this can yield erroneous test results. Refer to 10.3 for an alternate method of specimen cooling.

15.4 *Properties After Evaporation of Test Liquid*—This test method is applicable for immersions in volatile-type immersion liquids, such as ASTM reference fuels (see 6.1.2). For determining the tensile strength, ultimate elongation, and hardness of specimens after evaporation of the immersion liquid, immerse the specimens in the test liquid in accordance with 15.2. At the end of the required immersion time, remove the specimens and, if necessary, cool them to room temperature in a fresh sample of the same liquid for 30 to 60 min.

15.4.1 For room temperature drying, suspend the specimens for 4 ± 0.25 h in air at ambient conditions shielded from drafts. After the drying period apply bench marks and determine tensile strength and ultimate elongation in accordance with Test Methods D 412 using the original thickness or cross-sectional area of the untreated specimens (see 17.6, Eq 8) and hardness according to Test Methods D 1415 or D 2240.

15.4.2 For determining properties after complete evaporation of the test liquid, suspend specimens after the 4-h airdrying cycle at room temperature for 20 h ± 15 min at 70 ± 2°C (158 ± 4°F) in a circulating-air oven. After the heat drying cycle, remove the specimens from the oven, allow them to cool to room temperature and measure the required physical properties as described in 15.4.1. Report when the heat drying procedure is used.

15.5 The tensile strength and ultimate elongation after immersion and evaporation also can be expressed as percent change from the original values, using Eq 10 in 17.6, and hardness in unit change from the original value, according to Eq 11 in 17.6.

16. Changes in Breaking Resistance, Burst Strength, Tear Strength, and Adhesion for Coated Fabrics

16.1 *Original Properties*—The original properties for breaking resistance, burst strength, tear strength, and adhesion shall be determined in accordance with Test Method D 751, using the specified number of specimens cut from the coated fabric adjacent to those that are to be immersed in the liquid, or, if necessary, from other pieces of coated fabric that were produced from the same lot(s) of materials under the same conditions.

16.2 *Immediate Deteriorated Properties*—For determining breaking resistance, burst strength, tear strength, and adhesion, prepare the number of specimens specified for each parameter in Test Method D 751. Place the specimens in the test tube described in 8.1 and add 150 cm^3 of liquid (see 10.1.1) to the test tube. Complete the immersion test in accordance with 10.1.1.1 or 10.1.1.2. At the end of the required immersion period, remove the specimens from the test tubes, and cool immediately to room temperature in a fresh sample of the same liquid for 30 to 60 min. Then quickly dip each specimen in acetone and blot lightly with filter paper that is free of lint or foreign material. Measure the required physical properties in accordance with Test Method D 751 (see 17.7). The time interval between removal from the cool liquid and testing shall be not less than 2 min nor more than 3 min.

16.3 Relatively viscous oils may be difficult to remove from the specimens with a quick acetone dip and blotting or even more vigorous wiping when specimens are cooled in the test liquid after immersion; this can yield erroneous test results. Refer to 10.3 for an alternate method of specimen cooling.

16.4 *Properties After Evaporation of Volatile Test Liquid*—For determining breaking resistance, burst strength, tear strength, and adhesion of specimens after evaporation of a volatile immersion liquid, such as ASTM reference fuels (see 6.1.2), immerse the specimens in the test liquid in accordance with 15.2. At the end of the required immersion time, remove the specimens, suspend them for 2 h ± 5 min at ambient conditions shielded from draft and then place them in a circulating-air oven at a temperature of 70 ± 2°C (158 ± 4°F) for a period of 2 h ± 5 min. At the end of the drying period, remove the specimens from the oven, allow them to cool to room temperature and measure the required physical properties in accordance with Test Method D 751 (see 17.7). The time interval between removal from the oven and testing shall be not less than 1 h nor more than 2 h.

16.5 If desired, report results after immersion and evaporation in percent change from the original property values, as described in 15.5.

17. Calculation

17.1 Calculate the percent change in mass as follows (Section 10):

$$\Delta M, \% = \frac{(M_2 - M_1)}{M_1} \cdot 100 \quad (1)$$

where:
ΔM = change in mass, %,
M_1 = initial mass of specimen in air, g, and
M_2 = mass of specimen in air after immersion, g.

17.2 Calculate the percent change in volume as follows (Section 11):

$$\Delta V, \% = \frac{(M_3 - M_4) - (M_1 - M_2)}{(M_1 - M_2)} \cdot 100 \quad (2)$$

$$\Delta V, \% = \frac{(M_3 - M_1)}{d(M_1 - M_2)} \cdot 100 \quad (3)$$

where:
ΔV = change in volume, %,
M_1 = initial mass of specimen in air, g,
M_2 = initial mass of specimen in water, g,
M_3 = mass of specimen in air after immersion, g,
M_4 = mass of specimen in water after immersion, g, and
d = density of immersion liquid at standard laboratory room temperature, Mg/m^3.

17.3 Calculate the percent change in dimensions as follows (Section 12):

$$\Delta L, \% = \frac{(L - L_0)}{L_0} \cdot 100 \quad (4)$$

where:
ΔL = change in length, %,
L_0 = initial length of specimen, mm, and
L = length of specimen after immersion, mm.

Calculate the percent change in width, ΔW, and thickness, ΔT, accordingly.

17.4 Calculate the change in mass for single surface exposure as follows (Section 13):

$$\Delta M_A, \text{ kg/m}^2 = \frac{(M_2 - M_1)}{A} \cdot 1000 \quad (5)$$

where:
ΔM_A = change in mass per unit surface area, kg/m^2,
M_1 = initial mass of specimen in air, g,
M_2 = mass of specimen in air after exposure to the test liquid, g, and
A = area of the specimen in actual contact with the test liquid, mm^2.

17.5 Calculate percent extracted soluble matter as follows (Section 14):

$$M_E, \% = \frac{(M_1 - M_2)}{M_1} \cdot 100 \quad (6)$$

$$M_E, \% = \frac{M_3}{\Sigma M_1} \cdot 100 \quad (7)$$

where:
M_E = extracted soluble matter, %,
M_1 = initial mass of specimen in air, g,
M_2 = mass of specimen in air after immersion and drying, g,
ΣM_1 = sum of the initial mass of three specimens in air, g, and
M_3 = mass of the residue in air after evaporating and drying the immersion liquid of three specimens, g.

17.6 Calculate tensile strength of the specimens both on immediate deteriorated properties and properties after evaporation of the test liquid as described in the Calculation section of Test Methods D 412.

17.6.1 Based on the original unstretched cross-sectional area:

$$TS_o = \frac{F}{A} \quad (8)$$

17.6.2 Based on the swollen unstretched cross-sectional area:

$$TS_s = \frac{F}{A\left(1 + \frac{\Delta V}{100}\right)^{2/3}} \quad (9)$$

17.6.3 To express tensile strength and ultimate elongation after immersion as a percentage change from the original properties, use the following formula:

$$\Delta P, \% = \frac{P_i - P_o}{P_o} \cdot 100 \quad (10)$$

17.6.4 Calculate hardness change after immersion in hardness units:

$$\Delta H = H_i - H_o \quad (11)$$

where:
TS_o = tensile stress based on original unstretched cross-sectional area,
TS_s = tensile stress based on swollen unstretched cross-sectional area,
F = observed force,
A = original unstretched cross-sectional area of the test specimen before immersion,
ΔV = volume swell after immersion, %,
ΔP = change in property (tensile strength and ultimate elongation) after immersion, %,
P_o = original property before immersion,
P_i = property after immersion,
ΔH = hardness change after immersion, units,
H_o = original hardness before immersion, units, and
H_i = hardness after immersion, units.

17.7 Calculate breaking resistance, burst strength, tear strength, and adhesion both on the immediate deteriorated properties and properties after evaporation of volatile test liquid as described in Test Method D 751. If desired, results may also be expressed in percentage change after immersion as detailed in 17.6.3.

18. Report

18.1 State that the test was conducted in accordance with Test Method D 471 and report the following:

Copyright by the ASTM International
Wed Feb 02 01:46:11 2005

18.1.1 Description of the sample and its origin,

18.1.2 Date and temperature of testing room (see 5.1),

18.1.3 Duration, temperature, and date of vulcanization of test specimens,

18.1.4 Dates of the various periods of exposure,

18.1.5 Immersion liquid used,

18.1.6 Temperature of exposure,

18.1.7 Exposure period,

18.1.8 All observed and recorded data, to include the type of properties being reported,

18.1.9 Results calculated in accordance with Section 17,

18.1.10 Statement of condition of exposed specimens from visual and manual examination,

18.1.11 Report which test method was used for determination of hardness, and

18.1.12 Any deviations from standard test methods.

19. Precision and Bias [16]

19.1 This precision and bias section deals with property changes in tensile strength, ultimate elongation, hardness, and volume after immersion in test liquids and has been prepared in accordance with Practice D 4483. Refer to this practice for terminology and other statistical calculation details.

19.2 The precision results in this precision and bias section give an estimate of the precision of this test method with the materials used in the particular interlaboratory test program as described in the following paragraphs. The precision parameters should not be used for acceptance or rejection testing of any group of materials without documentation that the parameters are applicable to the particular group of materials and the specific testing protocols of the test method.

19.3 A Type 1 interlaboratory test program was evaluated in 1981 using six different vulcanized rubber compounds (materials). These compounds were prepared in one laboratory and test specimens were distributed to nine participating laboratories. Each laboratory prepared and purchased from approved sources, the liquids and fuels, or both, used for testing. A test result (as used for these calculations) is the average of three individual test specimen values. Each laboratory conducted tests (that is, obtained one test result) on each of two days. Both repeatability and reproducibility are therefore short term; a period of a few days separates test results.

[16] Details and supporting data of the precision evaluation program are available in a research report from ASTM Headquarters. Request RR: D11-1069.

19.4 The results of the precision evaluation are given in Table 5 and Table 6 for each of the six rubbers or materials for immersion tests in (*1*) Reference Fuels B, C and D, for 70 h at 23 ± 2°C (73 ± 4°F), and (*2*) ASTM Oil No. 2 and ASTM Oil No. 3 for 70 h at 150 ± 2°C (302 ± 4°F).

19.5 The precision is given in terms of *Sr, r, SR*, and *R* for four measured physical properties: (*1*) percent change in tensile strength, (*2*) percent change in ultimate elongation (that is, percent change in percent elongation), (*3*) hardness change in hardness units, and (*4*) percent change in volume of the test specimen. No values are given for (*r*) and (*R*), the normal precision parameters used to express relative precision because numerous average values for properties (*1*), (*2*), and (*4*) are near zero, thus resulting in extremely large (*r*) and (*R*) values. These large values are essentially meaningless for precision comparisons when average values are near zero.

19.6 The precision of the test method may be expressed in the following statements that use an appropriate value of *r* and *R*. The appropriate value is that value of *r* or *R*, associated with a mean level in the tables closest to the mean level under consideration for any immersion liquid or rubber, for any test result for a similar material in routine testing operations.

19.7 *Repeatability*— The repeatability, *r*, of this test method has been established as the appropriate value tabulated in Table 5 and Table 6. Two single test results, obtained under normal test method procedures, that differ by more than this tabulated *r* (for any given level) must be considered as derived from different or nonidentical sample populations.

19.8 *Reproducibility*— The reproducibility, *R*, of this test method has been established as the appropriate value tabulated in Table 4 through Table 6. Two single test results obtained in two different laboratories, under normal test method procedures, that differ by more than the tabulated *R* (for any given value) must be considered to have come from different or nonidentical sample populations.

19.9 *Bias*—In test terminology, bias is the difference between an average test value and the reference (or true) value. Reference values do not exist for this test method since the value (of the test property) is exclusively defined by the test method. Bias, therefore, cannot be determined.

APPENDIXES

(Nonmandatory Information)

X1. REPLACEMENT OF ASTM OILS NO. 2 AND NO. 3 WITH IRM 902 AND IRM 903

X1.1 ASTM Oils No. 2 and No. 3 became subject to cancer hazard warning label requirements under the OSHA Hazard Communication Standard, published November 25, 1983. This contributed to the discontinuation of commercial production in 1990.

X1.2 ASTM Subcommittee D11.15 on Degradation Testing began a program in 1985–1986 to establish replacements for these oils, with the objective to match the action on vulcanized rubbers as closely as possible, while eliminating the need for cancer hazard labeling (negative modified Ames Test). An interlaboratory test program (ITP) was organized in 1993 with six candidate oils as No. 2 and No. 3 replacements from three different suppliers, using twelve different types of vulcanized rubbers. As a result of this ITP, two oils from Calumet Lubricants Company were selected as best (but not equivalent) matches for the ASTM oils, and confirmed independently by ASTM Subcommittee D11.15 and the SAE Committee on Automotive Rubber Specifications (SAE-CARS). Calumet No. 2, the replacement for No. 2 oil, provided a closer match than Calumet No. 3, the replacement for No. 3 oil. The two oils were established as industry reference materials, IRM 902 (Calumet No. 2, replacement for ASTM Oil No. 2) and IRM 903 (Calumet No. 3, replacement for ASTM Oil No. 3).

X1.2.1 Details of the ITP are described in Research Report

Copyright by the ASTM International
Wed Feb 02 01:46:11 2005

RR: D11-1069, which can be obtained from ASTM headquarters. A precision statement on volume swells generated in this test program is given in Appendix X2.

X1.3 Since the inventory of ASTM Oils No. 2 and No. 3 was depleted by the end of 1993, Committee D-11 published Emergency Standard ES 27 in 1994 to address the replacement with IRM 902 and IRM 903.

X2. PRECISION AND BIAS—TEST PROGRAM FOR THE REPLACEMENT OF ASTM OILS NO. 2 AND NO. 3

X2.1 This precision statement was prepared using data from the comprehensive ITP evaluation program conducted in 1993 to establish replacement oils for ASTM Oils No. 2 and No. 3. Because of the limited number of laboratories (three), only within-laboratory variation or repeatability could be evaluated. Some terminology used in this appendix is contained in Practice D 4483. Refer to Practice D 4483 for background details.

X2.2 In the evaluation program twelve compounds were tested in groups of four; each group of four was tested by three laboratories. There are only three duplicates (one duplicate set of tests in each laboratory) for an estimate of within-laboratory variation for any combination of rubber and oil. This is an inadequate number of degrees of freedom (DF) for such an estimate. However, a reasonable assumption may be made that for any given rubber, the true test variation with each of the four oils is equivalent. On this basis for any candidate set of the four oils, the three DF estimates of test standard deviation for each of the four oils may be pooled to obtain a twelve DF estimate of test standard deviation. The within-laboratory precision of this appendix is based on such pooled values.

X2.3 The precision results are given in Table X2.1 for percent volume swell. This is the only property that was evaluated for precision, since it shows the highest sensitivity to variation.

X2.4 Table X2.1 lists the repeatability standard deviation, *Sr*; the repeatability, *r*, in units of % volume swell, the relative repeatability, (*r*), which is a percent of a percent for volume swell measurements, and for completeness, the coefficient of variation, CV, in %. The mean volume swell values range from near zero to about 160 %. The precision parameters also display a wide range. Regression and graphical analysis reveals that (*1*) there is a direct (positive slope) log-log relationship for *Sr* versus mean volume swell, and (*2*) an inverse (negative slope) relationship between the relative repeatability (*r*) and mean volume swell. These relationships apply to both sets of data and to the combined data sets.

X2.5 The results of Table X2.1 may be applied to within-laboratory data comparisons using either IRM 902 or IRM 903 for any commercial or proprietary compound by selecting the Table X2.1 rubber closest to the commercial compound and selecting the level of volume swell value in Table X2.1 closest to the measured volume swell of the commercial rubber.

TABLE X2.1 Precision Data for Within-Laboratory Variation

NOTE 1—*Sr* = repeatability standard deviation, *r* = repeatability = 2.83 × *Sr*, (*r*) = repeatability on relative basis (percent of percent), and *CV* = coefficient of variation, % = (*Sr*/Mean) × 100.

Rubber	Change in Volume, % (Pooled Values)				
	Mean	*Sr*	*r*	(*r*)	*CV*

TPV	79.5	1.92	5.43	6.8	2.4
VMQ	43.4	2.30	6.52	15.0	5.3

[A] Pooled results for No. 2 oil plus three candidate replacements.
[B] Pooled results for No. 3 oil plus three candidate replacements.

X2.5.1 Two test results of the commercial rubber that differ by more than the tabulated *r* or (*r*) values as selected by the above process, must be considered to have come from different sample populations (that is, be significantly different).

X2.5.2 Alternatively normal testing operations should produce values for duplicate test results that are within the *r* and (*r*) intervals as selected by the above process.

X2.6 Bias reference values do not exist for this type of testing, since the value of the test property is defined exclusively by the test method. Bias, therefore, cannot be determined.

Designation: D 1600 – 99

An American National Standard

Standard Terminology for Abbreviated Terms Relating to Plastics[1]

This standard is issued under the fixed designation D 1600; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope *

1.1 The purpose of this terminology is to provide uniform contractions of terms relating to plastics. Abbreviated terminology has evolved through widespread common usage. This compilation has been prepared to avoid both the occurrence of more than one abbreviated term for a given plastics term and multiple meanings for abbreviated terms.

1.2 The scope of these abbreviated terms includes plastics terms pertaining to composition and relating to type or kind according to mode of preparation or principle distinguishing characteristics. Also included are abbreviated terms for terms relating to copolymers, blends and alloys of plastics, and additives such as plasticizers, fillers, etc.

NOTE 1—A code relating to the composition of rubbers is given in Practice D 1418.

1.3 No attempt is made here to systematize formally a shorthand terminology for polymers. Terminology, including nomenclature, codes, symbols, and formula designations for use in scientific literature in the field of natural and synthetic polymers, are being studied and standardized by the International Union of Pure and Applied Chemistry.[2]

1.4 These abbreviated terms are by no means all-inclusive of plastics terminology. They represent, in general, those terms that have come into established use. Since it is recognized that abbreviated terms serve no useful purpose unless they are generally accepted and used, no attempt has been made to establish a rigorous code for devising standard abbreviated terms. This would result in awkward departures from established usage of existing and accepted abbreviated terms and lead to cumbersome combinations in the future, which would not be likely to receive widespread acceptance. The abbreviated terms now in use have grown naturally out of the need for convenient, readily comprehended shorthand for long chemical names. This process can be expected to continue along the natural lines of least resistance and will serve as a basis for further standardization as the need arises. A general guide for the preparation of abbreviated terms appears desirable, however, to facilitate more organized and uniform standardization in the future. An appendix is attached, which suggests a uniform way to prepare abbreviated terms.

1.5 Note that the uppercase letter F should be used to designate phosphate and that other elements may also be designated F.

1.6 An abbreviated term (FR) and code numbers are provided to identify classes of materials used as flame retardants added to plastics. The system is provided for use in situations where marking of plastics products is desired.

NOTE 2—Many of the abbreviated terms, codes, numbers, and symbols in ISO 1043 parts 1 through 3 and in ISO/DIS 1043-4 are the same as the corresponding item in ASTM D 1600. D 1600 includes a number of abbreviated terms that are not in ISO 1043.

3.2.1.1 *Discussion*—Flame retardants may be incorporated in plastics as additives (external flame retardant) or as chemical groups in the base polymer by use of reactive intermediates in the polymerization process (internal flame retardant). The code numbers in this standard are restricted to external flame retardants.

4. Terms and Abbreviated Terms

4.1 *Plastics and Resins:*[6]

Term	Abbreviated Term
Acrylonitrile/butadiene plastics	AB
Acrylonitrile-butadiene-acrylate plastics	ABA
Acrylonitrile-butadiene-styrene plastics	ABS
Acrylonitrile-chlorinated polyethylene-styrene plastics	ACPES
Acrylonitrile-ethylene-styrene plastics	AES
Acrylonitrile-methyl acrylate-acrylonitrile-butadiene rubber	AMAB
Acrylonitrile-methyl methacrylate plastics	AMMA
Acrylonitrile-styrene-acrylate plastics	ASA
Acrylonitrile/ethylene-propylene-diene/styrene	AEPDMS
Aromatic polyester	ARP
Carboxymethyl cellulose	CMC
Casein	CS
Caseine-formaldehyde resin	CSF
Cellulose acetate	CA
Cellulose acetate-butyrate	CAB
Cellulose acetate propionate	CAP
Cellulose formaldehyde	CEF
Cellulose nitrate	CN
Cellulose plastics, general	CE
Cellulose propionate	CP
Cellulose triacetate	CTA
Chlorinated poly(vinyl chloride)	CPVC
Chlorinated polyethylene	CPE
Cresol-formaldehyde resin	CF
Epoxy, epoxide	EP
Ethyl cellulose	EC
Ethylene-chlorotrifluoroethylene copolymer	E-CTFE
Ethylene-ethyl acrylate plastics	EEA
Ethylene-methacrylic acid plastics	EMA
Ethylene-propylene polymer	EPM
Ethylene-propylene-diene plastics	EPD
Ethylene-tetrafluoroethylene copolymer	ETFE
Ethylene-vinyl acetate plastics	EVA
Ethylene-vinyl alcohol copolymer	EVOH
Fluorocarbon perfluoromethoxy	MPA
Furan formaldehyde resin	FF
High density polyethylene plastics	HDPE
High impact-resistant polystyrene	HIPS
Impact resistant polystyrene	IPS
Linear low density polyethylene plastics	LLDPE
Linear medium density polyethylene plastics	LMDPE
Liquid crystal polymer	LCP
Low density polyethylene plastics	LDPE
Medium density polyethylene plastics	MDPE
Melamine-formaldehyde resin	MF
Melamine/phenol-formaldehyde resin	MPF
Methacrylate-butadiene-styrene plastics	MBS
Methyl cellulose	MC
Methyl methacrylate-acrylonitrile-butadiene-styrene resin	MMABS
Nylon (see also polyamide)	PA
Perfluoro(alkoxy alkane)	PFA
Perfluoro(ethylene-propylene) copolymer	FEP
Perfluoromethoxy resin	MFA
Phenol-formaldehyde resin	PF
Phenol-furfural resin	PFF
Poly(acrylic acid)	PAA
Poly(allyl diglycol carbonate)	PADC
Poly(aryl ether ketone)	PAEK
Poly(butyl acrylate)	PBA
Poly(butylene terephthalate)	PBT
Poly(cyclohexylenedimethylene cyclohexandicarboxylate), glycoland acid comonomer	PCCE
Poly(cyclohexylenedimethylene terephthalate)	PCT
Poly(cyclohexylenedimethylene terephthalate), acid comonomer	PCTA
Poly(cyclohexylenedimethylene terephthalate), glycol	PCTG
Poly(diallyl phthalate)	PDAP
Poly(ester urethane)	PAUR
Poly(ether block amide)	PEBA
Poly(ether sulfone)	PES
Poly(ether urethane)	PEUR
Poly(ethylene oxide)	PEOX
Poly(ethylene terephthalate)	PET[6]
Poly(ethylene terephthalate) glycol comonomer	PETG
Poly(methyl methacrylate)	PMMA
Poly(methyl methacrylimide)	PMMI
Poly(methyl-α-chloroacrylate)	PMCA
Poly(phenyl sulfone)	PPSU
Poly(phenylene ether) (or Poly(phenylene oxide), a deprecated term)	PPE
Poly(phenylene sulfide)	PPS
Poly(phenylene sulfone)	PPSU
Poly(propylene oxide)	PPOX
Poly(vinyl acetate)	PVAC
Poly(vinyl alcohol)	PVOH
Poly(vinyl butyral)	PVB
Poly(vinyl carbazole)	PVK
Poly(vinyl chloride)	PVC
Poly(vinyl chloride-acetate)	PVCA
Poly(vinyl fluoride)	PVF
Poly(vinyl formal)	PVFM
Poly(vinyl pyrrolidone)	PVP
Poly(vinylidene chloride)	PVDC
Poly(vinylidene fluoride)	PVDF
Poly(ε-caprolactone)	PCL
Poly-4-methylpentene-1	PMP
Poly-α-methylstyrene	PMS
Poly-p-oxybenzoate	POB
Polyacrylonitrile	PAN
Polyamide (nylon)	PA
Polyamide 11	PA11
Polyamide 12	PA12
Polyamide 1212	PA1212
Polyamide 46	PA46
Polyamide 6	PA6
Polyamide 610	PA610
Polyamide 612	PA612
Polyamide 66	PA66
Polyamide 69	PA69
Polyamide-imide	PAI
Polyarylate	PAR
Polyaryl amide	PARA
Polyarylether	PAE
Polyarylsulfone	PASU
Polybutadiene-acrylonitrile	PBAN
Polybutadiene-styrene	PBS
Polybutene-1	PB
Polycarbonate	PC
Polychlorotrifluoroethylene	PCTFE
Polyester alkyd (or polyacrylate)	PAK
Polyetheretherketone	PEEK
Polyetheretherketoneketone	PEEKK
Polyetherketonetherketoneketone	PEKEKK

[6] To prevent any confusion with or misuse of the registered trademark, PET® Milk, the guidelines of 8.1 shall be followed.

Term	Abbreviated Term
Polyetherketoneketone	PEKK
Polyetherimide	PEI
Polyetherketone	PEK
Polyethylene	PE
Poly(ethylene naphthalate)	PEN
Polyhydroxy butyrate	PHB
Polyimide	PI
Polyimidesulfone	PISU
Polyisobutylene	PIB
Polyisocyanurate	PIR
Polyketone	PK
Polymethacrylimide	PMI
Polyoxymethylene, polyacetal	POM
Polyphthalamide	PPA
Polypropylene	PP
Polystyrene	PS
Polysulfone	PSU
Polytetrafluoroethylene	PTFE
Polyurethane	PUR
Saturated polyester plastic	SP
Silicone plastics	SI
Styrene-α-methylstyrene plastic	SMS
Styrene-acrylonitrile plastic	SAN
Styrene-butadiene plastic	SB
Styrene-butadiene-styrene block copolymer	SBS
Styrene-ethylene/butylene-styrene block copolymer	SEBS
Styrene-ethylene/propylene-styrene block copolymer	SEPS
Styrene-isoprene-styrene block copolymer	SIS
Styrene-maleic anhydride plastics	S/MA
Styrene-rubber plastics	SRP
Thermoplastic elastomer	TPE
Thermoplastic elastomer, ether-ester	TEEE
Thermoplastic elastomer, fully crosslinked elastomer alloy	FCEA
Thermoplastic elastomer, highly crosslinked thermoplastic vulcanizate	HCTPV
Thermoplastic elastomer, olefinic	TEO
Thermoplastic elastomer, polyether block amide	PEBA
Thermoplastic elastomer, styrenic	TES
Thermoplastic elastomer styrenic, saturated	TESS
Thermoplastic elastomer styrenic, unsaturated	TESU
Thermoplastic polyester	TPES
Thermoplastic polyester:	
Copolyester [poly(aryl terephthalate)]	ARP
Polyarylate [poly(aryl terephthalate)]—liquid crystal polymer	PAT
Thermoplastic polyurethane	TPU
Thermoplastic polyurethane, reinforced	RTPU
Thermoset polyurethane	TSPU
Ultra-high molecular weight polyethylene	UHMWPE
Unsaturated polyester	UP
Urea-formaldehyde resin	UF
Vinyl chloride-ethylene resin	VCE
Vinyl chloride-ethylene-methyl acrylate resin	VCEMA
Vinyl chloride-ethylene-vinyl acetate resin	VCEVAC
Vinyl chloride-methyl acrylate resin	VCMA
Vinyl chloride-methyl methacrylate resin	VCMMA
Vinyl chloride-octyl acrylate resin	VCOA
Vinyl chloride-vinyl acetate resin	VCVAC
Vinyl chloride-vinylidene chloride resin	VCVDC
Vinylidene fluoride	VDF

4.2 *Blends and Alloys of Plastics*:

Term	Abbreviated Term
Acrylonitrile-butadiene-acrylate plastics + poly(methyl methacrylate)	ABA+PMMA
Acrylonitrile-butadiene-acrylate plastics+poly(vinyl chloride)	ABA+PVC
Acrylonitrile-butadiene-acrylate plastics+polycarbonate	ABA+PC
Acrylonitrile-butadiene-styrene plastics+poly(vinyl chloride)	ABS+PVC
Acrylonitrile-butadiene-styrene plastics+polyphenylene sulfone	ABS+PPSU
Acrylonitrile-butadiene-styrene plastics+polytetrafluoroethylene	ABS+PTFE
Acrylonitrile-butadiene-styrene plastics+styrene maleic anhydride	ABS+SMA

Polycarbonate+poly(ethylene terephthalate)	PC+PET[6]
Polycarbonate+polyethylene	PC+PE
Polycarbonate+styrene-maleic anhydride	PC+SMA
Polycarbonate+thermoplastic polyurethane	PC+TPU
Polyoxymethylene+polytetrafluoroethylene	POM+PTFE
Polyoxymethylene+rubber	POM+RBR
Polyurethane+polyisocyanate	PUR+PIR
Styrene-maleic anhydride plastics+impact resistant polystyrene	SMA+IPS
Thermoplastic elastomer-chlorinated ethylene alloy	TECEA

4.3 *Plastic and Resin Additives*:

Term	Abbreviated Term
Alkylsulfonic acid ester	ASE
Benzyl butyl phthalate	BBP
Benzyl octyl adipate (benzyl 2-ethylhexyl adipate)	BOA
Benzyl octyl phthalate (benzyl 2-ethylhexyl phthalate)	BOP
Di-n-octyl phthalate	DNOP
Dibutylphthalate	DBP
Dibutyl sebacate	DBS
Dicapryl phthalate	DCP
Dicylohexyl phthalate	DCHP
Didecyl phthalate	DDP
Diethyl phthalate	DEP
Diheptyl phthalate	DHP
Dihexyl phthalate	DHXP
Diisobutyl phthalate	DIBP
Diisodecyl adipate	DIDA
Diisodecyl phthalate	DIDP
Diisoheptyl phthalate	DIHP
Diisohexyl phthalate	DIHXP
Diisononyl adipate	DINA
Diisononyl phthalate	DINP
Diisooctyl adipate	DIOA
Diisooctyl phthalate	DIOP
Diisopentyl phthalate	DIPP
Diisotridecyl phthalate	DITDP
Dimethyl phthalate	DMP
Dinonyl phthalate	DNP
Dioctyl adipate	DOA
Dioctyl azelate	DOZ
Dioctyl isophthalate (di-2-ethylhexyl isophthalate)	DOIP

Wed Feb 02 01:47:35 2005

Term	Abbreviated Term
Dioctyl phthalate	DOP
Dioctyl sebacate	DOS
Dioctyl terephthalate (di-2-ethylhexyl terephthalate)	DOTP
Diphenyl octyl phosphate	DPOF
Diphenyl cresyl phosphate	DPCF
Diphenyl 2-ethylhexyl phosphate	DPOF
Diundecyl phthalate	DUP
Epoxidized linseed oil	ELO
Epoxidized soya bean oil	ESO
Heptyl nonyl undecyl adipate	HNUA
Heptyl nonyl undecyl phthalate	HNUP
Hexyl octyl decyl adipate	HXODA
Hexyl octyl decyl phthalate	HXODP
n-Octyl decyl trimellitate	ODTM
Nonyl undecyl adipate	NUA
Nonyl undecyl phthalate	NUP
Octyl decyl adipate	ODA
Octyl decyl phthalate	ODP
Tetraoctyl pyromellitate (tetra-2-ethylhexyl pyromellitate)	TOPM
Trichloroethyl phosphate	TCEF
Tricresyl phosphate (or tritolyl phosphate)	TCF
Triheptyl trimellitate	THTM
Triisooctyl trimellitate	TIOTM
Trioctyl phosphate	TOF
Trioctyl trimellitate (tri-2-ethylhexyl trimellitate)	TOTM
Triphenyl phosphate	TPP
Trixylyl phosphate	TXF

4.4 *Monomers*:

Term	Abbreviated Term
Allyl diglycol carbonate	ADC
Chlorotrifluoroethylene	CTFE
Diallyl chlorendate (diallyl ester of 1,4,5,6,7,7-hexa chlorobicyclo-(2,2,1)-5-heptene-2,3 -dicarboxylic acid)	DAC
Diallyl fumarate	DAF
Diallyl isophthalate	DAIP
Diallyl maleate	DAM
Diallyl phthalate (diallyl orthophthalate)	DAP
Methyl methacrylate	MMA
Tetrafluoroethylene	TFE
Triallyl cyanurate	TAC

4.5 *Miscellaneous Plastics Terms*:

Term	Abbreviated Term
General purpose	GP
Single stage	SS

NOTE 3—When listing one or more components, the order preferably should be in decreasing amount by mass. There are situations, however, where long standing usage indicates that this recommendation should not be followed. An example is ETFE.

5. Full List by Term and Abbreviated Term

Term	Abbreviated Term
Acrylonitrile-butadiene-acrylate plastics+poly(methyl methacrylate)	ABA+PMMA
Acrylonitrile-butadiene-acrylate plastics+poly(vinyl chloride)	ABA+PVC
Acrylonitrile-butadiene-acrylate plastics+polycarbonate	ABA+PC
Acrylonitrile-butadiene-acrylate plastics	ABA
Acrylonitrile-butadiene-styrene plastics+poly(vinyl chloride)	ABS+PVC
Acrylonitrile-butadiene-styrene plastics+polyphenylene sulfone	ABS+PPSU
Acrylonitrile-butadiene-styrene plastics+polytetrafluoro-ethylene	ABS+PTFE
Acrylonitrile-butadiene-styrene plastics+styrene maleic anhydride	ABS+SMA
Acrylonitrile-butadiene-styrene plastics+thermoplastic polyurethane	ABS+TPU
Acrylonitrile/butadiene plastics	AB
Acrylonitrile-butadiene-styrene plastics+polyamide	ABS+PA
Acrylonitrile-butadiene-styrene plastics+polycarbonate	ABS+PC
Acrylonitrile-chlorinated polyethylene-styrene plastics	ACPES
Acrylonitrile-ethylene-styrene plastics	AES
Acrylonitrile-methyl acrylate-acrylonitrile-butadiene rubber	AMAB
Acrylonitrile-methyl methacrylate plastics	AMMA
Acrylonitrile-styrene-acrylate plastics+poly(methyl methacrylate)	ASA+PMMA
Acrylonitrile-styrene-acrylate plastics+poly(vinyl chloride)	ASA+PVC
Acrylonitrile-styrene-acrylate plastics	ASA
Acrylonitrile-styrene-acrylate plastics+polycarbonate	ASA+PC
Acrylonitrile/ethylene-propylene-diene/styrene plastics	AEPDMS
Alkylsulfonic acid ester	ASE
Allyl diglycol carbonate	ADC
Aromatic polyester	ARP
Benzyl butyl phthalate	BBP
Benzyl octyl adipate (benzyl 2-ethylhexyl adipate)	BOA
Benzyl octyl phthalate (benzyl 2-ethylhexyl phthalate)	BOP
Carboxymethyl cellulose	CMC
Casein	CS
Caseine-formaldehyde resin	CSF
Cellulose acetate	CA
Cellulose acetate-butyrate	CAB
Cellulose acetate-propionate	CAP
Cellulose formaldehyde	CEF
Cellulose nitrate	CN
Cellulose plastics, general	CE
Cellulose propionate	CP
Cellulose triacetate	CTA
Chlorinated poly(vinyl chloride)	CPVC
Chlorinated polyethylene	CPE
Chlorotrifluoroethylene	CTFE
Cresol-formaldehyde resin	CF
Di-n-octyl phthalate	DNOP
Diallyl chlorendate (diallyl ester of 1,4,5,6,7,7-hexachloro-bicyclo-(2,2,1)-5-heptene-2,3-dicarboxylic acid)	DAC
Diallyl fumarate	DAF
Diallyl isophthalate	DAIP
Diallyl maleate	DAM
Diallyl phthalate (diallyl orthophthalate)	DAP
Dibutyl phthalate	DBP
Dibutyl sebacate	DBS
Dicapryl phthalate	DCP
Dicyclohexyl phthalate	DCHP
Didecyl phthalate	DDP
Diethyl phthalate	DEP
Diheptyl phthalate	DHP
Dihexyl phthalate	DHXP
Diisobutyl phthalate	DIBP
Diisodecyl adipate	DIDA
Diisodecyl phthalate	DIDP
Diisoheptyl phthalate	DIHP
Diisohexyl phthalate	DIHXP
Diisononyl adipate	DINA
Diisononyl phthalate	DINP
Diisooctyl adipate	DIOA
Diisooctyl phthalate	DIOP
Diisopentyl phthalate	DIPP
Diisotridecyl phthalate	DITDP
Dimethyl phthalate	DMP
Dinonyl phthalate	DNP
Dioctyl adipate	DOA
Dioctyl azelate	DOZ
Dioctyl isophthalate (di-2-ethylhexyl isophthalate)	DOIP
Dioctyl phthalate	DOP
Dioctyl sebacate	DOS

Term	Abbreviated Term
Dioctyl terephthalate (di-2-ethylhexyl terephthalate)	DOTP
Diphenyl 2-ethylhexyl phosphate	DPOF
Diphenyl cresyl phosphate	DPCF
Diphenyl octyl phosphate	DPOF
Diundecyl phthalate	DUP
Epoxidized linseed oil	ELO
Epoxidized soya bean oil	ESO
Epoxy, epoxide	EP
Ethyl cellulose	EC
Ethylene-chlorotrifluoroethylene copolymer	E-CTFE
Ethylene-ethyl acrylate plastics	EEA
Ethylene-methacrylic acid plastics	EMA
Ethylene-propylene polymer	EPM
Ethylene-propylene-diene plastics	EPD
Ethylene-tetrafluoroethylene copolymer	ETFE
Ethylene-vinyl acetate plastics	EVA
Ethlene-vinyl alcohol copolymer	EVOH
Fluorocarbon perfluoromethoxy	MPA
Fully crosslinked elastomeric alloy	FCEA
Furan-formaldehyde resin	FF
General purpose	GP
Heptyl nonyl undecyl adipate	HNUA
Heptyl nonyl undecyl phthalate	HNUP
Hexyl octyl decyl adipate	HXODA
Hexyl octyl decyl phthalate	HXODP
High density polyethylene plastics	HDPE
High impact-resistant polystyrene	HIPS
Impact resistant polystyrene	IPS
Linear low density polyethylene plastics	LLDPE
Linear medium density polyethylene plastics	LMDPE
Liquid crystal polymer	LCP
Low density polyethylene plastics	LDPE
Medium density polyethylene plastics	MDPE
Melamine-formaldehyde resin	MF
Melamine/phenol-formaldehyde resin	MPF
Methacrylate-butadiene-styrene plastics	MBS
Methyl cellulose	MC
Methyl methacrylate	MMA
Methyl methacrylate-acrylonitrile-butadiene-styrene resin	MMABS
n-Octyl decyl trimellitate	ODTM
Nonyl undecyl adipate	NUA
Nonyl undecyl phthalate	NUP
Nylon (See also *polyamide*)	PA
Octyl decyl adipate	ODA
Octyl decyl phthalate	ODP
Perfluoro(alkoxy alkane)	PFA
Perfluoro(ethylene-propylene) copolymer	FEP
Perfluoromethoxy resin	MFA
Phenol-formaldehyde resin	PF
Phenol-furfural resin	PFF
Poly(acrylic acid)	PAA
Poly(allyl diglycol carbonate)	PADC
Poly(aryl ether ketone)	PAEK
Poly(butyl acrylate)	PBA
Poly(butylene terephthalate)	PBT
Poly(butylene terephthalate)+poly(ethylene terephthalate)	PBT+PET[6]
Poly(butylene terephthalate)+poly(phenylene ether)	PBT+PPE
Poly(butylene terephthalate)+rubber	PBT+RBR
Poly(cyclohexylenedimethylene cyclohexandicarboxylate), glycol and acid comonomer	PCCE
Poly(cyclohexylenedimethylene terephthalate)	PCT
Poly(cyclohexylenedimethylene terephthalate), acid comonomer	PCTA
Poly(cyclohexylenedimethylene terephthalate), glycol	PCTG
Poly(diallyl phthalate)	PDAP
Poly(ester urethane)	PAUR
Poly(ether block amide)	PEBA
Poly(ether sulfone)	PES
Poly(ether urethane)	PEUR
Poly(ethylene naphthalate)	PEN
Poly(ethylene oxide)	PEOX
Poly(ethylene terephthalate)	PET[6]
Poly(ethylene terephthalate)+poly(methyl methacrylate)	PET[6] +PMMA
Poly(ethylene terephthalate)+poly(phenylene sulfone)	PET[6]+PPSU
	PET[6]+RBR
Poly(ethylene terephthalate), glycol comonomer	PETG
Poly(methyl methacrylate)	PMMA
Poly(methyl methacrylimide)	PMMI
Poly(methyl-α-chloroacrylate)	PMCA
Poly(phenyl sulfone)	PPSU
Poly(phenylene ether) (or poly(phenylene oxide), a deprecated term)	PPE
Poly(phenylene ether)+impact resistant polystyrene	PPE+IPS
Poly(phenylene sulfide)	PPS
Poly(phenylene sulfide)+polytetrafluoroethylene	PPS+PTFE
Poly(phenylene sulfone)	PPSU
Poly(propylene oxide)	PPOX
Poly(vinyl acetate)	PVAC
Poly(vinyl alcohol)	PVOH
Poly(vinyl butyral)	PVB
Poly(vinyl carbazole)	PVK
Poly(vinyl chloride)	PVC

Poly(vinyl chloride-acetate)	PVCA
Poly(vinyl fluoride)	PVF
Poly(vinyl formal)	PVFM
Poly(vinyl pyrrolidone)	PVP
Poly(vinylidene chloride)	PVDC
Poly(vinylidene fluoride)	PVDF
Poly(ε-caprolactone)	PCL
Poly-4-methyl pentene-1	PMP
Poly-α-methylstyrene	PMS
Poly-p-oxybenzoate	POB
Polyacrylonitrile	PAN
Polyamide (amorphous) blend	PA +
Polyamide (nylon)	PA
Polyamide 11	PA11
Polyamide 12	PA12
Polyamide 1212	PA1212
Polyamide 46	PA46
Polyamide 6	PA6
Polyamide 610	PA610
Polyamide 612	PA612
Polyamide 66	PA66
Polyamide 69	PA69
Polyamide plastics+ethylene-methacrylic acid (ionomer)	PA+EMA
Polyamide+poly(phenylene ether)	PA+PPE
Polyamide+polyethylene	PA+PE
Polyamide+rubber	PA+RBR
Polyamide+styrene-acrylonitrile plastics	PA+SAN
Polyamide-imide	PAI
Polyarylate	PAR
Polyaryl amide	PARA
Polyarylether	PAE
Polyarylsulfone	PASU
Polybutadiene-acrylonitrile	PBAN
Polybutadiene-styrene	PBS
Polybutene-1	PB
Polycarbonate	PC
Polycarbonate+poly(butylene terephthalate)	PC+PBT
Polycarbonate+poly(ethylene terephthalate)	PC+PC+PET[6]
Polycarbonate+polyethylene	PC+PE
Polycarbonate+styrene-maleic anhydride	PC+SMA
Polycarbonate+thermoplastic polyurethane	PC+TPU
Polychlorotrifluoroethylene	PCTFE
Polyester alkyd (or polyacrylate)	PAK
Polyester, thermoplastic; polyarylate [poly(aryl terephthalate)]—liquid crystal polymer	PAT
Polyetheretherketone	PEEK

Term	Abbreviated Term
Polyetheretherketoneketone	PEEKK
Polyetherketonetherketoneketone	PEKEKK
Polyetherketoneketone	PEKK
Polyetherizmide	PEI
Polyetherketone	PEK
Polyethylene	PE
Polyhydroxy butyrate	PHB
Polyhydroxy butyrate-polyhydroxy valerate	PHBV
Polyimide	PI
Polyimidesulfone	PISU
Polyisobutylene	PIB
Polyisocyanurate	PIR
Polyketone	PK
Polymethacrylimide	PMI
Polyoxymethylene+polytetrafluoroethylene	POM+PTFE
Polyoxymethylene+rubber	POM+RBR
Polyoxymethylene, polyacetal	POM
Polyphthalamide	PPA
Polypropylene	PP
Polystyrene	PS
Polysulfone	PSU
Polytetrafluoroethylene	PTFE
Polyurethane	PUR
Polyurethane+polyisocyanate	PUR+PIR
Saturated polyester plastic	SP
See TCF	TTP
Silicone plastics	SI
Single stage	SS
Styrene-α-methylstyrene plastic	SMS
Styrene-acrylonitrile plastic	SAN
Styrene-butadiene plastics	SB
Styrene-butadiene-styrene block copolymer	SBS
Styrene-ethylene/butylene-styrene block copolymer	SEBS
Styrene-ethylene/propylene-styrene block copolymer	SEPS
Styrene-isoprene-styrene block copolymer	SIS
Styrene-maleic anhydride plastics+impact resistant polystyrene	SMA+IPS
Styrene-maleic anhydride plastics	S/MA
Styrene-rubber plastics	SRP
Tetrafluoroethylene	TFE
Tetraoctyl pyromellitate (tetra-2-ethylhexyl pyromellitate)	TOPM
Thermoplastic elastomer	TPE
Thermoplastic elastomer, ether-ester	TEEE
Thermoplastic elastomer, fully crosslinked elastomer alloy	FCEA
Thermoplastic elastomer, highly crosslinked thermoplastic vulcanizate	HCTPV
Thermoplastic elastomer, olefinic	TEO
Thermoplastic elastomer, polyether block amide	PEBA
Thermoplastic elastomer, styrenic	TES
Thermoplastic elastomer styrenic, saturated	TESS
Thermoplastic elastomer styrenic, unsaturated	TESU
Thermoplastic elastomer-chlorinated ethylene alloy	TECEA
Thermoplastic polyester	TPES
Thermoplastic polyester:	
Copolyester [poly(aryl terephthalate)]	ARP
Polyarylate [poly(aryl terephthalate)]—liquid crystal polymer	PAT
Thermoplastic polyurethane	TPU
Thermoplastic polyurethane, reinforced	RTPU
Thermoset polyurethane	TSPU
Triallyl cyanurate	TAC
Trichlorethyl phosphate	TCEF
Tricresyl phosphate (or tritolyl phosphate)	TCF
Triheptyl trimellitate	THTM
Triisooctyl trimellitate	TIOTM
Trioctyl phosphate	TOF
Trioctyl trimellitate (tri-2-ethylhexyl trimellitate)	TOTM
Triphenyl phosphate	TPP
Trixylyl phosphate	TXF
Ultra-high molecular weight polyethylene	UHMWPE
Unsaturated polyester	UP
Urea-formaldehyde resin	UF
Vinyl chloride-ethylene resin	VCE
Vinyl chloride-ethylene-methyl acrylate resin	VCEMA
Vinyl chloride-ethylene-vinyl acetate resin	VCEVAC
Vinyl chloride-methyl acrylate resin	VCMA
Vinyl chloride-methyl methacrylate resin	VCMMA
Vinyl chloride-octyl acrylate resin	VCOA
Vinyl chloride-vinyl acetate resin	VCVAC
Vinyl chloride-vinylidene chloride resin	VCVDC
Vinylidene fluoride	VDF

6. Full List by Abbreviated Term

Abbreviated Term	Term
AB	Acrylonitrile/butadiene plastics
ABA	Acrylonitrile-butadiene-acrylate plastics
ABA+PC	Acrylonitrile-butadiene-acrylate+polycarbonate
ABA+PMMA	Acrylonitrile-butadiene-acrylate+poly(methyl methacrylate)
ABA+PVC	Acrylonitrile-butadiene-acrylate+poly(vinyl chloride)
ABS	Acrylonitrile-butadiene-styrene plastics
ABS+PA	Acrylonitrile-butadiene-styrene plastics+polyamide
ABS+PC	Acrylonitrile-butadiene-styrene plastics+polycarbonate
ABS+PPSU	Acrylonitrile-butadiene-styrene+polyphenylene sulfone
ABS+PTFE	Acrylonitrile-butadiene-styrene+polytetrafluoroethylene
ABS+PVC	Acrylonitrile-butadiene-styrene+poly(vinyl chloride)
ABS+SMA	Acrylonitrile-butadiene-styrene+styrene maleic anhydride
ABS+TPU	Acrylonitrile-butadiene-styrene+thermoplastic polyurethane
ACPES	Acrylonitrile-chlorinated polyethylene-styrene plastics
ADC	Allyl diglycol carbonate
AEPDMS	Acrylonitrile/ethylene-propylene-diene/styrene plastics
AES	Acrylonitrile-ethylene-styrene plastics
AMMA	Acrylonitrile-methyl methacrylate plastics
ARP	Aromatic polyester
AHP	Thermoplastic polyester, (polyaryl terephthalate)
ASA	Acrylonitrile-styrene-acrylate plastics
ASA+PC	Acrylonitrile-styrene-acrylate plastics+polycarbonate
ASA+PMMA	Acrylonitrile-styrene-acrylate+poly(methyl methacrylate)
ASA+PVC	Acrylonitrile-styrene-acrylate+poly(vinyl chloride)
ASE	Alkylsulfonic acid ester
BBP	Benzyl butyl phthalate
BOA	Benzyl octyl adipate (benzyl 2-ethylhexyl adipate)
BOP	Benzyl octyl phthalate (benzyl 2-ethylhexyl phthalate)
CA	Cellulose acetate
CAB	Cellulose acetate-butyrate
CAP	Cellulose acetate-propionate
CE	Cellulose plastics, general
CEF	Cellulose formaldehyde
CF	Cresol-formaldehyde resin
CMC	Carboxymethyl cellulose
CN	Cellulose nitrate
CP	Cellulose propionate
CPE	Chlorinated polyethylene
CPVC	Chlorinated poly(vinyl chloride)
CS	Casein
CSF	Caseine-formaldehyde resin
CTA	Cellulose triacetate
CTFE	Chlorotrifluoroethylene
DAC	Diallyl chlorendate (diallyl ester of 1,4,5,6,7,7-hexachlorobicyclo-(2,2,1)-5-heptene-2,3-dicarboxylic acid)
DAF	Diallyl fumarate
DAIP	Diallyl isophthalate
DAM	Diallyl maleate
DAP	Diallyl phthalate (diallyl orthophthalate)
DBP	Dibutyl phthalate
DBS	Dibutyl sebacate
DCHP	Dicyclohexyl phthalate
DCP	Dicapryl phthalate
DDP	Didecyl phthalate
DEP	Diethyl phthalate
DHP	Diheptyl phthalate
DHXP	Dihexyl phthalate
DIBP	Diisobutyl phthalate
DIDA	Diisodecyl adipate
DIDP	Diisodecyl phthalate

Copyright by the ASTM International
Wed Feb 02 01:47:36 2005

Abbreviated Term	Term
DIHP	Diisoheptyl phthalate
DIHXP	Diisohexyl phthalate
DINA	Diisononyl adipate
DINP	Diisononyl phthalate
DIOA	Diisooctyl adipate
DIOP	Diisooctyl phthalate
DIPP	Diisopentyl phthalate
DITDP	Diisotridecyl phthalate
DNOP	Di-n-octyl phthalate
DNP	Dinonyl phthalate
DOA	Dioctyl adipate (di-2-ethylhexyl adipate)
DOIP	Dioctyl isophthalate (di-2-ethylhexyl isophthalate)
DOP	Dioctyl phthalate (di-2-ethylhexyl phthalate)
DOS	Dioctyl sebacate (di-2-ethylhexyl sebacate)
DOTP	Dioctyl terephthalate (di-2-ethylhexyl terephthalate)
DOZ	Dioctyl azelate (di-2-ethylhexyl azelate)
DPCF	Diphenyl cresyl phosphate
DPOF	Diphenyl 2-ethylhexyl phosphate
DPOF	Diphenyl octyl phosphate
DUP	Diundecyl phthalate
EC	Ethyl cellulose
E-CTFE	Ethylene-chlorotrifluoroethylene copolymer
EEA	Ethylene-ethyl acrylate plastics
ELO	Epoxidized linseed oil
EMA	Ethylene-methacrylic acid plastics
EP	Epoxy, epoxide
EPD	Ethylene-propylene-diene plastics
EPM	Ethylene-propylene polymer
ESO	Epoxidized soya bean oil
ETFE	Ethylene-tetrafluoroethylene copolymer
EVA	Ethylene-vinyl acetate plastics
EVOH	Ethylene-vinyl alcohol copolymer
FCEA	Thermoplastic elastomer, fully crosslinked elastomer alloy
FEP	Perfluoro(ethylene-propylene) copolymer
FF	Furan-formaldehyde resin
GP	General purpose
HCTPV	Thermoplastic elastomer, highly crosslinked thermoplastic vulcanizate
HDPE	High-density polyethylene plastics
HIPS	High impact-resistant polystyrene
HNUA	Heptyl nonyl undecyl adipate
HNUP	Heptyl nonyl undecyl phthalate
HXODA	Hexyl octyl decyl adipate
HXODP	Hexyl octyl decyl phthalate
IPS	Impact-resistant polystyrene
LCP	Liquid crystal polymer
LDPE	Low density polyethylene plastics
LLDPE	Linear low density polyethylene plastics
LMDPE	Linear medium density polyethylene plastics
MBS	Methacrylate-butadiene-styrene plastics
MC	Methyl cellulose
MDPE	Medium density polyethylene plastics
MF	Melamine-formaldehyde resin
MFA	Perfluoromethoxy resin
MMA	Methyl methacrylate
MMABS	Methyl methacrylate-acrylonitrile-butadiene-styrene resin
MPA	Fluorocarbon perfluoromethoxy
MPF	Melamine/phenol-formaldehyde resin
NUA	Nonyl undecyl adipate
NUP	Nonyl undecyl phthalate
ODA	Octyl decyl adipate
ODP	Octyl decyl phthalate
ODTM	*n*-Octyl decyl trimellitate
PA	Polyamide (nylon)
PA	Nylon (see also polyamide)
PA11	Polyamide 11
PA12	Polyamide 12
PA1212	Polyamide 1212
PA46	Polyamide 46
PA6	Polyamide 6
PA610	Polyamide 610
PA612	Polyamide 612
PA66	Polyamide 66
PA69	Polyamide 69
PA+	Polyamide (amorphous) blend
PA+EMA	Polyamide plastics+ethylene-methacrylic acid (ionomer)
PA+PE	Polyamide+polyethylene
PA+PPE	Polyamide+poly(phenylene ether)
PA+RBR	Polyamide+rubber
PA+SAN	Polyamide+styrene-acrylonitrile
PAA	Poly(acrylic acid)
PADC	Poly(allyl diglycol carbonate)
PAE	Polyarylether ketone)
PAI	Polyamide-imide
PAK	Polyester alkyd (or polyacrylate)
PAN	Polyacrylonitrile
PAR	Polyarylate
PARA	Polyaryl amide
PASU	Polyarylsulfone
PAT	Polyester, thermoplastic; polyarylate [poly(aryl terephthalate)]
PAUR	Poly(ester urethane)
PB	Polybutene-1
PBA	Poly(butyl acrylate)
PBAN	Polybutadiene-acrylonitrile
PBS	Polybutadiene-styrene
PBT	Poly(butylene terephthalate)
PBT+PET[6]	Poly(butylene terephthalate)+poly(ethylene terephthalate)
PBT+PPE	Poly(butylene terephthalate)+poly(phenylene ether)
PBT+RBR	Poly(butylene terephthalate)+rubber
PC	Polycarbonate
PC+PBT	Polycarbonate+poly(butylene terephthalate)
PC+PE	Polycarbonate+polyethylene
PC+PET[6]	Polycarbonate+poly(ethylene terephthalate)
PC+SMA	Polycarbonate+styrene-maleic anhydride
PC+TPU	Polycarbonate+thermoplastic polyurethane
PCCE	Poly(cyclohexylenedimethylene cyclohexandicarboxylate), glycol and acid comonomer
PCL	Poly(ε-caprolactone)
PCT	Poly(cyclohexylenedimethylene terephthalate)
PCTA	Poly(cyclohexylenedimethylene terephthalate), cid comonomer
PCTFE	Polychlorotrifluoroethylene
PCTG	Poly(cyclohexylenedimethylene terephthalate), glycol
PDAP	Poly(diallyl phthalate)
PE	Polyethylene
PEBA	Thermoplastic elastomer, polyether block amide
PEBA	Poly(ether block amide)
PEEK	Polyetheretherketone
PEEKK	Polyetheretherketoneketone
PEI	Polyetherimide
PEK	Polyetherketone
PEKEKK	Polyetherketonetherketoneketone
PEKK	Polyetherketoneketone
PEN	Poly(ethylene naphthalate)
PEOX	Poly(ethylene oxide)
PES	Poly(ether sulfone)
PET[6]	Poly(ethylene terephthalate)
PET[6]+PMMA	Poly(ethylene terephthalate)+poly(methyl methacrylate)
PET[6]+PPSU	Poly(ethylene terephthalate)+poly(phenylene sulfone)
PET[6]+RBR	Poly(ethylene terephthalate)+rubber
PETG	Poly(ethylene terephthalate) glycol comonomer
PEUR	Poly(ether urethane)
PF	Phenol-formaldehyde resin
PFA	Perfluoro(alkoxy alkane)
PFF	Phenol-furfural resin
PHB	Polyhydroxy butyrate
PHBV	Polyhydroxy butyrate-polyhydroxy valerate
PI	Polyimide
PIB	Polyisobutylene
PIR	Polyisocyanurate
PISU	Polyimidesulfone
PK	Polyketone

Abbreviated Term	Term
PMCA	Poly(methyl-α-chloroacrylate)
PMI	Polymethacrylimide
PMMA	Poly(methyl methacrylate)
PMMI	Poly(methyl methacrylimide)
PMP	Poly-4-methylpentene-1
PMS	Poly-α-methylstyrene
POB	Poly-p-oxybenzoate
POM	Polyoxymethylene, polyacetal
POM+PTFE	Polyoxymethylene+polytetrafluoroethylene
POM+RBR	Polyoxymethylene+rubber
PP	Polypropylene
PPA	Polyphthalamide
PPE	Poly(phenylene ether) (or poly(phenylene oxide), a deprecated term)
PPE+IPS	Poly(phenylene ether)+impact-resistant polystyrene
PPOX	Poly(propylene oxide)
PPS	Poly(phenylene sulfide)
PPSU	Poly(phenyl sulfone)
PPS+PTFE	Poly(phenylene sulfide)+polytetrafluoroethylene
PS	Polystyrene
PSU	Polysulfone
PTFE	Polytetrafluorethylene
PUR	Polyurethane
PUR+PIR	Polyurethane+polyisocyanate
PVAC	Poly(vinyl acetate)
PVOH	Poly(vinyl alcohol)
PVB	Poly(vinyl butyral)
PVC	Poly(vinyl chloride)
PVC+CPE	Poly(vinyl chloride)+chlorinated polyethylene
PVC+NBR	Poly(vinyl chloride)+nitrile-butadiene rubber
PVC+PMMA	Poly(vinyl chloride)+poly(methyl methacrylate)
PVC+PUR	Poly(vinyl chloride) plastics+polyurethane
PVCA	Poly(vinyl chloride-acetate)
PVDC	Poly(vinylidene chloride)
PVDF	Poly(vinylidene fluoride)
PVF	Poly(vinyl fluoride)
PVFM	Poly(vinyl formal)
PVK	Poly(vinyl carbazole)
PVP	Poly(vinyl pyrrolidone)
RTPU	Thermoplastic polyurethane, reinforced
S/MA	Styrene-maleic anhydride plastics
SAN	Styrene-acrylonitrile plastic
SB	Styrene-butadiene plastics
SBS	Styrene-butadiene-styrene block copolymer
SEBS	Styrene-ethylene/butylene-styrene block copolymer
SEPS	Styrene-ethylene/propylene-styrene block copolymer
SI	Silicone plastics
SIS	Styrene-isoprene-styrene block copolymer
SMA+IPS	Styrene-maleic anhydride+impact-resistant polystyrene
SMS	Styrene-α-methylstyrene plastic
SP	Saturated polyester plastic
SRP	Styrene-rubber plastics
SS	Single stage
TAC	Triallyl cyanurate
TCEF	Trichloroethyl phosphate
TCF	Tricresyl phosphate (or tritolyl phosphate)
TECEA	Thermoplastic elastomer-chlorinated ethylene alloy
TEEE	Thermoplastic elastomer, ether-ester
TEO	Thermoplastic elastomer, olefinic
TES	Thermoplastic elastomer, styrenic
TESS	Thermoplastic elastomer styrenic, saturated
TESU	Thermoplastic elastomer styrenic, unsaturated
TFE	Tetrafluoroethylene
THTM	Triheptyl trimellitate
TIOTM	Triisooctyl trimellitate
TOF	Trioctyl phosphate
TOPM	Tetraoctyl pyromellitate (tetra-2-ethylhexyl pyromellitate)
TOTM	Trioctyl trimellitate (tri-2-ethylhexyl trimellitate)
TPE	Thermoplastic elastomer
TPES	Thermoplastic polyester
TPP	Triphenyl phosphate
TPU	Thermoplastic polyurethane
TSPU	Thermoset polyurethane
TXF	Trixylyl phosphate
UF	Urea-formaldehyde resin
UHMWPE	Ultra-high molecular weight polyethylene
UP	Unsaturated polyester
VCE	Vinyl chloride-ethylene resin
VCEMA	Vinyl chloride-ethylene-methyl acrylate resin
VCEVAC	Vinyl chloride-ethylene-vinyl acetate resin
VCMA	Vinyl chloride-methyl acrylate resin
VCMMA	Vinyl chloride-methyl methacrylate resin
VCOA	Vinyl chloride-octyl acrylate resin
VCVAC	Vinyl chloride-vinyl acetate resin
VCVDC	Vinyl chloride-vinylidene chloride resin
VDF	Vinylidene fluoride

7. Code Numbers for Identifying Flame Retardant Compounds

7.1 The code numbers are grouped according to the chemical composition of the flame retardant.

7.1.1 *Halogenated Compounds*:

7.1.1.1 In compounds containing both aliphatic/alicyclic and aromatic groups, the group containing the halogen determines the code to be used.

Code	Compound
10	aliphatic/alicyclic chlorinated compounds
11	aliphatic/alicyclic chlorinated compounds in combination with antimony compounds
12	aromatic chlorinated compounds
13	aromatic chlorinated compounds in combination with antimony compounds
14	aliphatic/alicyclic brominated compounds
15	aliphatic/alicyclic brominated compounds in combination with antimony compounds
16	aromatic brominated compounds (excluding brominated diphenylether and biphenyls)
17	aromatic brominated compounds (excluding brominated diphenylether and biphenyls) in combination with antimony compounds
18	polybrominated diphenylether
19	polybrominated diphenylether in combination with antimony compounds
20	polybrominated biphenyls
21	polybrominated biphenyls in combination with antimony compounds
22 to 24	not allocated
25	aliphatic fluorinated compounds
26 to 29	not allocated

7.2 *Nitrogen Compounds*:

Code	Compound
30	nitrogen compounds (including but not limited to melamine, melamine cyanurate, urea)
31 to 39	not allocated

7.3 *Organic Phosphorus Compounds*:

Code	Compound
40	halogen free organic phosphorous compounds
41	chlorinated organic phosphorus compounds
42	brominated organic phosphorus compounds
43 to 49	not allocated

7.4 *Inorganic Phosphorus Compounds*:

Code	Compound
50	ammonium orthophosphates
51	ammonium polyphosphates
52	red phosphorus
53 to 59	not allocated

7.5 *Metallic Oxides, Hydroxides, and Salts*:

Code	Compound

Copyright by the ASTM International
Wed Feb 02 01:47:37 2005

60	aluminum hydroxide
61	magnesium hydroxide
62	antimony (III)-oxide
63	alkali antimonate
64	magnesium/calcium carbonate-hydrate
65 to 69	not allocated

7.6 *Boron and Zinc Compounds*:

Code	Compound
70	inorganic boron compounds (excluding zinc borate)
71	organic boron compounds
72	zinc borate
73	inorganic zinc compounds (excluding zinc borate)
74	not allocated

7.7 *Silica Compounds*:

Code	Compound
75	inorganic silica compounds
76	organic silica compounds
77 to 79	not allocated

7.8 *Miscellaneous Compounds*:

Code	Compound
80	graphite
81 to 89	not allocated
90 to 99	not allocated

8. Use of Abbreviated Terms

8.1 When abbreviated terms are used in publications or other written matter, their first occurrence in the text should be enclosed in parentheses and preceded by the written word or words being abbreviated. Subsequent references to such words in the article can then be made using the abbreviated term. For example, if one wishes to use PET[6] as the acronym for poly(ethylene terephthalate), wording such as the following would be acceptable: "Poly(ethylene terephthalate) (PET[6]) is a crystalline plastic. PET[6] offers many advantages in such articles as soft drink bottles."

8.2 Additional information on use of abbreviated terms, symbols and codes for flame retardants is included in Guide D 1972.

9. Keywords

9.1 abbreviated terms; code numbers; flame retardants; monomers; plastic blends and alloys; plastics; plasticizers; terminology symbols

APPENDIX

(Nonmandatory Information)

X1. A SUGGESTED SYSTEM FOR PREPARING ABBREVIATED TERMS FOR PLASTICS AND RELATED TERMS[6]

NOTE X1.1—The use of the following guide in establishing abbreviated terms for plastics and related terms will promote uniform and systematic standardization.[7]

X1.1 Use upper case letters for the main components in the order in which they occur in the plastics term for which an abbreviated term is being established, for example:

Poly(vinyl chloride) = PVC

X1.2 Use generic terms for family designations, for example:

nylon for polyamide plastics

X1.3 Use figures and letters to distinguish among plastics prepared from various condensation units in a homologous series, for example:

Poly(hexamethylene sebacamide) = PA 610 where, with aliphatic components, the first number(s) refers to the number of carbon atoms in the diamine and the second number(s) refers to the number of carbon atoms in the diacid. It is the convention not to use any separator, such as a comma, dash, or virgule (solidus,/) between the numbers. In these systems there is no confusion when the separator is not used. With alicyclic or aromatic diamines or diacids, a letter acronym is usually used. For example:

meta−phenylene diamine = MPD

terephthalic acid = T

isophthalic acid = I

X1.4 The components in copolymers are separated by hyphens "-" in the term, but usually no separation is required in the abbreviated term. In cases where use of the hyphen may cause confusion, it is acceptable to use a virgule, "/", as the separator. The virgule also is correctly termed a solidus and often, incorrectly, referred to as a "slash" or "diagonal."

X1.5 The components in blends of polymers are separated by a plus sign, "+", in both the term and the abbreviated term.

X1.6 A more elaborate system for developing abbreviated terms for plastics and related materials has been standardized by ISO in ISO 1043.

[7] Based in part on Proposals under Consideration by the Division of Plastics and High Polymers, IUPAC.

SUMMARY OF CHANGES

Committee D-20 has identified the location of selected changes to this terminology since the last issue that may impact the use of this terminology.

D 1600 – 97:
(*1*) The scope was expanded with a new part to provide for inclusion of symbols and codes for flame retardant additives in plastics.
(*2*) An ISO equivalence statement was added to the scope.
(*3*) In Section 2, the list of referenced documents was expanded as needed to conform to the other changes.
(*4*) A definition for "flame retardant" from ISO 472 was included in Section 2.
(*5*) Section 7 was renumbered to Section 8, retitled, and additional information was added to provide reference to the standard that provides instructions for marking plastics products so that the new code numbers can be implemented.
(*6*) A new Section 7 was added to add codes numbers for different classes of flame retardants.
(*7*) Keywords were added in a new Section 9.
D 1600 – 98:
(*1*) Poly(ethylene naphthalate) (PEN) and perfluoromethoxy resin (MFA) were added.
D 1600 – 99:
(*1*) Added PCL.
(*2*) E-CTFE, FCEA, HCTPV, MPA, PPSU, and VDF added editorially.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: D 2000 – 01

Approved by
Society of Automotive Engineers
SAE Recommended Practice J200

Standard Classification System for Rubber Products in Automotive Applications[1]

This standard is issued under the fixed designation D 2000; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This specification has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This classification system tabulates the properties of vulcanized rubber materials (natural rubber, reclaimed rubber, synthetic rubbers, alone or in combination) that are intended for, but not limited to, use in rubber products for automotive applications.

NOTE 1—This classification system may serve many of the needs of other industries in much the same manner as SAE numbered steels. It must be remembered, however, that this system is subject to revision when required by automotive needs. It is recommended that the latest revision always be used.

1.2 This classification system is based on the premise that the properties of all rubber products can be arranged into characteristic material designations. These designations are determined by *types,* based on resistance to heat aging, and *classes,* based on resistance to swelling in oil. Basic levels are thus established which, together with values describing additional requirements, permit complete description of the quality of all elastomeric materials.

1.3 In all cases where the provisions of this classification system would conflict with those of the detailed specifications for a particular product, the latter shall take precedence.

NOTE 2—When the rubber product is to be used for purposes where the requirements are too specific to be completely prescribed by this classification system, it is necessary for the purchaser to consult the supplier in advance, to establish the appropriate properties, test methods, and specification test limits.

1.4 The values stated in SI units are to be regarded as the standard.

2. Referenced Documents

2.1 *ASTM Standards:*

D 395 Test Methods for Rubber Property—Compression Set[2]

D 412 Test Methods for Vulcanized Rubber and Thermoplastic Rubbers and Thermoplastic Elastomers—Tension[2]

D 429 Test Methods for Rubber Property—Adhesion to Rigid Substrates[2]

D 430 Test Methods for Rubber Deterioration—Dynamic Fatigue[2]

D 471 Test Method for Rubber Property—Effect of Liquids[2]

D 573 Test Method for Rubber—Deterioration in an Air Oven[2]

D 575 Test Methods for Rubber Properties in Compression[2]

D 624 Test Method for Tear Strength of Conventional Vulcanized Rubber and Thermoplastic Elastomers[2]

D 865 Test Method for Rubber—Deterioration by Heating in Air (Test Tube Enclosure)[2]

D 925 Test Methods for Rubber Property—Staining of Surfaces (Contact, Migration, and Diffusion)[2]

D 945 Test Methods for Rubber Properties in Compression or Shear (Mechanical Oscillograph)[2]

D 1053 Test Methods for Rubber Property—Stiffening at Low Temperatures: Flexible Polymers and Coated Fabrics[2]

D 1171 Test Method for Rubber Deterioration—Surface Ozone Cracking Outdoors or Chamber (Triangular Specimens)[2]

D 1329 Test Method for Evaluating Rubber Property—Retraction at Lower Temperatures (TR Test)[2]

D 1349 Practice for Rubber—Standard Temperatures for Testing[2]

D 1418 Practice for Rubber and Rubber Latices—Nomenclature[2]

D 2137 Test Methods for Rubber Property—Brittleness Point of Flexible Polymers and Coated Fabrics[2]

D 2240 Test Method for Rubber Property—Durometer Hardness[2]

D 3183 Practice for Rubber—Preparation of Pieces for Test Purposes from Products[2]

D 5964 Practice for Rubber—IRM 902 and IRM 903 Replacement Oils for ASTM No. 2 and ASTM No. 3 Oils[2]

3. Purpose

3.1 The purpose of this classification system is to provide guidance to the engineer in the selection of practical, commercially available rubber materials, and further to provide a method for specifying these materials by the use of a simple

[1] This classification system is under the jurisdiction of ASTM Committee D11 on Rubber and is the direct responsibility of Subcommittee D11.30 on Classification of Rubber Compounds .

Current edition approved July 10, 2001. Published September 2001. Originally published as D 2000 – 62 T. Last previous edition D 2000 – 00.

Wed Feb 02 01:48:12 2005

"line call-out" designation.

3.2 This classification system was developed to permit the addition of descriptive values for future rubber materials without complete reorganization of the classification system and to facilitate the incorporation of future new test methods to keep pace with changing industry requirements.

4. Type and Class

4.1 The prefix letter "M" shall be used to indicate that the classification system is based on SI units.

NOTE 3—Call outs not prefixed by the letter M refer to an earlier classification system based on inch-pound units. This was published in editions up to 1980.

4.2 Rubber materials shall be designated on the basis of *type* (heat resistance) and *class* (oil resistance). Type and class are indicated by letter designations as shown in Table 1 and Table 2 and illustrated in 9.1.

4.3 *Type* is based on changes in tensile strength of not more than ±30 %, elongation of not more than – 50 %, and hardness of not more than ±15 points after heat aging for 70 h at an appropriate temperature. The temperatures at which these materials shall be tested for determining type are listed in Table 1.

4.4 *Class* is based on the resistance of the material to swelling in ASTM Oil No. 3 after 70-h immersion at a temperature determined from Table 1, except that a maximum temperature of 150°C (the upper limit of oil stability) shall be used. Limits of swelling for each class are shown in Table 2.

4.4.1 ASTM No. 2 and No. 3 Oils have been replaced by IRM 902 and 903 Oils, respectively, under Practice D 5964. These Oils are similar but not identical to ASTM No. 2 and No. 3 Oils.

4.4.2 Substitutability of IRM 902 and 903 Oils for ASTM No. 2 and No. 3 Oils has not been established, as their swelling characteristics are different and may affect compound classification.

NOTE 4—The selection of type based on heat resistance is understood to be indicative of the inherent heat resistance that can be normally expected from commercial compositions. Likewise, choice of class is based on the range of volume swell normally expected from such commercial compositions as established by type. *The fact that a type and class of material is listed in Table 6, under Basic Requirements, indicates that materials that meet these requirements for heat and oil resistance are commercially available.*

4.5 The letter designations shall always be followed by a three-digit number to specify the hardness and the tensile strength—for example, 505. The first digit indicates durometer hardness, Type A, for example, 5 for 50 ± 5, 6 for 60 ± 5. The next two digits indicate the minimum tensile strength—for example, 05 for 5 MPa, 14 for 14 MPa. *Correlation of*

available materials for desired hardness and tensile strength is obtained through the elongation values in Table 6. See 7.2.

5. Grade Numbers, Suffix Letters, and Number

5.1 *Grade Numbers*—Since the basic requirements do not always describe sufficiently all the necessary qualities, provision is made for deviation or adding requirements through a system of prefix grade numbers. Grade No. 1 indicates that only the basic requirements are compulsory, and no suffix requirements are permitted. Grades other than No. 1 are used for expressing deviation or additional requirements and are listed as "Available Suffix Grade Numbers" in the last column under Basic Requirements in Table 6. A grade number is written as a material prefix number preceding the letters for type and class (see 9.1). Grade No. 1 is always an available suffix grade number, and thus is not referenced in the last column of each basic requirement table.

5.2 *Suffix Letters*—The suffix letters that may be used, together with their meaning, appear in Table 3.

5.3 *Suffix Numbers*—Each suffix letter should preferably be followed by two suffix numbers (see Note 6 in 8.1). *The first suffix number always indicates the test method;* time of test is part of the method and is taken from the listings in Table 5. *The second suffix number, if used, always indicates the temperature of test* and is taken from Table 4. Where three-digit numbers are required, they are separated by a dash—for example: –10; B4–10; F1–11.

6. Composition and Manufacture

6.1 This classification system is predicated upon materials furnished under a specification based thereon being manufactured from natural rubber, reclaimed rubber, synthetic rubber, alone or in combination, together with added compounding ingredients of such nature and quantity as to produce vulcanizates that comply with the specified requirements. All materials and workmanship shall be in accordance with good commercial practice, and the resulting product shall be free of porous areas, weak sections, bubbles, foreign matter, or other defects affecting serviceability.

6.2 *Color*—With the exception of FC, FE, FK, and GE materials, the values in the material tables are based on black compounds and comparable values may not be available in color.

7. Basic Requirements

7.1 The basic requirements for physical properties specified in Table 6[3] are based on values obtained from standard laboratory test specimens prepared and tested in accordance with the applicable ASTM test methods. *Test results from specimens prepared from finished products may not duplicate values obtained from standard test specimens.*

NOTE 5—When standard test specimens are cut from finished parts in accordance with Practice D 3183, a deviation to the extent of 10 % (on tensile strength and elongation values only) is permissible when agreed upon by the purchaser and the supplier. This deviation is permissible *only* because of the recognized effects of knitting, grain, and buffing on the material when test specimens are prepared from finished parts and tested for tensile strength and elongation. When differences due to the method of processing or to the difficulty in obtaining suitable test specimens from the finished part arise, the purchaser and the supplier may agree on acceptable deviations. This can be done by comparing results of standard test specimens with those obtained on actual parts.

7.2 The available materials are listed in the appropriate material section of the table, giving each hardness and tensile strength with its appropriate elongation value. Also, there is a repetition of the values for the basic heat and oil aging requirements for the material resulting from the assignment of type and class. In addition, values for compression set, normally a basic requirement to ensure proper vulcanization, are specified.

8. Suffix Requirements

8.1 Suffix requirements shall be specified *only as needed* to define qualities necessary to meet service requirements. These suffix requirements are set forth for the various grade numbers. Suffix letters and suffix numbers describing these suffix requirements may be used singly or in combination, *but not all suffix values available for a given material need be specified.*

NOTE 6—Examples of the use of suffix letters and numbers would be A14 and EO34. Suffix A (Table 3) stands for heat resistance, Suffix 1 (Table 5) specifies that the test be run in accordance with Test Method D 573 for 70 h, and Suffix A (Table 4) indicates the temperature of test as 100°C. Similarly, Suffix EO34 indicates resistance in ASTM Oil No. 3 in accordance with Test Method D 471 for 70 h at 100°C.[4]

8.2 Basic requirements are always in effect, unless superseded by specific suffix requirements in the "line call-out."

[3] Tensile values are shown as pounds per square inch in Table 6 for information only.

[4] ASTM Oil No. 3 is no longer commercially available. It has been replaced by IRM903 oil. See 4.4.1.

[A] Use ozone chamber exposure method of Test Method D 1171, Method A.

[B] Test Method D 1171, Weather Test, is 6 weeks duration. Test area and time of year to be agreed upon by the purchaser and the manufacturer

[C] Use ozone chamber exposure method of Test Method D 1171, Method B.

[D] ASTM No. 2 and No. 3 Oils are no longer commercially available. They have been replaced by IRM 902 and 903 Oils, respectively. See 4.4.1. ASTM Oil No. 1, IRM 902 and IRM 903 may be ordered from Penreco, 4426 East Washington Blvd., Los Angeles, CA 90023-4476. They are also distributed by R. E. Carroll, Inc., P.O. Box 5806, Trenton, NJ 08638-0806.

[E] Distilled water shall be used. Volume increase by water displacement method, except alcohol dip omitted. When determining changes in tensile strength, elongation, and hardness, test tube to be ¾full after specimens are immersed. Determination to be made after 30 min. Cool in distilled water, acetone dip to be omitted.

[F] Equal parts by volume of distilled water and reagent grade ethylene glycol. Volume increase by displacement method, except alcohol dip omitted, When determining changes in tensile strength, elongation, and hardness, test tube to be ¾ full after specimens are immersed. Determination to be made after 30 min. Cool in distilled water, acetone dip to be omitted.

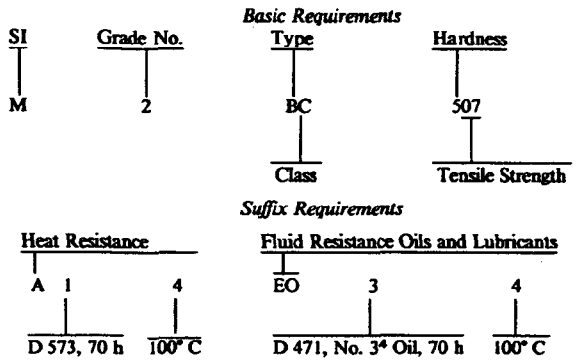
[G] Test method to be specified.

Copyright by the ASTM International
Wed Feb 02 01:48:23 2005

9. Line Call-Outs

9.1 A "line call-out," *which is a specification,* shall contain: the documents names, the prefix letter M, the grade number, the material designation (type and class), and the hardness and tensile strength, followed by the appropriate suffix requirements. Following is an example of a "line call-out" or specification:

ASTM D 2000 M2BC 507 A14EO34



In this example, basic requirements for heat resistance and fluid resistance are superseded by suffix requirements. However, the basic requirement of 80 % for compression set, which is not included as a suffix requirement, is not superseded and therefore shall be met as specified in Table 6.

10. Test Methods

10.1 The applicable test methods are listed in Table 5.

11. Sampling and Inspection

11.1 A lot, unless otherwise specified, shall consist of all products of the same material submitted for inspection at the same time.

11.2 When proof of conformance with a specification based on this classification system is required, the supplier shall, upon request of the purchaser at the time of ordering, furnish a sufficient number of samples to permit the performance of the required tests. Test specimens shall be prepared as prescribed in 7.1. The samples shall be warranted to have equivalent cure and to be from the same run or batch of compound used in the lot.

ANNEX

(Mandatory Information)

A1. Statement of Understanding between SAE CARS and ASTM D11.30

A1.1 The SAE Committee on Automotive Rubber Specifications, (CARS), and the ASTM D11.30 committee affirm that we will work together to maintain the SAE J200 and ASTM D 2000 specification systems. It is our goal to keep the tables in these two documents equivalent. As such, the SAE CARS will be the gatekeeper of any changes and additions to the tables in these specification systems. They will consider, as necessary, the expansion of current tables or the addition of new tables based on new rubber materials that will better serve both the rubber industry and their customers. SAE CARS may ask for assistance from ASTM D11.30 to provide the necessary laboratories for performing the required interlaboratory testing. In the unlikely event that SAE CARS declines to make any additions or changes to the tables, then ASTM D11.30 may choose to proceed with making those changes or additions if they deem them as additive for the rubber industry.

APPENDIX

(Nonmandatory Information)

X1. TYPE AND CLASS OF POLYMER USAGE

X1.1 This appendix is intended to assist the users of Classification System D 2000-SAE J200 and is not to be considered as part of the system. Table X1.1 lists the Classification System D 2000-SAE J200 material designations (type and class) and the type of polymer most often used in meeting the material requirements (type and class). This table is not intended to be limiting; other polymers may be used to meet the same specification.

TABLE X1.1 Polymers Most Often Used in Meeting Material Requirements

Classification System D2000-SAE J200 Material Designation (Type and Class)	Type of Polymer Most Often Used[A]
AA	Natural rubber, reclaimed rubber, SBR, butyl, EP polybutadiene, polyisoprene
AK	Polysulfides
BA	Ethylene propylene, high-temperature SBR and butyl compounds
BC	Chloroprene polymers (neoprene), cm
BE	Chloroprene polymers (neoprene), cm
BF	NBR polymers
BG	NBR polymers, urethanes
BK	NBR
CA	Ethylene propylene
CE	Chlorosulfonated polyethylene (Hypalon), cm
CH	NBR polymers, epichlorohydrin polymers
DA	Ethylene propylene polymers
DE	CM, CSM
DF	Polyacrylic (butyl-acrylate type)
DH	Polyacrylic polymers, HNBR
EE	AEM
EH	ACM
EK	FZ
FC	Silicones (high strength)
FE	Silicones
FK	Fluorinated silicones
GE	Silicones
HK	Fluorinated elastomers (Viton, Fluorel, etc.)
KK	Perfluoroelastomers

[A] Refer to Practice D 1418.

Standard Specification for Acrylonitrile-Butadiene-Styrene (ABS) Plastic Pipe (SDR-PR)[1]

This standard is issued under the fixed designation D 2282; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers acrylonitrile-butadienestyrene (ABS) pipe produced by single extrusion or simultaneous multiple coextrusion, in standard thermoplastic pipe dimension ratios and pressure rated for water (see Appendix). Included are criteria for classifying ABS plastic pipe materials and ABS plastic pipe, a system of nomenclature for ABS plastic pipe, and requirements and test methods for materials, workmanship, dimensions, sustained pressure, burst pressure, and extrusion quality. Methods of marking are also given.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 1—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious saftey hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 7, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 General—Definitions are in accordance with Terminology F 412. Abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for acrylonitrile-butadiene-styrene plastic is ABS.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *acrylonitrile-butadiene-styrene (ABS) pipe and fitting plastics*—plastics containing polymers or blends of polymers, or both, in which the minimum butadiene content is 6 %, the minimum acrylonitrile content is 15 %, the minimum styrene or substituted styrene content, or both, is 15 %, and the

maximum content of all other monomers is not more than 5 %, and lubricants, stabilizers, and colorants.

3.2.2 *hydrostatic design stress*—the estimated maximum tensile stress the material is capable of withstanding continuously with a high degree of certainty that failure of the pipe will not occur. This stress is circumferential when internal hydrostatic water pressure is applied.

3.2.3 *pressure rating (PR)*—the estimated maximum water pressure the pipe is capable of withstanding continuously with a high degree of certainty that failure of the pipe will not occur.

3.2.4 *relation between standard dimension ratio, hydrostatic design stress, and pressure rating*—the following expression is used in this specification to relate standard dimension ratio, hydrostatic design stress, and pressure rating:

$$2S/P = R - 1 \text{ or } 2S/P = (D_O/t) - 1$$

where:

S = hydrostatic design stress, psi (or MPa),
P = pressure rating, psi (or MPa),
D_O = average outside diameter, in. (or mm),
t = minimum wall thickness, in. (or mm), and
R = standard thermoplastic pipe dimension ratio (D_O/t for ABS pipe), also known as SDR.

3.2.5 *standard thermoplastic pipe dimension ratio (SDR)*—the ratio of pipe diameter to wall thickness. For ABS pipe it is calculated by dividing the average outside diameter of the pipe in millimetres or in inches by the minimum wall thickness in millimetres or in inches. If the wall thickness calculated by this formula is less than 0.060 in. (1.52 mm), it shall be arbitrarily increased to 0.060 in. (1.52 mm). SDR values shall be rounded to the nearest 0.5.

3.2.6 *standard thermoplastic pipe materials designation code*—the pipe materials designation code shall consist of the abbreviation ABS for the type of plastic, followed by the ASTM type and grade (see Table X1.2), and the hydrostatic design stress in units of 100 psi with any decimal figures dropped. When the design stress code contains less than two figures, a cipher is used before the number. Thus a complete material code consists of three letters and four figures for ABS plastic pipe materials (see 4.3).

4. Materials

4.1 *General*—Acrylonitrile-butadiene-styrene plastics used to make pipe meeting the requirements of this specification are categorized by means of two criteria namely (*1*) short-term strength tests and (2) long-term strength tests.

4.2 *Basic Materials*—This specification covers ABS pipe made from three ABS plastics as defined in Specification D 3965, in which the requirements are based on short-term tests. These are ABS Classes 42222, 20643, and 30444.

4.3 *Hydrostatic Design Stress*—This specification covers ABS pipe made from ABS plastics as defined by four hydrostatic design stresses developed on the basis of long-term tests (Appendix X1.2).

4.4 *Compound*—The ABS plastic extrusion compound shall meet the requirements of ABS Classes 42222, 20643, or 30444 as described in Specification D 3965. For pipe produced by simultaneous multiple coextrusion, all layers shall be of the same formulation.

4.5 *Rework Material*—The manufacturers shall use only their own clean rework pipe material and the pipe produced shall meet all the requirements of this specification.

5. Pipe Classification

5.1 *General*—This specification covers ABS pipe produced by single extrusion or simultaneous multiple coextrusion from three ABS plastic pipe materials in four standard dimension ratios and six water pressure ratings for nonthreaded pipe. Pipe produced by simultaneous multiple coextrusion shall be classified as "CoeX."

5.2 *Standard Thermoplastic Pipe Dimension Ratios (SDR)*—This specification covers ABS pipe in four standard dimension ratios, namely, 13.5, 17, 21, and 26. These are referred to as SDR13.5, SDR17, SDR21, and SDR26, respectively. The pressure rating is uniform for all nominal pipe sizes for a given ABS pipe material and SDR (see Table X1.1, Appendix).

6. Requirements

6.1 *Workmanship*——The pipe shall be homogeneous throughout and free of visible cracks, holes, foreign inclusions, or other defects. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

6.2 *Dimensions and Tolerances*:

6.2.1 *Outside Diameters*—The outside diameters and tolerances shall be as shown in Table 1 when measured in accordance with 7.4 and 7.4.1.

6.2.2 *Wall Thickness*—The wall thicknesses and tolerances shall be as shown in Table 2 when measured in accordance with 7.4 and 7.4.2.

6.2.3 *Thickness of Outer Layer*—For pipe produced by simultaneous multiple extrusion, that is, pipe containing two or more concentric layers, the outer layer shall be at least 0.020 in. (0.50 mm) thick.

TABLE 1 Outside Diameters and Tolerances for ABS Plastic Pipe, in.

12	0.490	+0.059	0.606	+0.073	...	...	...	...

[A] The minimum is the lowest wall thickness of the pipe at any cross section. The maximum permitted wall thickness, at any cross section, is the minimum wall thickness plus the stated tolerance. All tolerances are on the plus side of the minimum requirement.

6.2.4 *Wall Thickness Range*—The wall thickness range shall be within 12 % when measured in accordance with 7.4 and 7.4.3.

6.3 *Bond*—For pipe produced by simultaneous multiple coextrusion, the bond between the layers shall be strong and uniform, it shall not be possible to separate any two layers with a probe or point of a knife blade so that the layers separate cleanly at any point, nor shall separation of bond occur, between layers, during testing performed under the requirements of this specification.

6.4 *Sustained Pressure*—The pipe shall not fail, balloon, burst, or weep as defined in Test Method D 1598 at the test pressures given in Table 3 when tested in accordance with 7.5.

6.5 *Burst Pressure*—The minimum burst pressures for ABS plastic pipe shall be as given in Table 4, when determined in accordance with 7.6.

7. Test Methods

7.1 *Conditioning*—Condition the test specimens at 73 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618 for those tests where conditioning is required.

TABLE 3 Sustained Pressure Test Conditions for Water at 73°F (23°C) for ABS Plastic Pipe

Standard Dimension Ratio	Pressure[A] Required for Test					
	ABS1316		ABS2112		ABS1208, ABS1210	
	psi	MPa	psi	MPa	psi	MPa
13.5	510	3.52	430	2.96	340	2.34
17	400	2.76	340	2.34	270	1.86
21	320	2.21	270	1.86	220	1.52
26	260	1.79	220	1.52	170	1.17

[A] The fiber stresses used to derive these test pressures are as follows:

ABS1316	3200 psi (22.1 MPa)
ABS2112	2700 psi (18.6 MPa)
ABS1208, ABS1210	2140 psi (14.8 MPa)

Some minor adjustments have been made to keep the test pressures uniform to simplify testing.

TABLE 4 Burst Pressure Requirements for Water at 73°F (23°C) for ABS Plastic Pipe

Standard Dimension Ratio	Min Burst Pressure[A]							
	ABS2112		ABS1316		ABS1210		ABS1208	
	psi	MPa	psi	MPa	psi	MPa	psi	MPa
13.5	1050	7.24	960	6.62	830	5.72	530	3.65
17	830	5.72	750	5.17	660	4.55	420	2.90
21	660	4.55	600	4.14	530	3.65	330	2.28
26	530	3.65	480	3.31	420	2.90	260	1.79

[A] The fiber stresses used to derive these test pressures are as follows:

ABS2112	6600 psi (45.5 MPa)
ABS1316	6000 psi (41.4 MPa)
ABS1210	5240 psi (36.2 MPa)
ABS1208	3300 psi (22.8 MPa)

Some minor adjustments have been made to keep the test pressures uniform to simplify testing.

7.2 *Test Conditions*—Conduct the tests in the Standard Laboratory Atmosphere of 23 ± 2°C and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

7.3 *Sampling*—The selection of the sample or samples of pipe shall be as agreed upon by the purchaser and the seller. In case of no prior agreement, any sample selected by the testing laboratory shall be deemed adequate.

7.3.1 *Test Specimens*—Not less than 50 % of the test specimens required for any pressure test shall have at least a part of the marking in their central sections. The central section is that portion of pipe which is at least one pipe diameter away from an end closure.

7.4 *Dimensions and Tolerances*—Use any length of pipe to determine the dimensions. Measure in accordance with Test Method D 2122.

7.4.1 *Outside Diameter*—Measure the outside diameter of the pipe in accordance with Test Method D 2122. The average

Copyright by the ASTM International
Wed Feb 02 01:48:59 2005

outside diameter is the arithmetic average of the maximum and minimum diameters at any cross section on the length of the pipe. The tolerances for out-of-roundness shall apply only on pipe before shipment.

7.4.2 *Wall Thickness*—Make micrometre measurements of the wall thickness in accordance with Test Method D 2122 to determine the maximum and minimum values. Measure the wall thickness at both ends of the pipe to the nearest 0.001 in. (0.02 mm).

7.4.3 *Wall Thickness Range*—Measure in such a manner that the maximum, *A*, and the minimum, *B*, wall thicknesses of each cross section measured are obtained. Calculate the wall thickness range, *E*, in percent, for each cross section as follows:

$$E = [(A - B)/A] \times 100$$

The wall thickness range shall not exceed 12 % for any cross section measured.

7.5 *Sustained Pressure Test*—Select the test specimens at random. Test individually with water at the internal pressures given in Table 3, six specimens of pipe, each specimen at least ten times the nominal diameter in length, but not less than 10 in. (250 mm) or more than 3 ft (920 mm) between end closures and bearing the permanent marking on the pipe. Maintain the specimens at the pressure indicated for a period of 1000 h. Hold the pressure as closely as possible, but within ±10 psi (±70 kPa). Condition the specimens at the test temperature of 73°F (23°C) to within ±3.6°F (±2°C). Maintain the test temperature at 73 ± 3.6°F (23 ± 2°C). Test in accordance with Test Method D 1598, except maintain the pressure at the values given in Table 3 for 1000 h. Failure of two of the six specimens tested shall constitute failure in the test. Failure of one of the six specimens tested is cause for retest of six additional specimens. Failure of one of the six specimens tested in retest shall constitute failure in the test. Evidence of failure of the pipe shall be as defined in Test Method D 1598.

7.6 *Burst Pressure*—Determine the minimum burst pressure with at least five specimens in accordance with Test Method D 1599. The time of testing each specimen shall be between 60 and 70 s.

8. Retest and Rejection

8.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and the seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

9. Marking

9.1 *Quality of Marking*—The marking shall be applied to the pipe in such a manner that it remains legible (easily read) after installation and inspection.

9.2 Marking on the pipe shall include the following, spaced at intervals of not more than 5 ft:

9.2.1 Nominal pipe size (for example, 2 in.).

9.2.2 Type of plastic pipe material in accordance with the designation code given in 3.2.6 (for example, ABS1210).

9.2.3 Standard thermoplastic pipe dimension ratio in accordance with the designation code given in 5.2 (for example, SDR17), or the pressure rating in pounds per square inch for water at 73°F (23°C) shown as the number followed by psi (for example, 125 psi), except that when intended for pressure application the pressure rating shall be shown (for example, 125 psi). When the indicated pressure rating is lower than that calculated in accordance with 3.2.5 (see Appendix), the SDR shall also be included in the marking code.

9.2.4 This designation "ASTM D 2282," with which the pipe complies.

9.2.5 Manufacturer's name (or trade mark) and code.

9.2.6 Pipe intended for the transport of potable water shall also include the seal or mark of the laboratory making the evaluation for this purpose, spaced at intervals specified by the laboratory. Pipe produced by simultaneous multiple coextrusion shall be marked "CoeX" in accordance with 5.1.

10. Quality Assurance

10.1 When the product is marked with this designation, D 2282, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to Federal/Military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S3. Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

APPENDIX

(Nonmandatory Information)

X1. SOURCE OF HYDROSTATIC DESIGN STRESSES

X1.1 The hydrostatic design stresses recommended by the Plastics Pipe Institute are used to pressure rate ABS plastic pipe. These hydrostatic design stresses are 800 psi (5.5 MPa), 1000 psi (6.9 MPa), 1250 psi (8.6 MPa), and 1600 psi (11.0 MPa) for water at 73°F (23°C). These hydrostatic design stresses apply only to pipe meeting all the requirements of this specification.

X1.2 Four ABS pipe materials are included based on the requirements of Specification D 3965 and the PPI-recommended hydrostatic design stresses as follows:

X1.2.1 Type 1, Grade 2, with a hydrostatic design stress of 800 psi (5.5 MPa) for water at 23°C, designated as ABS1208.

X1.2.2 Type 1, Grade 2, with a hydrostatic design stress of 1000 psi (6.9 MPa) for water at 23°C, designated as ABS1210.

X1.2.3 Type 1, Grade 3, with a hydrostatic design stress of 1600 psi (11.0 MPa) for water at 23°C, designated as ABS1316.

X1.2.4 Type 2, Grade 1, with a hydrostatic design stress of 1250 psi (8.6 MPa) for water at 23°C, designated as ABS2112.

X1.3 Information regarding the criteria used in developing these hydrostatic design stresses may be obtained from the Plastics Pipe Institute, a division of The Society of the Plastics Industry, 355 Lexington Ave., New York, NY 10017 (Note X1.1). These hydrostatic design stresses may not be suitable for materials that show a wide departure from a straight-line plot of log stress versus log time to failure. All the data available to date on ABS pipe materials made in the United States exhibit a straight-line plot under these plotting conditions.

NOTE X1.1—Refer also to Test Method D 2837.

X1.4 The pipe is rated for use with water at 23°C at the maximum internal pressures shown in Table X1.1 (see also Table X1.2). Lower pressure ratings than those calculated in accordance with 6.5 may be recommended, at the option of the pipe manufacturer, in which case the SDR shall be included in

3	0	4	4	4	Type 2, Grade 1

the marking. Experience of the industry indicates that ABS plastic pipe meeting the requirements of this specification gives satisfactory service under normal conditions for a long period at these pressure ratings. The sustained pressure requirements (6.4) are related to these ratings through the slopes of the strength-time plots of these materials in pipe form.

Designation: D 2310 – 01

An American National Standard

Standard Classification for Machine-Made "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe[1]

This standard is issued under the fixed designation D 2310; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope *

1.1 This classification covers machine-made "fiberglass" (glass-fiber-reinforced thermosetting-resin) pressure pipe. Methods of classification, requirements, test methods and the method of marking are included. Both glass-fiber-reinforced thermosetting-resin pipe (RTRP) and glass-fiber-reinforced polymer mortar pipe (RPMP) are fiberglass pipes.

NOTE 1—For the purposes of this standard, polymer does not include natural polymers.

1.2 This classification is based on the method of manufacture, the type of materials used in construction, and the test performance of the product type. It is not based on dimensions or raw material specifications.

1.3 Two methods of classifying long-term strength are included: (*1*) based on cyclic loads for use in those liquid-handling applications where the effects of pumping by duplex or triplex pumps or other cyclic pressure loads dictate the performance requirements of the piping, and (*2*) based on the steady (static) loads such as would be required for gas service applications.

1.4 The values stated in inch-pound units are to regarded as the standard. The values in parentheses are provided for information only.

1.5 The following precautionary caveat pertains only to the test method portion, Section 7, of this classification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 2—There is no similar or equivalent ISO standard.

2. Referenced Documents

2.1 *ASTM Standards:*

D 883 Terminology Relating to Plastics[2]

D 1600 Terminology for Abbreviated Terms Relating to Plastics[2]

D 2992 Practice for Obtaining Hydrostatic or Pressure Design Basis for "Fiberglass" (Glass-Fiber Reinforced Thermosetting Resin) Pipe and Fittings[3]

D 3567 Practice for Determining Dimensions of "Fiberglass" (Glass-Fiber-Reinforced Thermosetting Resin) Pipe and Fittings[3]

F 412 Terminology Relating to Plastic Piping Systems[3]

3. Terminology

3.1 General—Definitions are in accordance with Terminology D 883 or F 412 and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated.

3.2 *Definitions of Terms Specific to This Standard:* Description of Terms Specific to This Standard:

3.2.1 *fiberglass pipe, n*—a tubular product containing glass fiber reinforcements embedded in or surrounded by cured thermosetting resin; the composite structure may contain aggregate, granular, or platelet fillers, thixotropic agents, pigments, or dyes; thermoplastic or thermosetting liners or coatings may be included.

3.2.2 *reinforced thermosetting resin pipe (RTRP), n*—a fiberglass pipe without aggregate.

3.2.3 *reinforced polymer mortar pipe (RPMP), n*—a fiberglass pipe with aggregate.

3.2.4 *centrifugal casting, n*— a manufacturing process used to produce tubular goods by applying resin and reinforcement to the inside of a mold that is rotated and heated, subsequently polymerizing the resin system. The outside diameter of the finished pipe is fixed by the inside diameter of the mold tube. The inside diameter of the pipe is determined by the amount of material introduced into the mold.

3.2.5 *filament winding, n*—a process used to manufacture tubular goods by winding continuous fibrous glass strand roving or roving tape onto the outside of a mandrel in a predetermined pattern under controlled tension; the roving may be saturated with liquid resin or preimpregnated with partially cured resin; subsequent polymerization of the resin system may require application of heat; the inside diameter of the finished pipe is fixed by the mandrel outside diameter; the outside

diameter of the finished pipe is determined by the amount of material that is wound onto the mandrel.

3.2.6 *liner, n*—the inner portion of the wall, at least 0.005 in. (0.13 mm) in thickness when determined in accordance with Practice D 3567, that does not contribute to the strength in the determination of the hydrostatic design basis.

3.2.7 *pressure laminating, n*—a process to manufacture tubular goods in which reinforcement is impregnated with a thermosetting resin, and the resin partially cured to form a prepreg; it is subsequently laminated around a mandrel and cured under heat and pressure to form the pipe; the pipe is then removed from the mandrel and postcured. The inside diameter of the finished pipe is fixed by the mandrel outside diameter; the outside diameter of the finished pipe is determined by the amount of material that is wound onto the mandrel.

3.2.8 *aggregate, n*—a siliceous sand conforming to the requirements of Specification C 33, except that the requirements for gradation shall not apply.

4. Basis of Classification

4.1 *General*—This classification covers machine-made fiberglass pipe defined by method of manufacturing (type), raw materials in body (grade), liner material (class), and long-term cyclic pressure strength or long-term static pressure strength, whichever is applicable. It covers the following types, grades, and classes of machine-made fiberglass pipe:

NOTE 3—All possible pressure strength combinations of types, grades, and classes may not be commercially available.

4.1.1 *Types:*—Type I
Filament-wound pipe
Type II—Centrifugally cast pipe
Type III—Pressure-laminated pipe

4.1.2 *Grades:*—Grade 1
Glass-fiber-reinforced epoxy resin pipe (RTRP epoxy)
Grade 2—Glass-fiber-reinforced polyester resin pipe (RTRP polyester)
Grade 3—Glass-fiber-reinforced phenolic resin pipe (RTRP phenolic)
Grade 7—Glass-fiber-reinforced furan resin pipe (RTRP furan)
Grade 8—Glass-fiber-reinforced epoxy resin mortar pipe (RPMP epoxy)
Grade 9—Glass-fiber-reinforced polyester resin mortar pipe (RPMP polyester)

4.1.3 *Classes:*—Class A
No liner
Class B—Polyester resin liner (nonreinforced)
Class C—Epoxy resin liner (nonreinforced)
Class D—Phenolic resin liner (nonreinforced)
Class E—Polyester resin liner (reinforced)
Class F—Epoxy resin liner (reinforced)
Class G—Phenolic resin liner (reinforced)
Class H—Thermoplastic resin liner (specify)
Class I—Furan resin liner (reinforced)

4.1.4 *Pressure Strength*—Two methods of classifying the pressure strength of the pipe are incorporated in this document; one or both may be used. Pipe meeting this classification shall be identified by one or both of the hydrostatic design bases shown in Table 1.

4.1.5 *Designation Requirements*—The pipe materials designation code shall consist of the abbreviation RTRP or RPMP, followed by type and grade in arabic numerals, class by a

TABLE 1 General Designation Requirements[A] for Machine-Made Fiberglass Pipe

Designation Order	Property	Cell Limits								
1	Type	1 filament-wound	2 centrifugally cast	3 pressure-laminated						
2	Grade	1 glass-fiber-reinforced epoxy resin (RTRP)	2 glass-fiber-reinforced polyester resin (RTRP)	3 glass-fiber-reinforced phenolic resin (RTRP)				7 glass-fiber-reinforced furan resin (RTRP)	8 glass-fiber-reinforced epoxy resin (RPMP)	9 glass-fiber-reinforced polyester resin mortar (RPMP)
3	Class	A no liner	B polyester resin liner (nonreinforced)	C epoxy resin liner (nonreinforced)	D phenolic resin liner (nonreinforced)	E polyester resin liner (reinforced)	F epoxy resin liner (reinforced)	G phenolic resin liner (reinforced)	H thermoplastic resin liner (specify)	I furan resin liner (reinforced)
		Hoop Stress—Hydrostatic Design Basis[B]								
		A	B	C	D	E	F	G	H	
4	Cyclic psi (MPa)	2500 (17.2)	3150 (21.7)	4000 (27.5)	5000 (34.4)	6300 (43.4)	8000 (55.1)	10 000 (68.9)	12 500 (86.1)	
or		Q	R	S	T	U	W	X	Y	Z
4	Static psi (MPa)	5000 (34.4)	6300 (43.4)	8000 (51.5)	10 000 (68.9)	12 500 (86.1)	16 000 (110.0)	20 000 (137.0)	25 000 (172.0)	31 500 (217.0)

[A] The cell-type format provides the means of identification and specification of piping materials. This cell-type format, however, is subject to misapplication since unobtainable property combinations can be selected if the user is not familiar with commercially available products. The manufacturer should be consulted.
[B] Refer to Practice D 2992 to obtain classification of the values.

Copyright by the ASTM International
Wed Feb 02 01:49:38 2005

capital letter, and the long-term strength by a second capital letter. Table 1 presents a summary of the designation requirements. Thus a complete material code shall consist of RTRP or RPMP . . . two numerals, and two letters.

4.1.5.1 *Examples*:

(*1*) RTRP-11AE for filament-wound glass-fiber-reinforced epoxy resin pipe, unlined, with a 6300 psi (43.4 MPa) (cyclic) hydrostatic design basis, or

(*2*) RTRP-11AT for filament-wound glass-fiber-reinforced epoxy resin pipe, unlined, with a 10 000 psi (68.9 MPa) (static) hydrostatic design basis, or

(*3*) both, if the pipe is to be dual rated.

NOTE 4—Although *Form and Style for ASTM Standards* requires that the type classification be roman numerals, it is recognized that few companies have stencil-cutting equipment for this style of type, and it is, therefore, acceptable to mark the product type in arabic numerals. Precedence for this change has been made in other ASTM standards.

5. Materials

5.1 *General*—The resins, reinforcements, and other materials, when combined as a composite structure, shall produce a pipe that shall meet the performance requirements of this classification.

6. Requirements

6.1 *Properties*:

6.1.1 *Hydrostatic Design Basis*—The hydrostatic design basis for products meeting this classification is derived from the long-term pressure strength, as determined at ambient temperature in accordance with 7.1 or 7.2. Standard categories for the hydrostatic design basis are shown in Table 1. A hydrostatic design basis as shown in Table 1 shall be determined for each type, grade, and class of product manufactured. Changes in materials or manufacturing processes will necessitate a screening evaluation as described in Practice D 2992.

6.1.2 *Pressure Rating*—The hydrostatic design stress for products meeting this classification is obtained by multiplying the applicable hydrostatic design basis (from Table 1) by a service (design) factor equal to or less than 1.0.

NOTE 5—Information regarding selection of service (design) factors and pressure rating is provided in Practice D 2992 and the individual product standards.

7. Test Methods

7.1 *Cyclic Pressure Strength*—Determine the cyclic pressure strength in accordance with Procedure A of Practice D 2992.

7.2 *Static Pressure Strength*—Determine the static pressure strength in accordance with Procedure B of Practice D 2992.

8. Marking

8.1 Marking on the pipe shall include the following items, spaced at intervals of not more than 15 ft (4.5 m):

8.1.1 Nominal pipe size (example: 2 in.),

8.1.2 Type of fiberglass pipe, in accordance with the designation code given in 4.1.5,

8.1.3 ASTM pipe product specification with which the pipe complies, and

8.1.4 Manufacturer's name (or trademark).

8.2 All markings shall be such that they will remain legible under normal handling and installation practices.

9. Keywords

9.1 centrifugal casting; fiberglass pipe; filament winding; hydrostatic design basis; machine-made fiberglass pressure pipe; pipe; pressure laminating; pressure strength; reinforced polymer mortar pipe (RPMP); reinforced thermosetting-resin pipe (RTRP)

SUMMARY OF CHANGES

Committee D-20 has identified the location of selected changes to this classification since the last issue D 2310–97 that may impact the use of this classification.

(*1*) Changed acronym, RPMP, definition from reinforced *plastic* mortar pipe to reinforced *polymer* mortar pipe.

Standard Specification for Threaded Poly(Vinyl Chloride) (PVC) Plastic Pipe Fittings, Schedule 80[1]

This standard is issued under the fixed designation D 2464; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers poly(vinyl chloride) (PVC) threaded Schedule 80 pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—Threaded CPVC plastic pipe fittings, Schedule 80, which were formerly included in this standard, are now covered by Specification F 437.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 2—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious saftey hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 7, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Standard No. 61 for Drinking Water Systems Components—Health Effects[5]

3. Terminology

3.1 General—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for poly(vinyl chloride) plastic is PVC.

4. Classification

4.1 *General*—This specification covers threaded Schedule 80 PVC pipe fittings, made from four PVC plastic compounds and intended for use with threaded Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings,

[1] This specification is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.10 on Fittings.

caps, nipples, etc., shall be molded or machined from extruded stock.

4.1.2 Fittings fabricated by back welding or butt fusion are not included in this specification.

5. Materials and Manufacture

5.1 This specification covers PVC pipe fittings made from five PVC plastics as classified in Specification D 1784. These are PVC 12454-B, 12454-C, 13354-C, 11443-B, and 14333-D.

NOTE 3—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.2 *Rework Material*—The manufacturers shall use only their own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *Dimensions and Tolerances*:

6.1.1 The dimensions and tolerances of the fittings shall be as shown in Table 1 and Table 2 when measured in accordance with Test Method D 2122. Minimum dimensions have zero negative tolerances. Bushings shall have thread lengths applicable to the corresponding sizes. Counterbore is optional, is not shown in Table 1, and is not included in the center-to-end or end-to-end dimensions.

6.1.2 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

6.1.3 *Fittings Not Illustrated*—All fittings, whether illustrated in Table 1 and Table 2 or not, shall have wall thicknesses and thread dimensions conforming to 6.1 and 6.2.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.3.1 The burst strength of the fittings shall be not less than that calculated for the size and wall thickness of the pipe with which it is to be used, when calculated from the following equation:

$$S = P(D_O t)/2t \quad (1)$$

where:

S = hoop stress, psi (or MPa),
P = internal pressure, psi (or MPa),
D_O = average outside diameter, in. (or mm), and
t = minimum wall thickness, in. (or mm).

Fittings tested in accordance with 8.4 shall withstand the minimum burst pressure shown in Table 3.

6.3.2 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish, and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the Standard Laboratory Atmosphere of 73 ± 3.6 °F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

[A]The sketches and designs of fittings shown are illustrative only.
[B]At the manufacturer's option the head of the plug shall be hexagonal, octagonal, square, or round.

TABLE 3 Burst Pressure Requirements for Water at 73°F (23°C) for PVC Threaded Pipe Fittings, Schedule 80

Nominal Size, in.	Minimum Burst Strength[A]			
	Classes 12454, 13354,-C and 11443		Class 14333	
	psi	MPa	psi	MPa
1/4	3620	(24.96)	2830	(19.51)
3/8	2940	(20.27)	2300	(15.86)
1/2	2720	(18.75)	2120	(14.62)
3/4	2200	(15.17)	1720	(11.86)
1	2020	(13.93)	1580	(10.89)
1 1/4	1660	(11.44)	1300	(8.96)
1 1/2	1510	(10.41)	1180	(8.14)
2	1290	(8.89)	1010	(6.96)
2 1/2	1360	(8.38)	1060	(7.31)
3	1200	(8.27)	940	(6.48)
4	1040	(7.17)	810	(5.51)
6	890	(6.19)	700	(4.83)

[A]This table was calculated for Schedule 80 pipe using the ISO formula and the stress levels for materials as follows:

	psi	MPa
Classes 11443, 13354, -C and 12454	6400	44.1
Class 14333	5000	34.5

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 4—For individual orders or specifications where supplemental tests are required, only those tests and numbers of tests specifically agreed upon between purchaser and supplier need be conducted.

8.4 *Burst Pressure*—Determine the minimum burst pressure with at least five specimens in accordance with Test Method D 1599. Join the fittings to the pipe sufficiently strong and in such a manner that no failures shall occur in the assembly at a pressure less than the pressure requirement given in Table 3. The time of testing each assembly shall be between 60 and 70 s.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and seller. Under such agreement, minimum requirements shall not be lowered, changed or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Product Marking

10.1 *Quality of Marking*—The marking shall be applied to the fittings in such a manner that they remain legible under normal handling and installation practices.

10.2 *Content of Marking*:

10.2.1 Fittings shall be marked with the following:

10.2.1.1 Manufacturer's name or trademark,

10.2.1.2 Material designation PVC I for PVC 12454-B, PVC 12 for PVC 12454-C, PVC 13 for PVC 13354-C and 11443-B, PVC II for PVC 14333-D,

10.2.1.3 The seal or mark of the laboratory making the evaluation for potable water contact.

10.2.1.4 Size, and

10.2.1.5 This designation, D 2464, with which this fitting complies.

10.3 Where the size of the fittings does not allow complete marking, omit identification marking in the following sequence: size, material designation, D 2464, manufacturer's name or trademark.

10.4 Markings or symbols shall be molded, hot-stamped, or

Copyright by the ASTM International
Wed Feb 02 01:50:21 2005

applied to fittings by any other suitable method, such as printing.

10.5 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

11. Quality Assurance

11.1 When the product is marked with this designation, D 2464, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

The following requirements apply only to federal/military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD 129 for military agencies.

NOTE S2.1—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this specification.

ADDITIONAL SUPPLEMENTARY REQUIREMENTS

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S3. *Potable Water Requirement*—Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: D 2466 – 01

An American National Standard

Standard Specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe Fittings, Schedule 40[1]

This standard is issued under the fixed designation D 2466; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers poly(vinyl chloride) (PVC) Schedule 40 pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—Socket-type CPVC plastic pipe fittings, Schedule 40, which were formerly included in this standard, are now covered by Specification F 438.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 2—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious saftey hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 7, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

D 618 Practice for Conditioning Plastics for Testing[2]

D 1599 Test Method for Short-Time Hydraulic Failure Pressure of Plastic Pipe, Tubing, and Fittings[3]

D 1600 Terminology for Abbreviated Terms Relating to Plastics[2]

D 1784 Specification for Rigid Poly(Vinyl Chloride) (PVC) Compounds and Chlorinated Poly(Vinyl Chloride) (CPVC) Compounds[2]

D 2122 Test Method for Determining Dimensions of Thermoplastic Pipe and Fittings[3]

F 412 Terminology Relating to Plastic Piping Systems[3]

F 438 Specification for Socket-Type Chlorinated Poly(Vinyl Chloride) (CPVC) Plastic Pipe Fittings, Schedule 40[3]

F 1498 Specification for Taper Pipe Threads 60° for Thermoplastic Pipe and Fittings[3]

2.2 *NSF Standards:*

Standard No. 14 for Plastic Piping Components and Related Materials[4]

Standard No. 61 for Drinking Water Systems Components—Health Effects[4]

3. Terminology

3.1 General—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for poly(vinyl chloride) plastic is PVC.

4. Classification

4.1 *General*—This specification covers Schedule 40 PVC pipe fittings, made from four PVC plastic compounds and intended for use with Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings, caps, nipples, etc., shall be molded or machined from extruded stock.

---

[1] This specification is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.10 on Fittings.

Current edition approved April 10, 2001. Published June 2001. Originally published as D 2466 – 65 T. Last previous edition D 2466 – 99.

4.1.2 Fittings fabricated by welding are not included in this specification.

5. Materials

5.1 This specification covers PVC pipe fittings made from five PVC plastics as classified in Specification D 1784. These are PVC 12454-B, 12454-C, 13354-C, 11443-B, and 14333-D.

5.2 *Compound*—The PVC plastic compound shall meet the requirements of PVC 12454-B, 12454-C, 11443-B, or 14333-D, as described in Specification D 1784.

NOTE 3—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.3 *Rework Material*—The manufacturers shall use only their own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

6. Requirements

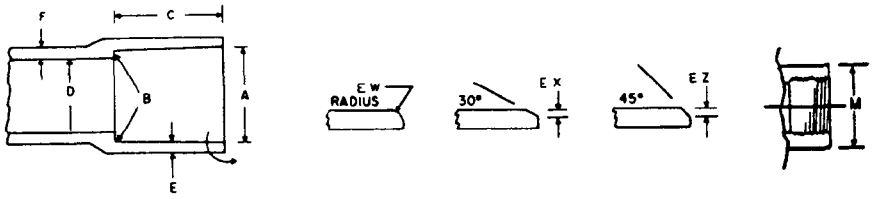
6.1 *Dimensions and Tolerances*:

6.1.1 Fitting sockets inside diameters (waterways), minimum wall thicknesses, and dimensions shall be as shown in Table 1, Table 2, and Table 3 when measured in accordance with Test Method D 2122.

6.1.2 When multistep reducer bushings are cored out, the inner socket shall be reinforced from the outer wall by a minimum of three ribs extending from the top of the inner socket to the deepest extremity of the coring. The transition from D to DJ (Table 3) shall be straight, tapered as shown, or radiused. A positive taper in the same direction of the taper in the socket on the outside diameter of the bushing is optional.

6.1.3 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

TABLE 1 Tapered Sockets for PVC Pipe Fittings, Schedule 40, in.[A]



Nominal Pipe Size	A Socket Entrance Diameter			B Socket Bottom Diameter			C[B] Socket Length, min	D[C] Inside Diameter, min	Wall Thickness, min		Min Outside Diameter of Hub, M	Entrance, min

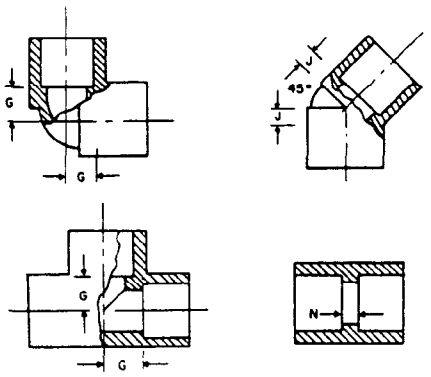
TABLE 2 Minimum Dimension from Center to End of Sockets (Laying Length) for Couplings, Tees, 90° and 45° Elbows, PVC Socket-Type Pipe Fittings, Schedule 40, in.[A]



Nominal Pipe Size	G, min	J, min	N, min
⅛	¼	⅛	1/16
¼	5/16	5/32	1/16
⅜	⅜	3/16	3/32
½	½	¼	3/32
¾	9/16	5/16	3/32
1	11/16	5/16	3/32
1¼	⅞	⅜	3/32
1½	1	7/16	3/32
2	1¼	⅝	3/32
2½	1½	11/16	3/16
3	1 13/16	¾	3/16
3½	2⅛	1	3/16
4	2 5/16	1	3/16
5	3	1⅜	3/16
6	3½	1¾	¼
8	4½	2	¼
10	5 13/16	2 9/16	¼
12	6 15/16	3 1/16	¼

[A] The sketches and designs of fittings are illustrative only.

6.1.4 The minimum wall thickness of fittings shall be 125 % of the minimum wall thickness of the corresponding size of Schedule 40 pipe for which they are designed to be used, except that for the socket, the wall thickness shall be at least equal to the minimum wall thickness of the corresponding size of Schedule 40 pipe. For any threaded fitting the minimum wall thickness of the threaded portion shall be at least equal to the thickness of material under the thread root of threaded Schedule 80 pipe of the same size.

6.1.5 The minimum inside diameter of the fittings shall be not less than the minimum specified inside diameter of the corresponding size of Schedule 40 pipe. Any fitting having a male thread shall have an internal diameter not larger than Schedule 80 pipe of the same size.

6.1.6 Minimum dimensions have zero negative tolerance. Tolerances on other dimensions are shown in Table 1 and Table 3.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.3.1 The minimum burst strength of the fittings shall be not less than that calculated for the size and wall thickness of the pipe with which it is to be used, when calculated from the following equation:

$$S = P\,(D_O - t)/2t \quad (1)$$

where:

S = hoop stress, psi (or MPa),
P = internal pressure, psi (or MPa),
D_O = average outside diameter, in. (or mm), and
t = minimum wall thickness, in. (or mm).

Fittings tested in accordance with 8.5 shall withstand the minimum burst pressure shown in Table 4.

6.3.2 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish, and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 73 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the Standard Laboratory Atmosphere of 73 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 4—For individual orders or specifications, only those tests and numbers of tests specifically agreed upon between the purchaser and the seller need be conducted.

8.4 *Threads*—All taper pipe threads shall be gaged in accordance with Specification F 1498.

8.5 *Burst Pressure*—Determine the minimum burst pressure in accordance with Test Method D 1599. The pressure shall be applied at a uniform rate such that the minimum allowable burst pressure is attained in 60 or 70 s.

NOTE 5—The time-to-failure may exceed 70 s.

8.5.1 *Apparatus*—Fittings shall be tested while held in a test jig constructed in such a manner as to seal the socket by means of O-rings, or gaskets but not to reinforce or support the fittings, except where contact is necessary because of the shape of the fitting to keep the fitting in the test jig. Such contact shall be held to the minimum. The socket plug portion of the test fixture must extend one third to two thirds of the socket depth. Failure of any part of the test apparatus does not constitute failure of the fittings.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the tests(s) shall be conducted again only by agreement between the purchaser and seller. Under such

If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Marking

10.1 Fittings shall be marked with the following:

10.1.1 Manufacturer's name or trademark,

10.1.2 Material designation PVC I for PVC 12454-B, PVC 12 for PVC 12454-C, PVC 13 for PVC 13354-C and 11443-B, and PVC II for PVC 14333-D,

10.1.3 Fittings intended for the transport of potable water shall include the seal or mark of the laboratory making the evaluation for this purpose.

10.1.4 Size, and

10.1.5 This designation number: D 2466.

10.2 Where the size of the fitting does not allow complete marking, omit identification marking in the following sequence: size, material designation, manufacturer's name or trademark.

10.3 Markings or symbols shall be molded, hot-stamped, or applied to fittings by any other suitable method, such as printing.

10.4 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

11. Quality Assurance

11.1 When the product is marked with this designation, D 2466, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

12. Keywords

12.1 fittings; pressure; PVC; Sch 40; sockets; threads

SUPPLEMENTARY REQUIREMENTS

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S1. Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: D 2467 – 01

An American National Standard

Standard Specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe Fittings, Schedule 80[1]

This standard is issued under the fixed designation D 2467; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers poly(vinyl chloride) (PVC) Schedule 80 pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—CPVC plastic pipe fittings, which were formerly included in this standard, are now covered in Specification F 439.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 2—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious saftey hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 8, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2 *Federal Standard:*

Fed. Std. No. 123 Marking for Shipment (Civil Agencies)[4]

2.3 *National Sanitation Foundation Standard:*

Standard No. 14 for Plastic Piping Components and Related Materials[5]

Standard No. 61 for Drinking Water Systems Components—Health Effects[5]

3. Terminology

3.1 General—Definitions are in accordance with Terminology F 412 and abbreviations are in accordance with Teminology D 1600, unless otherwise indicated. The abbreviation for poly(vinyl chloride) plastic is PVC.

4. Classification

4.1 *General*—This specification covers Schedule 80 PVC pipe fittings, socket-type, made from four PVC plastic compounds and intended for use with Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings,

[1] This specification is under the jurisdiction of ASTM Committee F17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.10 on Fittings.

caps, nipples, etc., shall be molded or machined from extruded stock.

4.1.2 Fittings fabricated by back welding or butt fusion are not included in this specification.

5. Materials and Manufacture

5.1 This specification covers PVC pipe fittings made from five PVC plastics as classified in Specification D 1784. These are PVC 12454-B, 12454-C, 13354-C, 11443-B, and 14333-D.

5.2 *Compound*—The PVC plastic compound shall meet the requirements of PVC 12454-B, 12454-C, 11443-B, or 14333-D, as described in Specification D 1784.

NOTE 3—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.3 *Rework Material*—The manufacturers shall use only their own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *Dimensions and Tolerances*:

6.1.1 Fitting sockets inside diameters (waterways), minimum wall thicknesses, and dimensions shall be as shown in Tables 1-4 when measured in accordance with Test Method D 2122.

6.1.2 When multistep reducer bushings are cored out, the inner socket shall be reinforced from the outer wall by a minimum of three ribs extending from the top of the inner socket to the deepest extremity of the coring. The transition from D to DJ (Table 3) shall be straight, tapered as shown, or radiused. A positive taper in the same direction of the taper in the socket on the outside diameter of the bushing is optional.

6.1.3 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

6.1.4 The minimum wall thickness of fittings shall be 125 % of the minimum wall thickness of the corresponding size of Schedule 80 pipe for which they are designed to be used, except that for the socket, the wall thickness shall be at least equal to the minimum wall thickness of the corresponding size of Schedule 80 pipe.

6.1.5 The minimum inside diameter of the fittings shall be not less than the minimum specified inside diameter of the corresponding size of Schedule 80 pipe.

6.1.6 Minimum dimensions have zero negative tolerance. Tolerances on other dimensions are shown in Table 1 and Table 3.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.4 . Fittings tested in accordance with 8.5 shall withstand the minimum burst pressure shown in Table 5.

6.4.1 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish, and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the Standard Laboratory Atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 4—For individual orders or specifications where supplemental tests are required, only those tests and numbers of tests specifically agreed upon between purchaser and seller need be conducted.

8.4 *Threads*—All taper pipe threads shall be gaged in accordance with Specification F 1498.

8.5 *Burst Pressure*—Determine the minimum burst pressure in accordance with Test Method D 1599. The pressure shall be applied at a uniform rate such that the minimum allowable burst pressure is attained in 60 to 70 s.

NOTE 5—The time-to-failure may exceed 70 s.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the tests(s) shall be conducted again only by agreement between the purchaser and seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Product Marking

10.1 *Quality of Marking*—The markings shall be applied to the fittings in such a manner that they remain legible under normal handling and installation practices.

10.2 *Content of Marking*—Fittings shall be marked with the following:

10.2.1 Material designation PVC I for PVC 12454-B, PVC 12 for PVC 12454-C, PVC 13 for PVC 13354-C and 11443-B, and PVC II for PVC 14333-D,

10.2.2 The seal or mark of the laboratory making the evaluation for potable water contact,

10.2.3 Size, and

10.2.4 This designation, D 2467, with which the fitting complies.

10.3 Where the size of the fitting does not allow complete marking, omit identification marking in the following sequence: size, material designation (D 2467), manufacturer's name, or trademark.

10.4 Marking or symbols shall be molded, hot-stamped, or applied to fittings by any other suitable method, such as printing.

[B] This dimension locates the end of the fitting.

10.5 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

11. Quality Assurance

11.1 *Quality Assurance*—When the product is marked with this designation, D 2467, the manufacturer affirms that the product was inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

12. Keywords

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT / MILITARY PROCUREMENT

These requirements apply *only* to Federal / Military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2.1— The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S3. Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/ NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

An American National Standard

Standard Practice for Heat Fusion Joining of Polyolefin Pipe and Fittings[1]

This standard is issued under the fixed designation D 2657; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice describes general procedures for making joints with polyolefin pipe and fittings by means of heat fusion joining techniques in either a shop or field environment. These procedures are general ones. Specific instructions for heat fusion joining are obtained from product manufacturers.

1.2 The techniques covered are applicable only to joining polyolefin pipe and fittings of related polymer chemistry, for example, polyethylenes to polyethylenes, polypropylenes to polypropylenes, or polybutylenes to polybutylenes. Material, density, and flow rate shall be taken into consideration in order to develop uniform melt viscosities and formation of a good fusion bond, when joining the same material to itself or to other materials of related polymer chemistry.

1.3 Parts that are within the dimensional tolerance given in present ASTM specifications are required to produce sound joints between polyolefin pipe and fittings when using the joining techniques described in this practice.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 The text of this practice references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the practice.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See specific safety precautions in 4.2, 5.1.1, 8.2.3.1, Notes 8 and 9, and A1.1.

2. Referenced Documents

2.1 *ASTM Standards:*

F 905 Practice for Qualification of Polyethylene Saddle Fusion Joints[2]

F 1056 Specification for Socket Fusion Tools for Use in Socket Fusion Joining Polyethylene Pipe or Tubing and Fittings[2]

3. Significance and Use

3.1 The procedures described in Sections 7, 8, and 9, when implemented using suitable equipment and procedures in either a shop or field environment, produce strong pressure-tight joints equal to the strength of the piping material. Some materials are more adaptable to one technique than another. Average molecular weight and molecular weight distribution are influential factors in establishing suitable fusion parameters; therefore, consider the manufacturer's instructions in the use or development of a specific fusion procedure.

4. Operator Experience

4.1 Skill and knowledge on the part of the operator are required to obtain a good quality joint. This skill and knowledge is obtained by making joints in accordance with proven procedures under the guidance of skilled operators. Evaluate operator proficiency by testing sample joints.

4.2 These procedures require the use of heating and cutting equipment. The person actually responsible for the joining of polyolefin pipe and fittings shall ensure that detailed procedures developed in conjunction with the manufacturers of the pipe, fittings, and the joining equipment involved, including the safety precautions to be followed, are issued before actual joining operations begin.

5. Summary of Practice

5.1 Heat-fusion joining uses a combination of heat and force resulting in two melted surfaces flowing together to produce a joint. Fusion bonding occurs when the joint cools below the melt temperature of the material. There is a temperature range within which any particular material is satisfactorily joined. The specific temperature used requires consideration of the properties of the specific material, and the joining environment. With Techniques II or III (5.3.2 or 5.3.3), there is also an appropriate force to be applied which depends upon the material, the fusion equipment being used, and fusion temperature.

5.1.1 Electrically powered heat fusion tools and equipment are usually not explosion proof. When performing heat fusion in a potentially combustible atmosphere such as in an excavation where gas is present, all electrically powered tools and equipment that will be used in the combustible atmosphere shall be disconnected from the electrical power source and operated manually to prevent explosion and fire. For the heating tool, this requires bringing the heating tool up to or slightly above temperature in a safe area, then disconnecting it from electrical power immediately before use. This procedure is limited to smaller sizes where heating is accomplished before the heating tool drops below acceptable temperature.

[1] This practice is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.20 on Joining.

Current edition approved May 10, 1997. Published November 1997. Originally published as D 2657 – 67. Last previous edition D 2657 – 96.

5.2 Adequate joint strength for testing is attained when all of the joint material cools to ambient temperature. The joint shall not be disturbed or moved until it has cooled.

NOTE 1—Polybutylene undergoes a crystalline transformation for several days after cooling below its melt temperature. Although this phenomenon has an effect on the ultimate physical properties of the material, its effect on testing of joints has not been found to be significant. If there is any question of its effect, a comparison should be made between joints that have been conditioned for different periods of time in order to establish the conditioning-time relationship.

5.3 Three fusion techniques are covered in this practice as follows:

5.3.1 *Procedure 1, Socket Fusion*—The socket-fusion technique involves simultaneously heating the outside surface of a pipe end and the inside of a fitting socket, which is sized to be smaller than the smallest outside diameter of the pipe. After the proper melt has been generated at each face to be mated, the two components are joined by inserting one component into the other. See Fig. 1. The fusion bond is formed at the interface resulting from the interference fit. The melts from the two components flow together and fuse as the joint cools. Optional alignment devices are used to hold the pipe and socket fitting in longitudinal alignment during the joining process; especially with pipe sizes 3 in. IPS (89 mm) and larger.

5.3.2 *Procedure 2, Butt Fusion*—The butt-fusion technique in its simplest form consists of heating the squared ends of two pipes, a pipe and a fitting, or two fittings, by holding them against a heated plate, removing the plate when the proper melt is obtained, promptly bringing the ends together, and allowing the joint to cool while maintaining the appropriate applied force. See Fig. 2. An alignment jig shall be used to obtain and maintain suitable alignment of the ends during the fusion operation.

5.3.3 *Procedure 3, Saddle Fusion*—The saddle-fusion technique involves melting the concave surface of the base of a saddle fitting, while simultaneously melting a matching pattern on the surface of the pipe, bringing the two melted surfaces together and allowing the joint to cool while maintaining the appropriate applied force. See Fig. 3.

6. Apparatus: General Recommendations

6.1 *Heating Tool*—The tool may be heated by gas or electricity. Gas-fired heaters shall have heat sinks of sufficient capacity to prevent excessive draw down of the tool temperature. Electric heating plates maintain consistent fusion temperatures when provided with an adequate power source. Electric heating plates for general fusion use shall be controlled thermostatically and adjusted over a temperature range from 300 to 575°F (150 to 300°C). Some tools may have a fixed set point for a particular application.

6.2 *Heating Tool Faces*—Heating tools may be made from materials such as aluminum, stainless steel, copper, or copper alloys. Copper or copper-alloy heating faces are not suitable, unless chromium-plated or clad with another suitable metal, because some polyolefins react with copper. Plastic materials may stick to hot metal heating surfaces. This sticking may be minimized by applying a non-stick coating to the heating surfaces or by fitting a high-temperature, non-stick fabric over the heating surfaces. The heating plate surfaces, coated or uncoated, shall be kept clean and free of contaminants such as dirt, grease and plastic build-up, which may cause excessive sticking and create unsatisfactory joints. Most of these contaminants are removed from the hot tool surfaces using a clean, dry, oil-free lint-free cloth. Do not use synthetic fabrics which may char and stick to the fusion surface. Some pigments, such as carbon black, may stain a heating surface and probably cannot be removed; such stains will not contaminate the joint interface.

6.2.1 After a period of time in service, non-stick coatings or fabrics will deteriorate and become less effective. Deteriorated fabrics should be replaced, and worn, scratched, or gouged non-stick coatings should be re-coated when they lose effectiveness. Heat fusion quality may be adversely

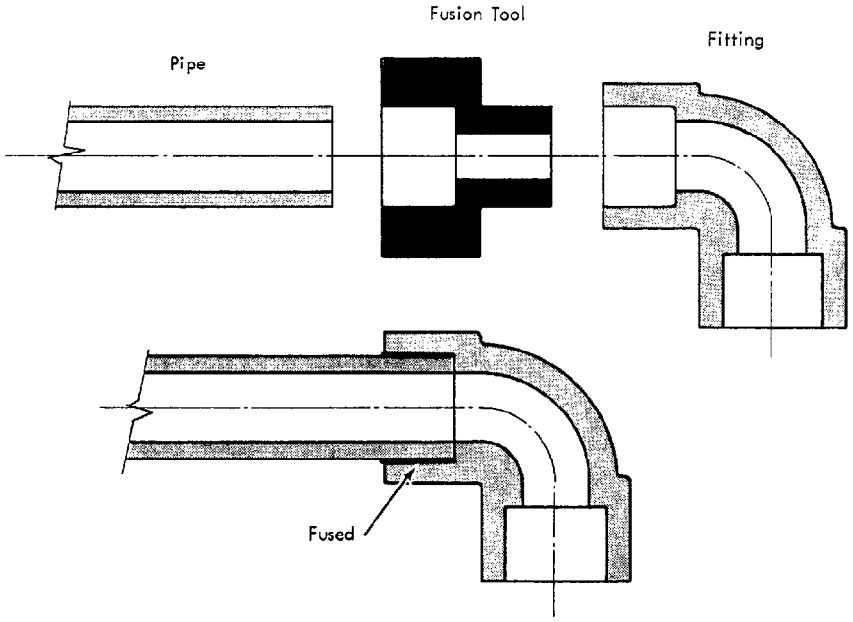

FIG. 1 Socket Fusion

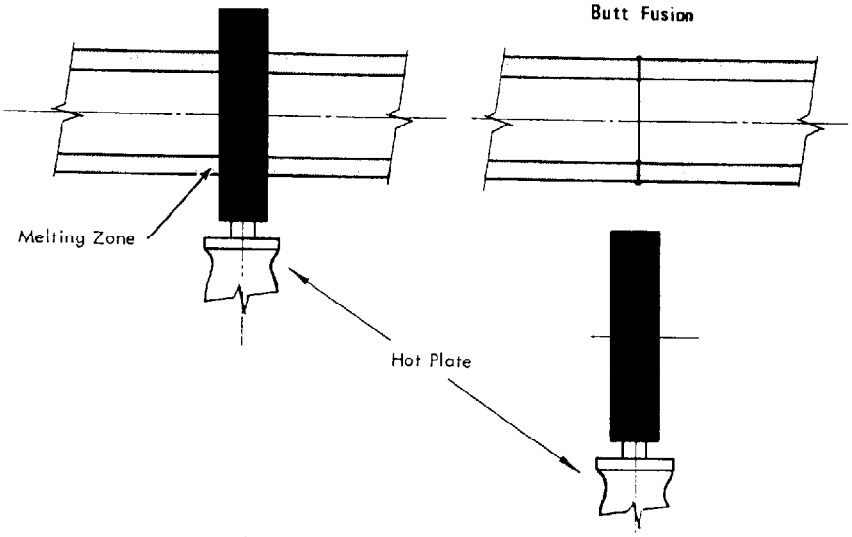

FIG. 2 Typical Butt Fusion Operation

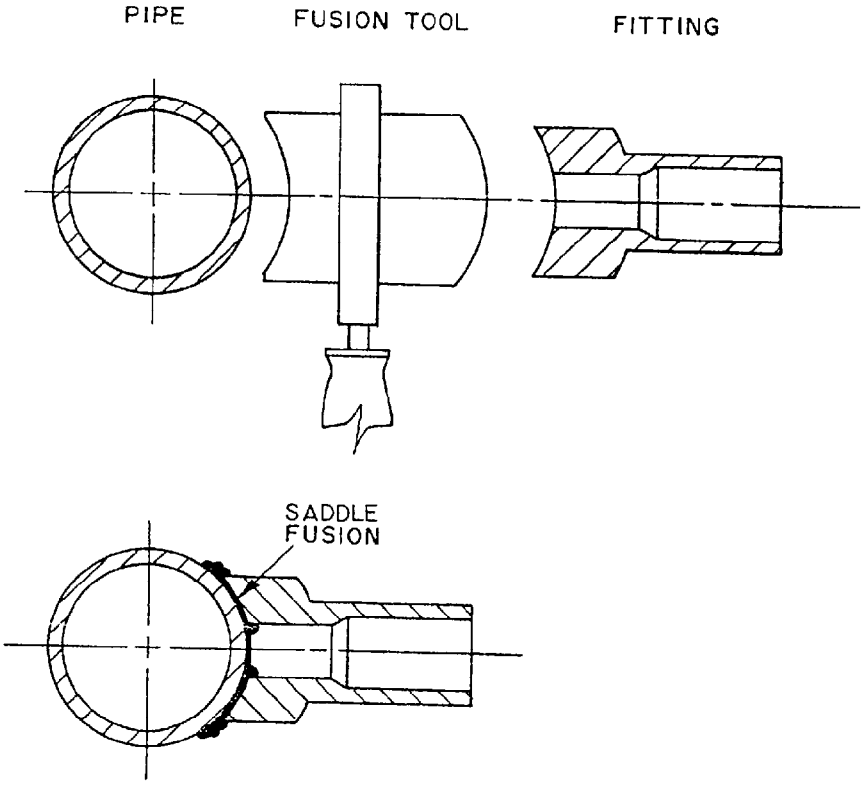

FIG. 3 Saddle Fusion

affected by deteriorated non-stick surfaces. Spray-on chemicals, such as non-stick lubricants or oils shall not be applied to heating iron surfaces as they will contaminate the joint.

6.3 *Temperature Indicator*—Heating tools shall be equipped with a thermometer or other built-in temperature indicating device. This device indicates the internal temperature of the heating iron which is usually higher than temperature of the fusion surfaces. Use a pyrometer periodically to verify the temperature of the tool surfaces within the pipe or fitting contact area. Select multiple checkpoints to ensure uniform surface temperature.

NOTE 2—A significant temperature variation, that is, cold spots, on the fusion surfaces may indicate a faulty heating iron which may need to be serviced before it can be used.

7. Procedure 1—Socket Fusion

Wed Feb 02 01:53:03 2005

cordance with Specification F 1056 should be used for joining polyethylene pipe, tubing, and fittings.

7.1.1 *Heating Tool*—In order to obtain a proper melt, it is necessary for a uniform temperature to be maintained across the heating surface. Therefore, gas-fired tools are generally restricted to use with pipe sizes of 2 in. IPS (63 mm) or less.

7.1.2 *Heating Tool Faces*—Consisting of two parts, a male end for the interior socket surface and a female end for the exterior pipe surface. Both parts shall be made to such tolerances as to cause an interference fit.

7.1.3 *Alignment Jig*—The alignment jig is an optional tool which consists of two sets of devices holding the components in alignment to each other. One set of holding devices is fixed, and the other allows longitudinal movement for making the joint.

7.1.4 *Rounding Clamps*, (cold ring) to maintain roundness of the pipe and control the depth of pipe insertion into the socket during the joining operation.

7.1.5 *Depth Gage*, for proper positioning of the rounding clamp.

7.1.6 *Chamfering Tool*, to bevel the end of the pipe.

NOTE 3—The depth gage and chamfering tool may be combined into a single tool.

7.1.7 *Tubing Cutter*, to obtain a square end cut on the pipe.

7.1.8 *Fitting Puller*, an optional tool to assist in the removal of the fitting from the heating tool and to hold the fitting during assembly.

7.2 *Procedure:*

7.2.1 Attach the proper size heater faces to the heating tool, and heat the tool to the fusion temperature for the material.

7.2.2 Cut the pipe end squarely, and clean the pipe end and fitting, both inside and outside, by wiping with a clean, dry, oil-free, lint-free cloth.

7.2.3 Chamfer the outside edge of the pipe end slightly and fix the rounding clamp about the pipe as determined from the depth gage.

NOTE 4—Chamfering may not be required by some procedures or some fusion tools. Pipe sizes 1 in. (25.4 mm) and smaller are not usually chamfered, regardless of tooling design.

NOTE 5—Some recommend using a 50 to 60-grit emery or garnet cloth to roughen the outside of the pipe and inside of the fitting as a means of minimizing any possible skin interface when making the fusion. Sandpaper is not recommended for this purpose, as it might disintegrate and contaminate the joint interface. If roughening is performed, first clean the surfaces before roughening. Clean dust and particles from the roughened surfaces afterwards by wiping with a clean, dry, oil-free, lint-free cloth.

7.2.4 Bring the preheated tool faces into contact with the outside surface of the end of the pipe and the inside surface of the socket.

7.2.5 Heat the pipe end and the fitting socket for the time required to obtain a proper melt. Proper melt is a function of material, time, tool temperature, and the size of the parts. Pipe and fittings of larger diameters require more time to reach the proper melt consistency than those of smaller diameters. Underheated or overheated materials will not form a good bond.

7.2.6 At the end of the heating time, simultaneously remove the pipe and fitting straight out from the tool, using a snap action. Immediately insert the pipe straight into the socket of the fitting so the rounding clamp is flush against the end of the fitting socket. Hold or block the joint in place until the melts of the mating surfaces have solidified. The exact cooling time depends on the size of the pipe and the material being fused.

7.2.7 Remove the rounding clamp, and inspect the melt pattern at the end of the socket for a complete impression of the rounding clamp in the melt surface. There shall no gaps, voids, or unbonded areas. Clean the heating tool of any residual material using a wood stick or a clean, dry, oil-free, lint-free, non-synthetic cloth. Take care not to damage the heating surfaces. Plastic left on the tool tends to char when reheated, causing a loss of heater efficiency and joint contamination.

7.2.8 Allow for extremes in weather when making field joints. Heating times, operation of alignment jig, dimensional changes, and the like, are affected by extreme conditions.

7.3 *Testing*—Evaluate sample joints in order to verify the skill and knowledge of the fusion operator. Cut joints into straps, (see Fig. 4) and visually examine and test for bond continuity and strength. Bending, peeling, and elongation tests are useful for this purpose.

8. Procedure 2—Butt Fusion

8.1 *Apparatus:*

8.1.1 *Heating Tool*—The heating tool shall have sufficient area to adequately cover the ends of the size of pipe to be joined.

8.1.2 *Alignment Jig*—The alignment jig is three basic parts: (*1*) a stationary clamping fixture and a movable clamping fixture for holding each of the two parts to be fused in alignment; (*2*) a facer for simultaneously preparing the ends of the parts to be joined (Note 6); and (*3*) appropriate adapters for different pipe sizes. Alignment jigs are manually or hydraulically powered.

NOTE 6—A facer is a rotating cutting device used to square-off the pipe or fitting ends to obtain properly mating fusion surfaces.

8.2 *Procedure:*

8.2.1 Bring the heater plate surfaces to proper temperature.

8.2.2 Clean the inside and outside of the components (pipe or pipe and fitting) to be joined. Remove all foreign matter from the surface of the component where it will be clamped in the alignment jig.

8.2.3 Align each component with its alignment jig clamp, and close the clamp. Check component to component alignment, adjust as needed, and face off the ends.

8.2.3.1 Take care when placing pipe or fittings in the alignment jig. Pipes shall be aligned before the alignment clamp is closed; however, do not force the pipe into alignment by pushing it against the side of an open alignment jig clamp.

8.2.4 Bring the piping components together and check for high-low alignment, and out-of-roundness. Adjust as required. Re-face after adjustment. The ends of the piping components shall be square to each other around their full circumference.

8.2.5 Place the heater plate between the component ends, and move the component ends against the heater plate with sufficient force to ensure complete circumferential contact against the heater plate. Hold the components against the heater plate briefly, using limited force to ensure that proper contact with the plate has been made. Release the force, but hold the components against the heater plate until an appropriately sized bead of molten plastic develops circumferentially around each component end as a result of the thermal expansion of the material. Do not push the components into the heater plate as the melting progresses.

8.2.6 Move the melted component ends away from the heater plate, and remove the heater plate. Then immediately bring the melted ends together with enough force to roll both component melt beads over to the pipe surface around the entire circumference of the joint. When the bead touches the pipe surface, stop moving the component ends together, but do not release the force. Hold the force on the joint until the joint has cooled.

8.2.6.1 Do not use excessive or insufficient force. If the components are brought together with too much force, all molten material may be pushed out of the joint and cold material brought into contact forming a "cold" joint. If too little force is used, only the melt in the beads may be fused together and, as the molten material in the joint cools and contracts, voids or non-fused areas may be formed. If the softened material sticks to the heater plate, discontinue the joining procedure. Clean the heater plate, re-square the component ends, and repeat the process from the beginning (8.2.2).

8.2.7 Allow the assembly to stand at least until cool before removing the clamps or other aligning device (Note 7). Do not subject the joint to high stress until it has cooled to less than approximately 130°F. Do not apply internal pressure until the joint and surrounding material have reached ambient air temperature.

NOTE 7—The joint is usually cool enough to remove from the alignment jig if a bare hand can be held against the beads without discomfort (less than approximately 130°F). Further cooling is recommended prior to ditching the pipe.

8.2.8 Visually inspect the joint against recommended appearance guidelines. The beads should be uniformly shaped and sized all around the joint.

8.3 *Testing*—Evaluate sample joints to verify the skill and knowledge of the fusion operator. Butt-fusion joints can be nondestructively examined using ultrasonic equipment to detect voids or other discontinuities. For destructive tests, cut joints into straps (see Fig. 4), visually examine, and test for bond continuity and strength. Tests that have been found useful for this purpose include inside face bend, outside face bend, tensile elongation, torque, and impact. Quantifiable data may be obtained by the use of laboratory procedures and comparing data against that from control samples.

9. Procedure 3—Saddle Fusion

9.1 *Apparatus:*

9.1.1 *Heating Tool Faces*—The faces are matched sets, by pipe size, of concave and convex blocks which bolt or clamp onto a flat or round core heater.

9.1.2 *Alignment Jigs*—Various types of alignment jigs are available. Alignment jigs provide a means to mount the alignment jig on the pipe, hold the fitting and align it to the pipe, and move the fitting towards and away from the pipe. Alignment jigs are used for saddle fusions for optimum results and are required for certain materials.

NOTE 8—Some materials may be saddle fused using a hand-stab procedure. Consult the manufacturer for a hand-stab procedure.

9.2 *Procedure:*

9.2.1 Bring heater plate and faces to proper temperature.

9.2.2 Clean the mating surfaces of the pipe and the concave surface of the fitting base and roughen the mating surfaces. Emery or garnet cloth of 50 to 60 grit is used to remove the tough outer surface skin. It is essential to remove the surface skin completely without altering the contours of the mating surfaces and to keep the surface clean. Remove dust and particles from the surface after roughing with a clean, dry, oil-free, lint-free cloth.

9.2.3 Install the alignment jig on the pipe. For smaller pipe sizes, install a bolster plate under the pipe to provide additional support.

9.2.4 Install the fitting in the alignment jig. Press the fitting against the pipe to align the fitting base to the pipe, then secure the fitting in the alignment jig.

9.2.5 Place the heater on the pipe and press the fitting against the heater to obtain a melt on both the pipe and the fitting.

Copyright by the ASTM International
Wed Feb 02 01:53:04 2005

NOTE 9—When saddle fittings are fused to pipes that are under pressure, it is important that the surface melt be obtained quickly without too much heat penetration. Otherwise, the pipe may rupture from internal pressure. Consult the manufacturer for specific recommendations for fusing saddle fittings to pipe under pressure.

9.2.6 When a proper melt is achieved, remove the heater, quickly examine the pipe and fitting to ensure proper melt patterns, and immediately place the fitting on the pipe. Hold in place while exerting suitable force for the specified cooling time.

NOTE 10—If a suitable melt pattern has not been achieved, do not reheat; however, continue with the fusion and apply the fitting to the pipe. When the joint has cooled, remove the alignment jig, cut off the top of the fitting to prevent use, and start over at another location.

9.3 Visually inspect the joint against recommended visual inspection guidelines.

9.4 *Testing*—Evaluate sample joints to verify the skill and knowledge of the fusion operator. Cut joints into straps (see Fig. 4), visually examine, and test for bond continuity and strength. See Practice F 905 for methods for evaluating the quality of fusion joints.

10.1 butt fusion; fitting; heat fusion; joining; pipe; polybutylene; polyethylene; polyolefin; polypropylene; saddle fusion; socket fusion

ANNEX

(Mandatory Information)

A1. COLD WEATHER PROCEDURES

A1.1 *Cold Weather Handling*—Pipe should be inspected for damage. Polyolefin pipes have reduced impact resistance in sub-freezing conditions. Avoid dropping pipe in sub-freezing conditions. When handling coiled pipe at temperatures below 40°F, it is helpful to uncoil the pipe prior to installation and let it straighten out. Gradually uncoil the pipe and cover it with dirt at intervals to keep it from recoiling. Always use caution when cutting the straps on coils of pipe because the outside end of a coil may spring out when the strapping is removed.

A1.2 *Preparation for Socket, Saddle, and Butt Fusion Joining:*

A1.2.1 *Wind and Precipitation*—The heating tool should be shielded in an insulated container to prevent excessive heat loss. Shield the pipe fusion area and fusion tools from wind, snow, and rain by using a canopy or similar device.

A1.2.2 *Pipe and Fitting Surface Preparation*—The pipe and fitting surfaces to be "joined" or held in clamps should be dry and clean and free of ice, frost, snow, dirt, and other contamination. Regular procedures for preparation of surfaces to be joined, such as facing for butt fusion and roughening for saddle fusion should be emphasized. After preparation, the surfaces should be protected from contamination until joined. Contamination of the area to be fused will likely cause incomplete fusion. Frost and ice on the surfaces of the pipe to be clamped in either a cold ring or alignment jigs may cause slippage during fusion. Inspect coiled pipe to see if it has flattened during storage which could cause incomplete melt pattern or poor fusion. It may be necessary to remove several inches at the pipe ends to eliminate such distortion. Pipe may have a slight toe-in or reduced diameter for several inches at the end of the pipe. The toe-in may need to be removed before butt fusing to a freshly cut pipe end, or to a fitting.

A1.2.3 *Heating*—Work quickly once pipe and fitting have been separated from the heating tool, so that melt heat loss is minimized, but still take time (no more than 3 s) to inspect both melt patterns. Keep the heater dry at all times. Check the temperature of the heating tool regularly with a pyrometer. Keep the heating tool in an insulated container between fusions.

A1.3 *Socket Fusion:*

A1.3.1 *Pipe Outside Diameter*—Pipe outside diameter contracts when cold. This results in loose or slipping cold rings. For best results, clamp one cold ring in its normal position adjacent to the depth gage. Place shim material (that is, piece of paper or rag, etc.) around the inside diameter of a second rounding ring and clamp this cold ring directly behind the first cold ring to prevent slippage. The first cold ring allows the pipe adjacent to the heated pipe to expand to its normal diameter during the heating cycle.

A1.3.2 *Fitting Condition*—If possible, store socket fittings at a warm temperature, such as in a truck cab, prior to use. This will make it easier to place the fitting on the heating tool because fittings contract when cold.

A1.3.3 *Heating*—At colder temperatures the pipe and fitting contract, thus the pipe slips more easily into the heating tool. At very cold outdoor temperatures (particularly with 2, 3, and 4 in. IPS pipe), the pipe may barely contact the heating surface. Longer heating cycles are used so that the pipe first expands (from tool heat) to properly contact the heating tool, then develops complete melt. The length of cycle necessary to obtain a complete melt pattern will depend not only on the outdoor (pipe) temperature but wind conditions and operator variation. Avoid cycles in excess of that required to achieve a good melt pattern. To determine the proper cycle time for any particular condition, make a melt pattern on a scrap piece of pipe, using the heating cycle as instructed by the pipe manufacturer. If the pattern is incomplete (be sure rounding rings are being used), try a 3-s longer cycle on a fresh (cold) end of pipe. If the melt pattern is still not completely around the pipe end, add an additional 3 s and repeat the procedure. Completeness of melt pattern is the key. Keep the heater dry at all times. Check the temperature of the heating tool regularly and keep the heating tool in an insulated container between fusions.

A1.4 *Butt Fusion:*

A1.4.1 *Joining*—The heating cycles shall be as recom-

Copyright by the ASTM International
Wed Feb 02 01:53:04 2005

mended by the pipe manufacturer. It will take longer to develop the initial melt bead completely around the pipe ends. Do not increase pressure during heating. When proper melt bead has been obtained, the pipe and heater shall be separated in a rapid, snap-like motion. The melted surfaces shall then be joined immediately in one smooth motion so as to minimize cooling of the melted pipe ends.

A1.5 *Saddle Fusion:*

A1.5.1 *Surface Preparations*—Regular procedures for roughening the surfaces to be fused on the pipe and the fitting should be emphasized. After the surfaces have been prepared, particular care should be taken to protect against contamination.

A1.5.2 *Heating Time*—Make a trial melt pattern on a scrap piece of pipe. A clean, dry piece of wood is used to push the heating tool against the pipe. If the melt pattern is incomplete, add 3 s to the cycle time and make another trial melt pattern on another section of cold pipe. If the pattern is still incomplete, continue 3-s additions on a fresh section of cold pipe until a complete melt pattern is attained. Use this heating cycle for fusions during prevailing conditions. Regardless of the weather or the type of tools used, the important point to remember is that complete and even melt must occur on the fitting and the pipe in order to produce a good fusion joint. This requires pipe preparation to make it clean, straight, round, and well supported.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: D 2661 – 01

An American National Standard

Standard Specification for Acrylonitrile-Butadiene-Styrene (ABS) Schedule 40 Plastic Drain, Waste, and Vent Pipe and Fittings[1]

This standard is issued under the fixed designation D 2661; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers fittings and single and coextruded acrylonitrile-butadiene-styrene (ABS) plastic drain, waste, and vent pipe (DWV) made to Schedule 40 iron pipe sizes (IPS). Plastic which does not meet the material requirements specified in Section 5 is excluded from single layer and all coextruded layers.

1.2 Specification for fittings for use with pipe meeting the requirements of this specification are given in Annex A1.

1.3 Acrylonitrile-butadiene-styrene plastic, which does not meet the definition of virgin ABS plastic as given in 3.2.2, is excluded, as performance of plastic other than those defined as virgin was not determined. ABS rework plastic, which meets the requirements of rework plastic as given in 5.3, is acceptable.

1.4 Reprocessed plastic or recycled plastic as defined in Terminology D 883 is excluded.

1.5 Recommendations for storage, joining, and installation are provided in Appendix X1, Appendix X2, and Appendix X3, respectively.

1.6 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.7 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

2.3 *Military Standard:*

MIL-STD-129 Marking for Shipment and Storage[6]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise specified. The abbreviation for acrylonitrile-butadiene-styrene is ABS.

3.1.1 *coextruded pipe*—pipe consisting of two or more concentric layers of material bonded together in processing by any combination of temperature, pressure, grafting, crosslinking, or adhesion.

3.1.2 *coextrusion*—a process whereby two or more heated or unheated plastic material streams forced through one or more shaping orifice(s) become one continuously formed piece.

3.1.3 *room temperature*—a temperature in the range from 68 to 85 ± 3.6°F (20 to 30 ± 2°C).

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *lot*—a lot shall consist of all pipe of the same size produced from one extrusion line during one designated 24-h period.

3.2.2 *recycled plastic*—a plastic prepared from discarded articles that have been cleaned and reground.

3.2.3 *reprocessed plastic*—a thermoplastic usually prepared from melt processed scrap or reject parts by a plastics processor, or from nonstandard or nonuniform virgin material.

3.2.4 *virgin ABS plastic*—plastic in the form of pellets, granules, powder, floc, or liquid that has not been subjected to use or processing other than that required for its initial manufacture.

4. Classification

4.1 The requirements of this specification are intended to provide pipe suitable for the drainage and venting of sewage and certain other liquid wastes.

NOTE 1—Industrial waste disposal lines should be installed only with the specific approval of the cognizant building code authority since chemicals not commonly found in drains and sewers and temperatures in excess of 180°F (82°C) may be encountered.

5. Materials

5.1 *Material Specification*—Virgin black ABS plastic shall conform to the requirements prescribed in Specification D 3965 with a cell classification of 4-2-2-2-2. The form of the material shall be as agreed upon between the seller and the purchaser in accordance with Specification D 3965.

5.2 The ABS plastic shall conform to the following requirements:

5.2.1 *Acrylonitrile-Butadiene-Styrene (ABS) Plastic*—Plastic containing polymers or blends of polymers shall contain a minimum of 15 % acrylonitrile, 6 % butadiene, and 15 % styrene or substituted styrene, or both. ABS plastic shall contain no more than 10 % of other monomeric or polymeric components plus other necessary compounding ingredients.

5.3 *Rework Material*—The manufacturer shall use only his own clean pipe or fitting rework material conforming with these cell class requirements. The pipe or fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *General*—The pipe and fittings shall be homogeneous throughout and free of visible cracks, holes, foreign inclusions, or other injurious defects. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

6.1.1 The requirements in this section are intended only for use as quality control tests, not as simulated service tests.

6.2 *Dimensions and Tolerances*:

6.2.1 *Outside Diameter*—The outside diameter and tolerances shall meet the requirements of Table 1 when measured in accordance with Test Method D 2122. The tolerance for out-of-roundness shall apply to pipe prior to shipment.

6.2.2 *Wall Thickness*—The wall thickness and tolerances shall meet the requirements of Table 2 when measured in accordance with Test Method D 2122.

6.2.3 *Length*—The pipe shall be in either 10 or 20-ft (3.05 or 6.1-m) lengths, unless otherwise specified. The allowable tolerance on length shall be +½, –0 in. (+12, –0 mm).

6.3 *Performance Requirements*:

6.3.1 *Pipe Stiffness*— The minimum pipe stiffness values at 5 % deflection when measured in accordance with Test Method D 2412, shall equal or exceed the values in Table 3. The rate of crosshead motion shall be 0.20 to 0.25 in./min (5.1 to 6.3 mm/min). Three specimens shall be tested. If all three meet this requirement, the sample meets this requirement. If one or two fail, additional testing shall be conducted in accordance with 6.3.1.1. If all three fail, the sample does not meet the requirement.

6.3.1.1 *Pipe Stiffness and Lower Confidence Limit*—In the event that one or two of the specimens tested in 6.3.1 fail to meet the minimum requirement, the average pipe stiffness of eleven specimens shall meet or exceed the minimum requirement given in Table 3. The 99 % lower confidence limit (LCL) shall be within 15 % of the average value. The LCL shall be calculated using the Student's "*t*" distribution, with *N*-1 degrees of freedom, where *N* is the number of specimens. The critical *t* value shall be used to at least three significant digits. Alternatively, if the LCL exceeds the minimum PS requirement in Table 3, but is not within 15 % of the average, the sample meets the requirements of the Pipe Stiffness testing. The eleven

TABLE 1 Outside Diameters and Tolerances for ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe

Nominal Pipe Size, in.	Outside Diameter		
	Average, in. (mm)	Tolerance on Average, in. (mm)	Out-of-Roundness Maximum Diameter Minus Minimum Diameter, in. (mm)[A]

TABLE 2 Wall Thickness and Tolerance for ABS Schedule 40 Drain, Waste, and Vent Pipe

Nominal Pipe Size, in.	Wall Thickness[A]	
	Minimum Wall, in. (mm)	Tolerance, in. (mm)
1¼	0.140 (3.56)	+0.015 (+0.38) −0.000 (−0.00)
1½	0.145 (3.68)	+0.015 (+0.38) −0.000 (−0.00)
2	0.154 (3.91)	+0.015 (+0.38) −0.000 (−0.00)
3	0.216 (5.42)	+0.020 (+0.51) −0.000 (−0.00)
4	0.237 (6.02)	+0.024 (+0.61) −0.000 (−0.00)
6	0.280 (7.11)	+0.030 (+0.76) −0.000 (−0.00)

[A]The minimum is the lowest wall thickness of the pipe at any cross section.

TABLE 3 Pipe Stiffness of ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe

Nominal Pipe Size, in.	Minimum Pipe Stiffness at 5 % Deflection	
	psi	(MPa)
1¼	870	(6.00)
1½	630	(4.34)
2	370	(2.55)
3	320	(2.20)
4	190	(1.31)
6	95	(0.65)

specimens include the three tested under 6.3.1, and an additional eight with rotation by 35°, as specified in Test Method D 2412, continuing throughout the remaining specimens.

6.3.1.2 The LCL based on testing eleven specimens is calculated as follows:

$$\text{LCL} = (\text{avg PS}) - \{2.76(\text{std. dev.})/\sqrt{(N)}\} \quad (1)$$

where:

$$(\text{avg PS}) = [\Sigma(PS_i)]/(11)$$

$$(\text{std. dev.}) = \left[\frac{\Sigma PS^2 - (\Sigma PS)^2/N}{N-1}\right]^{1/2}$$

$$N = 11.$$

6.3.1.3 The 15 % requirement is calculated as follows:

$$(Avg - LCL)/(Avg) \times 100 \leq 15\ \% \quad (2)$$

NOTE 2—For quality control testing, a single specimen may be used with the thinnest wall at the top.

NOTE 3—The 5 % deflection criteria is arbitrarily selected for testing convenience. It should not be considered as a limitation with respect to in-use deflection. The engineer is responsible for establishing the acceptable deflection limit.

NOTE 4—The strength and load-carrying capabilities of plastic pipe are measured and reported as pipe stiffness, which is determined in accordance with Test Method D 2412. The term "crush strength" is not applicable to plastic piping because the values obtained can be significantly different, depending on the bedding, loading, or testing technique used, and because the term derives from rigid pipe and refers to its ultimate strength at rupture.

6.3.2 *Pipe Flattening*—There shall be no evidence of rupture when pipe is deflected 40% of the initial inside diameter when tested in accordance with Test Method D 2412. The rate of head approach shall be 0.20 to 0.25 in./min (5.1 to 6.3 mm/min). Three specimens shall be tested. All shall meet the requirements. Failure shall be a crack or break extending entirely through the pipe wall visible to the unaided eye.

6.3.3 *Impact Resistance*—The minimum impact resistance, when tested at the time of manufacture, shall comply with Table 4. Test in accordance with Test Method D 2444 using Tup B and Holder B. Use a 30-lb (13.6 kg) tup for testing all pipe sizes.

6.3.3.1 Test 10 specimens. When 9 or 10 specimens pass, accept the lot. When 2 or more specimens fail, test 10 additional specimens. When 17 of 20 specimens tested pass, accept the lot. When 4 or more of 20 specimens fail, test 20 additional specimens. When 32 of 40 specimens pass, accept the lot. When 9 or more of 40 specimens fail, the lot does not meet the requirements of this specification.

6.3.3.2 Failure of the test specimen shall be shattering or any crack or break extending entirely through the pipe wall and visible to the unaided eye.

6.4 *Coextruded Pipe*:

6.4.1 *Thickness of Outer Layer*—For pipe produced by the coextrusion process, that is, pipe containing two or more concentric layers, the outer layer shall be at least 0.020 in. (0.50 mm) thick and shall contain pigments or screening agents to provide protection against UV radiation.

6.4.2 *Bond*—For pipe produced by the coextrusion process, that is, pipe containing two or more concentric layers, the bond between the layers shall be strong and uniform. It shall not be possible to separate any two layers with a probe or point of a knife blade so that the layers separate cleanly so the probe or knife blade moves freely between the layers. Nor shall separation of bond occur between layers during testing performed under the requirements of this specification.

6.5 *Other Requirements*:

6.5.1 *Inspection*—Before installation the pipe shall be inspected. Pipe which does not meet the requirements of this specification shall be returned to the seller.

6.5.2 *Joining*—ABS schedule 40 drain, waste, and vent (DWV) are joined using molded fittings meeting the requirements of Annex A1 of this specification.

6.5.3 *Solvent Cement*—In the assembly of solvent cement joints, the safety requirements of Practice F 402 shall be

TABLE 4 Impact Resistance of ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe

Nominal Pipe Size, in.	Minimum Impact Resistance, ft·lbf (J)	
	At 73°F	(23°C)
1¼	20	(27)
1½	30	(41)
2	40	(54)
3	60	(81)
4	60	(81)
6	100	(136)

Copyright by the ASTM International
Wed Feb 02 01:53:37 2005

followed using solvent cement meeting the requirements of Specification D 2235.

7. Sampling and Conditioning

7.1 *Sampling*—For the purpose of testing, the lot shall consist of all pipe produced of one size, from one extrusion line, during one designated 24-h period. The number of specimens designated for each test shall be taken from pipe selected at random from each lot in accordance with the random sampling plan of Practice D 1898.

NOTE 5—Refer to Practices E 105 and E 122.

7.2 *Number of Tests for Quality Control*—When evaluating the product against this specification, the following minimum number of specimens shall be tested for each lot.

7.2.1 *Outside Diameter*—One specimen per extrusion line.

7.2.2 *Wall Thickness*—One specimen per extrusion line.

7.2.3 *Length*—One specimen per extrusion line.

7.2.4 *Pipe Stiffness*—A minimum of three specimens per extrusion line. (See Note 2.)

7.2.5 *Pipe Flattening*—A minimum of three specimens per extrusion line.

7.2.6 *Impact Strength*—A minimum of ten specimens and a maximum of 40.

7.2.7 *Bond*—One specimen for each extrusion line.

7.3 *Conditioning*:

7.3.1 For referee purposes, condition the specimens prior to test at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity in accordance with Practice D 618, Procedure A.

7.3.2 For routine quality control testing, condition the specimens at the temperature and humidity of the manufacturers testing facility for not less than 1 h or until the specimens are at room temperature.

7.4 *Test Conditions*:

7.4.1 For referee purposes, conduct tests in the standard laboratory atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity.

7.4.2 For routine quality control testing, conduct tests at the room temperature and humidity of the manufacturers testing area.

7.5 *Test Methods*—Use only the specified ASTM test methods.

8. Retest and Rejection

8.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and the seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If, upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

9. Product Marking

9.1 *Quality of Marking*—The markings shall be applied to the pipe in such a manner that they remain legible (easily read) after installation and inspection.

9.2 *Content of Marking*—The pipe shall be marked on two sides 180° apart at least every 2 ft (0.6 m) in letters not less than 3/16 in. (5 mm) high, in a contrasting color with the following information:

9.2.1 The manufacturer's name (or trademark).

9.2.2 The designation "ASTM D 2661".

9.2.3 Nominal pipe size (for example, 2 in. (51 mm)).

9.2.4 The manufacturer's code for resin manufacturer, lot number, and date of manufacture.

9.2.5 *Single Extrusion Pipe*—The pipe produced by single extrusion process shall be marked "ABS DWV".

9.2.6 *Coextruded Pipe*—The pipe produced by the coextrusion process shall be marked "COEXTRUDED ABS DWV".

10. Quality Assurance

10.1 When the product is marked with this designation, D 2661, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

11. Keywords

11.1 ABS; DWV; fittings; pipe; plastic; Schedule 40; thermoplastic

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to federal/military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the material shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor

Copyright by the ASTM International
Wed Feb 02 01:53:37 2005

Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S1.1—The inclusion of U.S. Federal Government procurement requirements should not be construed as an indication that the U.S. Federal Government uses or endorses the products described in this specification.

ANNEX

(Mandatory Information)

A1. ABS FITTINGS

A1.1 The pattern, dimension, and laying length of fittings shall meet the requirements of Specification D 3311 and Table A1.1 when determined in accordance with Test Method D 2122.

A1.2 Fittings produced by any molding process shall be made of virgin black ABS plastic which shall conform to the requirements prescribed in Specification D 3965 with a cell classification of 3-2-2-2-2. The form of the material shall be as agreed upon between the seller and the purchaser in accordance with Specification D 3965.

A1.3 *Rework Material*—The manufacturer shall use only his own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

A1.4 The spigot dimensions of the fittings shall meet the requirements of Table 1 and Table 2.

A1.5 For all fittings having taper pipe threads, threads shall conform to and be gaged in accordance with Specification F 1498.

A1.6 Individual fittings unassembled shall withstand a minimum load of 750 lbf/ft (11 kN/m) of centerline length without visible evidence of failure when tested in accordance with Test Method D 2412.

A1.7 Individual fittings unassembled shall meet a minimum impact of 20 ft·lbf (27 J) when tested in accordance with Test Method D 2444 at 73°F (23°C) using a 12-lb (5-kg) Tup C and Holder B. Test inline couplings cemented to short pieces of pipe and allow to dry for at least 24 h.

A1.8 Solvent cement meeting the requirements of Specification D 2235 shall be used to join pipe and fittings.

A1.9 Fittings shall be marked on the body or hub with the manufacturer's name or trademark, and the symbol "ABS".

4	4.515	+0.010 −0.005	0.030	4.495	+0.005 −0.010	0.030	1.750	0.250	0.225	4.907	1.281
6	6.647	±0.011	0.060	6.614	±0.011	0.060	3.000	0.281	0.253	7.203	1.500

[A] Measure at the intersection of pipe stop cone with socket cylinder.
[B] Measure from socket entrance to intersection of pipe stop cone with socket cylinder.
[C] The average wall thickness is the minimum wall thickness plus the opposite wall thickness divided by 2. The average shall equal or exceed that shown in Table A1.1. The minimum wall thickness, due to core shift, shall equal or exceed the value shown in the table. The minimum wall thickness is determined by allowing a 10 % variation due to core shift.

APPENDIXES

(Nonmandatory Information)

X1. STORAGE

X1.1 *Outside Storage*—Plastic pipe should be stored on a flat surface or supported in a manner that will prevent sagging or bending. Do not store pipe in direct sunlight forlong periods.

X1.2 Inventories of plastic pipe should be used on a first-in, first-out basis.

Copyright by the ASTM International
Wed Feb 02 01:53:38 2005

X2. JOINING

X2.1 *Field Inspection*—Prior to use, all pipe should be carefully inspected for cuts, gouges, deep scratches, damaged ends, or other major imperfections. Defective pipe should be rejected or the damaged sections should be cut out.

X2.2 *Pipe Fit*—Pipe is manufactured to close tolerances to ensure satisfactory "interference" fit between the pipe and the fittings socket during assembly. Use only combinations of pipe and fittings that give interference fits. Pipe that is a loose fit in the socket may not properly bond. The allowable tolerance assures a forced fit and when solvent cement is applied, the pipe and fitting will readily mate, thus assuring proper adhesion. The pipe should enter the dry fitting socket to between one half and two thirds of the fitting socket depth.

X2.3 *Cutting*—Pipe can be easily cut with an ordinary hacksaw or carpenter's saw. Fine-tooth blades with little or no set should be used for best results. The pipe should be cut square and all burrs removed with a sharp knife, a fine-tooth file, or other suitable tool such as chamfering tool or reamer. A miter box is recommended to ensure square cut ends. Standard steel pipe or tubing cutters are not recommended for cutting ABS pipe since they may cause excessive heat and pressure, that can result in cracked or irregular pipe ends. There are special plastic pipe cutters available with extra wide rollers and thin cutting wheels that have been especially designed for cutting plastic pipe, and their use is recommended.

X2.4 *Cleaning*—Remove burrs from inside and outside pipe edges. Wipe off all dust, dirt, and moisture from surfaces to be cemented with a clean dry rag or a paper towel. At no time should pipe or fittings be assembled that are wet or damp. Pipe and fittings must be dry before assembly to obtain good joints.

X2.5 *Safety Requirements for Solvent Cement and Primers*—Follow Practice F 402.

X2.6 *Solvent Cement*—Use only solvent cement designed for ABS. Use a solvent cement meeting the requirements of Specification D 2235.

X2.6.1 *Application of Cement*—Using the applicator supplied with the can of solvent cement, or a brush or roll with a width of about one half the pipe diameter for pipe sizes above 2 in. (51 mm), apply a moderate, even coating of cement in the fitting socket to cover only the surfaces to be joined. Heavy or excessive application of solvent cement may become an obstruction in the pipe and prevent satisfactory joining. Quickly apply a heavy coat of solvent cement to the outside of the pipe. Make sure that the coated distance on the pipe is equal to the depth of the fitting socket.

X2.7 *Assembly*—Make the joint as quickly as possible after application of the solvent cement and before the solvent cement dries. Should the solvent cement dry partially before the joint is made up, reapply solvent cement before assembling. Insert the pipe into the fitting socket, making sure that the pipe is inserted to the full depth of the fitting socket. Hold the joint together firmly for about 30 s for small diameter pipe and 60 s for diameters above 6 in. (152 mm) to avoid push-out. Remove excessive solvent cement from the exterior of the joint with a clean, dry cloth.

X2.8 *Set Time*—Do not attempt to disturb the pipe and fitting joint until after the solvent cement has set, or damage to the joint and loss of fit may result. Reasonable handling of assembly is permissible within 2 min after joining. Allow 15 min for the joint to develop good handling strength and the joint will withstand the stresses of normal installation. A badly misaligned installation will cause excessive stresses in the joint, pipe, and fittings and constitutes a plumbing code violation and should be avoided. The recommendation of the solvent cement manufacturer should be followed for best results.

X2.9 *Cure Time*—Joint strength development is very rapid during periods of high ambient temperatures, low relative humidity, and using interference-type fittings. Joint strength development is not as rapid during periods of low ambient temperatures, high relative humidity, and using loose fits. Therefore, the recommendations of the solvent cement manufacturer should be followed for best results prior to leak testing.

X3. INSTALLATION

X3.1 *Underground Installation*—Underground installations of pipe shall be in accordance with the Plumbing Code, except maximum aggregate size shall be limited to ½ in. (13 mm) for angular and ¾ in. (19 mm) for rounded particles. For special conditions Design Engineers may wish to consult Practice D 2321.

X3.2 *DWV Installation*—Pipe should be installed in conformance with governing building codes. In areas not governed by codes, pipe should be installed in accordance with accepted engineering practices.

X3.3 *Installation Under Freezing Conditions*—Plastic pipe has decreased resistance to impact under freezing conditions. Increased care should be exercised if installation is likely to occur under these conditions, particularly during handling, transportation, installation, and backfilling. Where possible, installation should be avoided during freezing conditions. Allowance shall be made for expansion that will occur when the temperature of the pipe is raised.

X3.4 *Alignment and Grade*—Align all piping system components properly without strain. Do not bend or pull pipe into

Copyright by the ASTM International
Wed Feb 02 01:53:38 2005

position after being solvent cemented. The grade of horizontal drainage and vent piping shall be as specified in the applicable code.

X3.5 *Supports and Spacing*—Hangers and straps should not compress, distort, cut, or abrade the piping and should allow free movement of pipe. Support horizontal piping at intervals of not more than 4 ft (1.2 m) at end of branches and at changes of direction or elevation. Supports should allow free movement. Maintain vertical piping in straight alignment with supports at each floor level or at 10-ft (3.1-m) intervals, whichever is less. Support trap arms in excess of 3 ft (0.9 m) in length as close as possible to the trap. Securely fasten closed flanges with corrosion-resistant fasteners to the floor with the top surface ¼ in. (6.4 mm) above the finish floor level. Stabilize closet bends or stubs against all horizontal or vertical movement. Protect pipe exposed to damage by sharp surfaces with grommets or sleeves of rubber or plastic.

X3.6 *Threaded Connections*—Do not cut threads on pipe. Molded threads on adapter fittings for transition to threaded construction are necessary except in the case of cleanout plugs. The joint between the pipe and transition fittings should be of the solvent cement type. Only approved thread tape or thread lubricant specifically intended for use with ABS plastic pipe should be used. Conventional pipe thread compound, putty, linseed oil base products, and unknown mixtures should be avoided.

X3.7 *Thread Tightness*—Where a threaded joint is made, obtain tightness by a maximum hand tightening plus additional tightening with a strap wrench, not to exceed one full turn.

X3.8 *Connection to Nonplastic Pipe*—When connecting plastic pipe to other types of piping, use only approved types of fittings and adapters designed for the specific transition.

X3.9 *Connections to Traps*—Connect traps by means of approved threaded trap adapters.

X3.10 *Connection to Closet Flanges*—Install screw-type closet flanges in the drainage system by means of a threaded connection.

X3.11 *Transition to Bell-and-Spigot Pipe*—Make connections or transition to bell-and-spigot cast iron soil pipe and fittings, and to bell-and-spigot pipe and fittings of other materials with approved mechanical compression joints designed for this use, or caulk joints made in an approved manner.

X3.12 *Building Drains Under Floor Slabs*—Make trench bottoms smooth and of uniform grade with either undis-turbed soil or a layer of selected and compacted-backfill so that no settlement will be encountered. Bottom of pipe must rest on this material throughout the entire length.

X3.13 *Thermal Expansion*—Allow for thermal expansion and movement in all piping installations by the use of approved methods. Support but do not rigidly restrain piping at branches or changes of direction. Do not anchor pipe rigidly in walls. Holes through framing members should be adequately sized to allow for free movement. Thermal expansion for installations subject to temperature changes may be determined from Table X3.1. The linear expansion shown is independent of the diameter of the pipe. Buried piping or piping installed in the crawl space under a building is normally subject to less than the ambient temperature changes.

X3.14 *Exposed Piping*—Provide adequate support where piping is exposed to wind, snow, and ice loading. Plumbing vents exposed to sunlight should be protected by water-base synthetic latex paints. Where surface temperatures exceed 165°F (74°C), piping shall be protected by means of shielding or some type of lightweight insulation. Exposure to sunlight during normal construction periods is not harmful. It is good practice to store pipe and fittings under suitable cover prior to installation.

X3.15 *Antifreeze Protection*—When necessary to protect traps and fixtures from freezing, do not use alcohol or petroleum products. Use only approved plastic pipe antifreeze packaged for this purpose or one of the following solutions:

X3.15.1 Sixty percent, by mass, of glycerin in water.

X3.15.2 Twenty-two percent, by mass, of magnesium chloride in water. Strong solutions of common table salt (sodium chloride) may also be used.

X3.16 *Commercial and Industrial Applications*—The DWV pipe will accommodate temperature of 180°F (82°C) encountered in household applications, but the nature of some applications to run to higher temperatures; for example, commercial dishwashers, require special consideration.

X3.17 *Fire-Rated Construction*—When the piping is to be installed within or penetrating fire-rated constructions, the cognizant building code authorities should be consulted for approved methods of construction or fire barriers.

TABLE X3.1 Thermal Expansion Table of ABS Schedule 40 Drain, Waste, and Vent Pipe

Length, ft	Temperature Change, °F[A]						
	40	50	60	70	80	90	100
	Length of Change, in.[B]						
20	0.5	0.7	0.8	0.9	1.0	1.2	1.3
40	1.1	1.3	1.6	1.9	2.0	2.4	2.7
60	1.6	2.0	2.4	2.8	3.2	3.6	4.0
80	2.1	2.7	3.2	3.8	4.3	4.8	5.4
100	2.7	3.4	4.0	4.7	5.4	6.0	6.7

Length, m	Temperature Change, °C			
	20	30	40	50
	Length of Change, mm			
10	20	30	40	50
20	40	60	80	100
30	60	90	120	150

[A] *Example of Temperature Change:*

Highest temperature expected	100°F
Lowest temperature expected	50°F
Total variation	50°F

[B] For a length of run of 60 ft (20 m) the chart indicates that the installation should provide for a linear expansion of 2 in. (51 mm).

Wed Feb 02 01:53:38 2005

NOTE X3.1—Fire barriers are either mechanical devices that close off penetration openings or intumescent materials that expand with heat to form a char that make a flame and water-resistant seal.

X3.17.1 All fire barriers should bear the seal of approval and classification of the approving laboratory recognized as qualified to perform such evaluations, for example UL.

NOTE X3.2—Use fire barrier products meeting this requirement.[7]

[7] Fire barrier products that have been found satisfactory for this purpose are: "Flamarest," available from AVCO Systems Division, Lowell Industrial Park, Lowell, MA 01851; "Flameseal," available from Nelson Electric, P.O. Box 726, Tulsa, OK 74101; "Firebarrier," available from 3M Electrical Products Division, 225-4N 3M Center, St. Paul, MN 55144; and "Fire Stop Foam," available from Dow Corning, Dept. A6009, Midland, MI 48686.

X4. PREFABRICATED PLUMBING TREES

X4.1 When prefabricated plumbing trees are assembled, it is important that the recommendation of Appendix X2 on joining and Appendix X3 on installation, where applicable, be followed for satisfactory results.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Practice for Making Solvent-Cemented Joints with Poly(Vinyl Chloride) (PVC) Pipe and Fittings[1]

This standard is issued under the fixed designation D 2855; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense. Consult the DoD Index of Specifications and Standards for the specific year of issue which has been adopted by the Department of Defense.

1. Scope

1.1 This practice describes a procedure for making joints with poly(vinyl chloride) plastic (PVC) pipes, both plain ends and fittings, and bell ends, by means of solvent cements. These procedures are general ones for PVC piping. In non-pressure applications, simplified procedures may be used. Manufacturers should supply specific instructions for their particular products, if and when it seems necessary.

1.2 The techniques covered are applicable only to PVC pipe, both plain and bell-end, and fittings of the same classes as described in Specification D 1784.

1.3 Pipe and fittings are manufactured within certain tolerances to provide for the small variations in the extrusion, belling, and molding processes and are not to exact size. A partial list of standards for PVC pipe, fittings, and cements suitable for use in making solvent-cemented joints is given in Appendix X1.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.5 The text of this practice references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the practice.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise specified.

4. Summary of Practice

4.1 To consistently make good joints, the following should be clearly understood and adhered to:

4.1.1 The joining surfaces must be softened (dissolved) and made semi-fluid.

4.1.2 Sufficient cement must be applied to fill the gap between pipe and fitting.

4.1.3 Assembly of pipe and fittings must be made while the surfaces are still wet and fluid.

4.1.4 Joint strength develops as the cement dries. In the tight part of the joint the surfaces will tend to fuse together; in the loose part the cement will bond to both surfaces.

4.2 Penetration and dissolving can be achieved by the cement itself, by a suitable primer, or by the use of both primer and cement. A suitable primer will penetrate and dissolve the plastic more quickly than cement alone. In cold weather, more time and additional applications are required (see Fig. 1).

4.3 More than sufficient cement to fill the loose part of the joint must be applied (see Fig. 2). Besides filling the gap, adequate cement layers will penetrate the surfaces and also remain wet until the joint is assembled.

4.4 If the cement coatings on the pipe and fittings are wet and fluid when assembly takes place, they will tend to flow together and become *one* cement layer. Also, if the cement is wet the surfaces beneath them will still be soft, and these dissolved surfaces in the tight part of the joint will tend to fuse together (see Fig. 3).

4.5 As the solvent dissipates, the cement layer and the dissolved surfaces will harden with a corresponding increase

[1] This practice is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.20 on Joining.

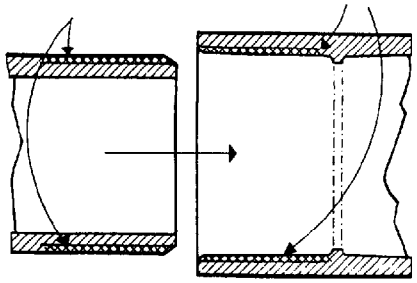

FIG. 1 Areas of Pipe and Fittings to Be Softened (Dissolved) and Penetrated

in joint strength. A good joint will take the required working pressure long before the joint is fully dry and final strength is obtained. In the tight (fused) part of the joint, strength will develop more quickly than in the looser (bonded) part of the joint. Completed joints should not be disturbed until they have cured sufficiently to withstand handling. Joint strength develops as the cement dries. Information about the development of bond strength of solvent cemented joints is available (see Fig. 4).

5. Significance and Use

5.1 The techniques described herein can be used to produce strong pressure-tight joints between PVC pipe and fittings, either in shop operations or in the field. However, skill and knowledge on the part of the operator are required to obtain a good quality joint. This skill and knowledge can be obtained by making joints under the guidance of skilled operators and testing them until good quality joints are obtained.

6. Materials

6.1 *Pipe and Fittings*—The pipe and fittings should meet the requirements of current applicable PVC piping standards. A list of these standards is given in Appendix X1.

6.2 *Solvent Cement:*

6.2.1 *Specification*—The solvent cement should meet all the requirements of Specification D 2564.

6.2.2 *Selection*—PVC solvent cements are available in a variety of viscosities and wet film thicknesses to cover the range of pipe sizes from ⅛ to 12 in. and for interference-fit joints as well as noninterference joints, as found in some Schedule 80 pipe and fittings. One of the general principles of solvent cementing that should be strictly adhered to is: sufficient cement must be applied to fill the gap between pipe and fitting.

6.2.2.1 The ability of a solvent cement to fill a gap in a

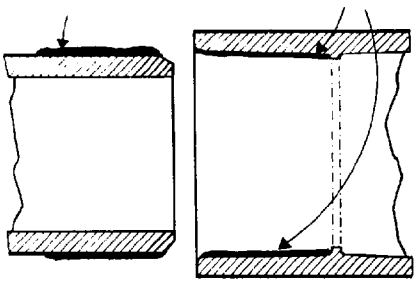

FIG. 2 Cement Coatings of Sufficient Thickness

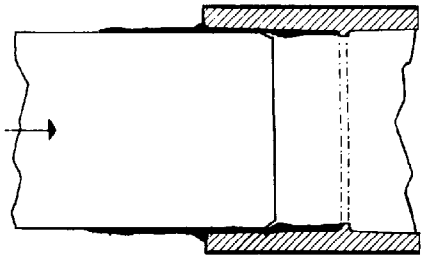

FIG. 3 Assembly of Surfaces While They Are Wet and Soft

pipe joint can be determined by considering its viscosity and wet-film thickness (see Note X3.1). A guide to the proper selection of a solvent cement for the various pipe sizes is given in Tables X3.1 and X3.2, where PVC solvent cements are classified (for purposes of identification) as regular-bodied, medium-bodied, and heavy-bodied cement based on minimum viscosity and minimum wet-film thickness.

6.2.3 *Storage*—PVC solvent cements should be stored in a cool place except when actually in use at the job site. These cements have a limited shelf life when not stored in hermetically sealed containers. Screw top containers are not considered to be hermetically sealed. Consult the cement manufacturer for specific storage recommendations on storage conditions and shelf life. The cement is unsuitable for use on the job if it exhibits an appreciable change from the original viscosity, or if a sign of gelation is apparent. Restoration of the original viscosity or removal of gelation by adding solvents or thinners is not recommended.

6.3 *Cleaners*—Cleaners are of two types, chemical and mechanical (abrasives). Cleaners are used to remove surface impurities (oil, dirt, etc.) and surface gloss.

6.3.1 *Chemical Cleaners*—The chemical cleaners are as follows:

6.3.1.1 Cleaner recommended by the pipe, fittings, or cement manufacturer, and

6.3.1.2 Methyl ethyl ketone (MEK) in accordance with Specification D 740.

6.3.2 *Mechanical Cleaners*—The mechanical cleaners are as follows:

6.3.2.1 Fine abrasive paper or cloth (180 grit or finer), and

6.3.2.2 Clean, oil-free steel wool.

6.4 *Primers*—Primers are used to clean, soften, and dissolve the joining surfaces in order to better prepare them for solvent cementing. Primers must be capable of dissolving 10 weight % of PVC resin as required in Specification F 656.

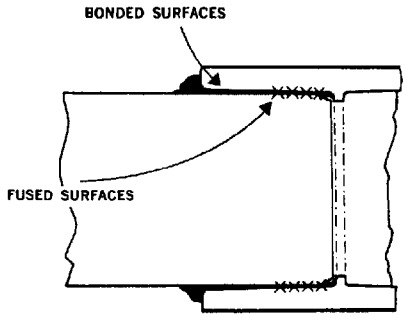

FIG. 4 Bonded and Fused Surfaces of Joined Pipe

Copyright by the ASTM International
Wed Feb 02 01:54:11 2005

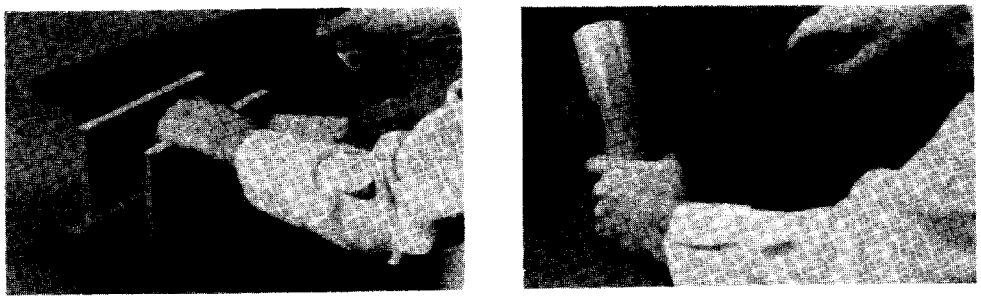

FIG. 5 Apparatus for Cutting Pipe

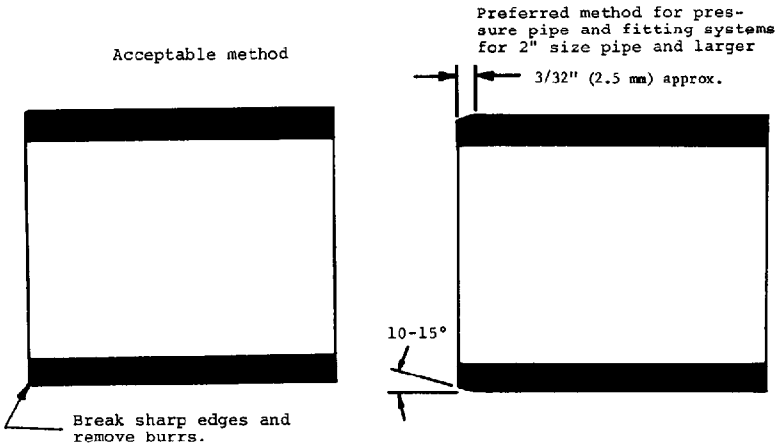

FIG. 6 Chamfer and Deburring of Pipe Edges

Primers may also be used as cleaners; refer to specific recommendations of the manufacturer.

NOTE 1—In the event of conflicting instructions from the pipe, fittings, or cement manufacturer, use a primer as well as solvent cement in the joining procedure.

6.4.1 *Primer Specification*—The primer shall meet the requirements of Specification F 656.

7. Procedure

7.1 *Cutting the Pipe*—Cut pipe square with the axis, using a fine-tooth hand saw and a miter box, or a fine-tooth power saw with a suitable guide (see Fig. 5). Wood-working blades may be used. A rotary cutter may be used if the cutting blades are specifically designed for cutting plastic pipe in such a way as not to raise a burr or ridge (flare) at the cut end of the pipe. If other tools are not available, a standard rotary metal pipe cutter may be used, provided great care is taken to remove all the ridge raised at the pipe end by the wedging action of the cutting wheels. Failure to remove the ridge will result in the cement in the fitting socket being scraped from the socket surface, producing a dry joint with a high probability of joint failure. Remove all burrs with a knife, file, or abrasive paper.

FIG. 7 Pipe Entering Dry Fitting

7.2 *Joint Preparation*—Chamfer or deburr pipe, or both, approximately as illustrated in Fig. 6. Failing to chamfer the edge of the pipe may remove the cement and softened material from the fitting socket, and result in a leaking joint.

7.3 *Test Dry Fit of the Joint* (see Fig. 7)—The solvent cement joint is designed so that there will generally be interference of pipe wall with the fitting socket before the pipe is fully inserted. Insert the pipe into the fitting and check that the interference occurs about ⅓ to ⅔ of the socket depth. Sometimes, when the pipe and fittings are at their tolerance extremes or when Schedule 80 pipe is used, it may be possible to fully insert the dry pipe into the fitting socket until it bottoms. If this occurs, the fit between the pipe and fitting should be snug. If the fit is loose or wobbly, other fittings or pipe should be selected which give a proper fit.

7.4 *Cleaning*—Surfaces to be joined must be cleaned and be free of dirt, moisture, oil, and other foreign material (see Fig. 8). If this cannot be accomplished by wiping with a clean dry cloth, a chemical or mechanical cleaner must be used. If

Copyright by the ASTM International
Wed Feb 02 01:54:11 2005

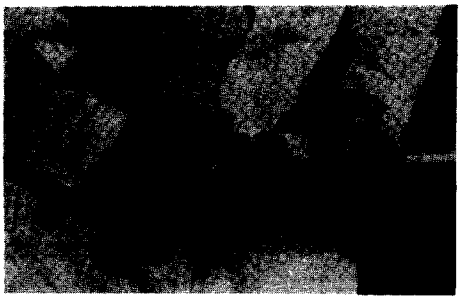

FIG. 8 Cleaning of Pipe with Dry Cloth to Remove Foreign Matter

FIG. 10 Liberal Application of Primer to Soften Surface of End of Pipe

a chemical cleaner is used, apply with an applicator. Skin contact with chemical cleaners should be avoided.

7.5 *Application Procedure:*

7.5.1 *Handling Cement*—Keep the cement can closed and in a shady place when not actually in use. *Discard* the cement when an appreciable change in viscosity takes place, or at the first sign of gelation. The cement should not be thinned. Keep the brush immersed in cement between applications.

NOTE 2—A gel condition is indicated when the cement does not flow freely from the brush or when the cement appears lumpy and stringy.

7.5.2 *Applicator Size*—Apply the cement with a natural bristle, nylon brush or suitable applicator, using a ½-in. (12-mm) brush or dauber for nominal pipe size ½-in. and less, a 1-in. (25-mm) brush or dauber for pipe up through 2-in. nominal pipe size, and a brush width at least ½ of nominal pipe size for sizes above 2 in., except that for pipe sizes 6 in. and larger a 2½-in. (60-mm) brush is adequate. Other applicators may be used provided their use results in an equivalent amount of cement being applied to the joining surfaces.

7.5.3 *Application of Primer and Cement*—PVC solvent cement is fast drying, and therefore the cement shall be applied as quickly as possible, consistent with good workmanship. It may be necessary for two workers to perform this operation for larger sizes of pipe. Under conditions of high atmospheric humidity, quick application is important to minimize condensation of moisture from the air on the cement surface. The surface temperature of the mating surfaces should not exceed 110°F (45°C) at the time of assembly. In direct sunlight or in ambient temperatures above 110°F, the pipe surface may exceed 110°F. The pipe temperature may be reduced by swabbing the surface to be cemented with clean wet rags provided the pipe is thoroughly dried before the primer and cement are applied.

7.5.3.1 First apply primer to inside socket surface (see 7.5.2 for applicator or brush size). Use a scrubbing motion to ensure penetration. Repeated applications may be necessary (see Fig. 9).

7.5.3.2 Next, soften surface of male end of pipe, to be inserted into socket, to depth of fitting socket by uniformly applying a liberal coat of primer. Be sure entire surface is well softened (dissolved) (see Fig. 10).

7.5.3.3 Again, brush inside socket surface with primer; then, without delay, apply cement to pipe while the surfaces are still wet with primer (see Fig. 11).

7.5.3.4 Apply cement lightly but uniformly to inside of socket, taking care to keep excess cement out of socket. This is to prevent solvent damage to pipe (see Fig. 12). Time is important at this stage. Apply a second coat of cement to the pipe end (see Fig. 11).

7.5.4 *Low-Temperature Application*—At temperatures below freezing, 32°F (0°C), solvents penetrate and soften the PVC surfaces more slowly than in warmer weather. For this reason it is recommended that testing be done on a piece of scrap pipe of the same lot to determine if satisfactory penetration of the surfaces can be achieved at the existing temperature. This test can be done by applying the primer, waiting a few minutes and scraping the surface with a knife edge. If sufficient penetration is achieved, some of the plastic surface of the pipe should be soft enough to be removed. If sufficient penetration is not achieved, even with multiple applications of primer, it is unlikely that a suitable joint will result.

7.5.4.1 Individual scrape tests may be needed for pipes and fittings from different manufacturers or even for pipes

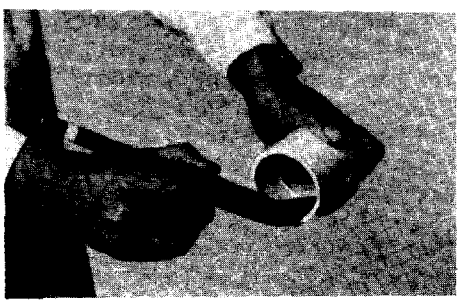

FIG. 9 Application of Primer to Inside Socket Surface

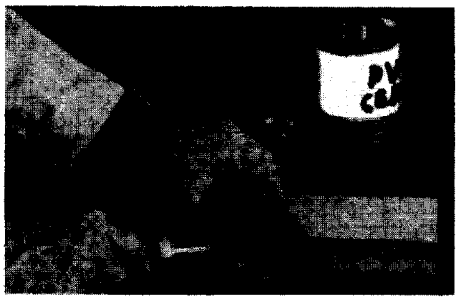

FIG. 11 Uniform Application of Cement to Outside of Pipe

Wed Feb 02 01:54:11 2005

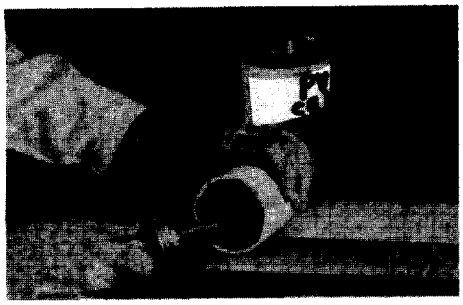

FIG. 12 Uniform But Light Application of Cement to Inside of Socket

FIG. 14 Wiping Excess Cement from Pipe After Assembly

and fittings of different lots from the same manufacturer, because of possible surface variations. Furthermore, it is good practice to use this test, regardless of ambient temperature, not only because of possible surface variations in pipes and fittings, but also because of differences in pipe primer formulations. If satisfactory penetration of joining surfaces does not occur when tested as outlined above with available cement or primers, contact your pipe, fitting, cement, or primer manufacturer before proceeding.

7.5.4.2 Important considerations for cementing in cold weather are:

(*1*) Prefabricate as much of the system as possible in a heated work area.

(*2*) Store sealed cements and primers between 40°F (5°C) to 70°F (21°C) when not in use and make sure they remain fluid. Do not use open flame or electric heaters to warm cements or primers.

(*3*) Take special care to remove moisture, including ice and snow, from pipe and fitting surfaces before applying primer or cement.

(*4*) Always use primer to soften the joining surfaces before applying cement. More than one application may be necessary.

(*5*) Allow a longer cure time before the system is used. This is necessary because the solvents evaporate more slowly at cold temperatures. Refer to Table X2.1.

7.6 *Special Instructions for Bell-End Pipe*—The procedure in 7.5 may be followed in the case of bell-end pipe except that great care should be taken not to apply an excess of cement in the bell socket, nor should any cement be applied on the bell-to-pipe transition area. This precaution is particularly important for installation of bell-end pipe with a wall thickness of less than ⅛ in. (3 mm).

7.7 *Assembly of Joint—Immediately* after applying the last coat of cement to the pipe, and while both the inside socket surface and the outside surface of the male end of the pipe are SOFT and WET with solvent cement, forcefully bottom the male end of the pipe in the socket (see Fig. 13). Turn the pipe or fitting ¼ turn during assembly (but not after the pipe is bottomed) to distribute the cement evenly.

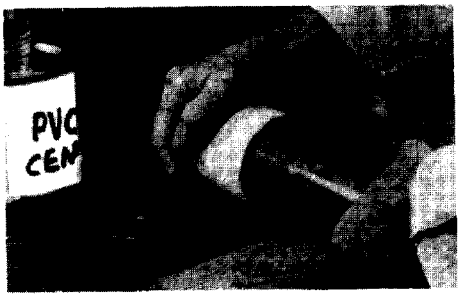

FIG. 13 Assembly of Joint

7.7.1 Assembly should be completed within 20 s after the last application of cement. The pipe should be inserted with a steady even motion. Hammer blows should not be used. If there is any sign of drying of the cement surfaces, due to delay in assembly, the surfaces should be recoated, taking care again not to apply a surplus of cement to the inside of the socket, particularly in bell-end pipe. As large axial forces are necessary for the assembly of interference fit joints in large-size pipe, two or more workers are needed for such joints. Mechanical forcing equipment, "come-alongs," or levers and braces may also be necessary. Until the cement is set in the joint, the pipe may back out of the fitting socket if not held in place for approximately 1 min after assembly. Care should be taken during assembly not to disturb or apply any force to joints previously made. Fresh joints can be destroyed by early rough handling (see 7.5.1).

7.7.2 After assembly, wipe excess cement (Fig. 14) from the pipe at the end of the fitting socket. A properly made joint will normally show a bead around its entire perimeter. Any gaps at this point may indicate a defective assembly job, due to insufficient cement or the use of light-bodied cements on large diameters where standard (heavy-bodied) cement should have been used.

7.8 *Set Time*—Handle the newly assembled joints carefully until the cement has gone through the set period. Recommended set time is related to temperature as follows:

30 min minimum at 60 to 100°F (15 to 40°C)
1 h minimum at 40 to 60°F (5 to 15°C)
2 h minimum at 20 to 40°F (−5 to 5°C)
4 h minimum at 0 to 20°F (−20 to −5°C)

8. Installation

8.1 After the set period, the pipe can be carefully placed in a prepared ditch and snaked from side to side. Prior to backfilling, the pipe shall be brought to approximate operating temperature either by shade backfilling, or by filling with water, or by allowing to stand overnight. The pipe system should be allowed to stand vented to the atmosphere prior to pressure testing. The set period before the system is pressure-tested will depend on the specific cement, the size of the pipe, the ambient temperature, and the dry-joint tightness. Necessary cure time can vary from minutes to days

Copyright by the ASTM International
Wed Feb 02 01:54:12 2005

depending on conditions and the solvent cement used. Appendix X2 shows cure schedules for several ranges of pipe sizes and temperatures. As a general rule, relatively short cure periods are satisfactory for high-ambient temperatures with low humidity, small pipe sizes, quick-drying cements, and tight-fitting joints. Longer cure periods are required for low temperatures, large pipe sizes, slow-drying cements, loose joints, and relatively high humidity. Shade backfill, leaving all joints exposed so that they can be examined during pressure tests. On long runs pressure tests should be performed on sections no longer than 5000 ft (1500 m). Test pressure should be 150 % of system design pressure and held at this pressure until the system is checked for leaks, or follow the requirements of the applicable code, whichever is higher.

9. Safe Handling of Solvent Cement

9.1 Solvent cements, primers, and cleaners for plastic pipe are made from flammable liquids and should be kept away from all sources of ignition. Good ventilation should be maintained to reduce fire hazard and to minimize breathing of solvent vapors. Avoid contact with skin and eyes.

9.2 Refer to Practice F 402 for additional information.

APPENDIXES

(Nonmandatory Information)

X1. STANDARDS FOR PVC PIPING COMPONENTS

X1.1 Standards for PVC pipe, fittings, and cements suitable for use in making solvent-cemented joints:

X1.1.1 *ASTM Standards:*

* D 1785 Specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe, Schedules 40, 80, and 120[5]

* D 2241 Specification for Poly(Vinyl Chloride) (PVC) Pressure-Rated Pipe (SDR Series)[5]

* D 2466 Specification for Poly(Vinyl Chloride) (PVC) Plastic Pipe Fittings, Schedule 40[5]

* D 2467 Specification for Socket-Type Poly(Vinyl Chloride) (PVC) Plastic Pipe Fittings, Schedule 80[5]

* D 2513 Specification for Thermoplastic Gas Pressure Pipe, Tubing, and Fittings[5]

* D 2564 Specification for Solvent Cements for Poly(Vinyl Chloride) (PVC) Plastic Pipe and Fittings[5]

* D 2665 Specification for Poly(Vinyl Chloride) (PVC) Plastic Drain, Waste, and Vent Pipe and Fittings[5]

* D 2672 Specification for Joints for IPS PVC Pipe Using Solvent Cement[5]

* D 2729 Specification for Poly(Vinyl Chloride) (PVC) Sewer Pipe and Fittings[5]

* D 2949 Specification for 3.25-in. Outside Diameter Poly(Vinyl Chloride) (PVC) Plastic Drain, Waste, and Vent Pipe and Fittings[5]

* D 3034 Specification for Type PSM Poly(Vinyl Chloride) (PVC) Sewer Pipe and Fittings[5]

* D 3138 Specification for Solvent Cements for Transition Joints Between Acrylonitrile-Butadiene-Styrene (ABS) and Poly(Vinyl Chloride) (PVC) Non-Pressure Piping Components[5]

F 409 Specification for Thermoplastic Accessible and Replaceable Plastic Tube and Tubular Fittings[5]

F 512 Specification for Smooth-Wall Poly(Vinyl Chloride) (PVC) Conduit and Fittings for Underground Installation[5]

F 656 Specification for Primers for Use in Solvent Cement Joints of Poly(Vinyl Chloride) (PVC) Plastice Pipe and Fittings[5]

F 758 Specification for Smooth-Wall Poly(Vinyl Chloride) (PVC) Plastic Underdrain Systems for Highway, Airport, and Similar Drainage[5]

F 789 Specification for Type PS-46 Poly(Vinyl Chloride) (PVC) Plastic Gravity Flow Sewer Pipe and Fittings[5]

F 891 Specification for Coextruded Poly(Vinyl Chloride) (PVC) Plastic Pipe With a Cellular Core[5]

* These standards are also ANSI standards.

X2. JOINT CURE SCHEDULE

X2.1 The cure schedules in Table X2.1 are suggested as guides. They are based on laboratory test data, and should not be taken to be the recommendations of all cement manufacturers. Individual manufacturer's recommendations for their particular cement should be followed.

TABLE X2.1 Joint Cure Schedules[A,B]

Temperature Range During Cure Period,[B] °F (°C)	Test Pressures for Pipe Sizes ½ to 1¼ in.		Test Pressures for Pipe Sizes 1½ to 3 in.		Test Pressures for Pipe Sizes 3½ to 5 in.		Test Pressures for Pipe Sizes 6 to 8 in.	
	Up to 180 psi (1240 kPa)	Above 180 to 370 psi (1240 to 2550 kPa)	Up to 180 psi (1240 kPa)	Above 180 to 315 psi (1240 to 2170 kPa)	Up to 180 psi (1240 kPa)	Above 180 to 315 psi (1240 to 2170 kPa)	Up to 180 psi (1240 kPa)	Above 180 to 315 psi (1240 to 2170 kPa)
60 to 100 (15 to 40)	1 h	6 h	2 h	12 h	6 h	18 h	8 h	24 h
40 to 60 (5 to 15)	2 h	12 h	4 h	24 h	12 h	36 h	16 h	48 h
20 to 40 (−7 to 5)	6 h	36 h	12 h	72 h	36 h[A]	4 days[A]	3 days[A]	9 days[A]
10 to 20 (−15 to −7)	8 h	48 h	16 h	96 h	72 h[A]	8 days[A]	4 days[A]	12 days[A]
Colder than 10 (−15)	**Extreme care should be exercised on all joints made where pipe, fittings, or cement is below 10°F (−12°C).**							

[A] It is important to note that at temperatures colder than 20°F (−6.7°C) on sizes that exceed 3 in., test results indicate that many variables exist in the actual cure rate of the joint. The data expressed in these categories represent only estimated averages. In some cases, cure will be achieved in less time, but isolated test results indicate that even longer periods of cure may be required.

[B] These cure schedules are based on laboratory test data obtained on Net Fit Joints (NET FIT = in a dry fit the pipe bottoms snugly in the fitting socket without meeting interference). The relative humidity in these tests was 50 % or less. Higher relative humidity may require longer cure periods.

X3. GUIDELINES FOR PVC SOLVENT CEMENT SELECTION

X3.1 Cement classifications and guidelines shown are an aid to selection, and should not be taken to be the recommendations of all cement manufacturers. Individual manufacturer's cement recommendations for pipe sizes, SDR's, and schedules should be followed, for there are situations where joint fits vary for different applications of the same nominal pipe size. In such cases variations from the guidelines given in Tables X3.1 and X3.2 may be satisfactory and desirable.

NOTE X3.1—The wet-film thickness of a solvent cement can be measured by using a Nordson Wet Film Thickness Gage or equivalent, available from Nordson Corp., Amherst, Ohio 44001, as Nordson No. 79-0015. To use this gage, dip a short length of 1-in. pipe vertically into the cement at a temperature of approximately 73°F (23°C) to a depth of 1.5 to 2 in. (40 to 50 mm) for a period of 15 s. Remove the pipe from the cement and hold the pipe horizontally for 45 s. Measure the wet-film thickness on the top surface of the pipe with the end of the gage about ¼ in. (10 mm) from the end of the pipe. With a little care and experience, the wet cement layer can be readily measured to ±0.002 in. (±0.05 mm).

NOTE X3.2—Solvent cement manufacturer's recommendations should be followed for set times and cure times when joining pipe sizes above 8 in.

NOTE X3.3—Medium-bodied and heavy-bodied cements can generally be used for smaller pipe sizes than those shown in Tables X2.1 and X3.1.

NOTE X3.4—Solvent cement manufacturer's recommendations should be followed in selecting the proper cement for joining Schedule 80 pipe sizes above 6 in.

TABLE X3.1 PVC Cements for Schedule 40 and Interference Fit (Notes X3.2 and X3.3)

Pipe Size Range, in.	Cement Type	Minimum Viscosity		Minimum Wet Film Thickness	
		cP	(mPa·s)	in.	(mm)
⅛ to 2	regular-bodied	90	(90)	0.006	(0.15)
2½ to 6	medium-bodied	500	(500)	0.012	(0.30)
8 to 12	heavy-bodied	1600	(1600)	0.024	(0.60)

TABLE X3.2 Cements for Schedule 80 (Notes X3.3 and X3.4)

Pipe Size Range, in.	Cement Type	Minimum Viscosity		Minimum Wet Film Thickness	
		cP	mPa·s	in.	(mm)
⅛ to 3	medium-bodied	500	(500)	0.012	(0.30)
3½ to 12	heavy-bodied	1600	(1600)	0.024	(0.60)

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: D 2996 – 01

An American National Standard

Standard Specification for Filament-Wound "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe[1]

This standard is issued under the fixed designation D 2996; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope *

1.1 This specification[2] covers machine-made reinforced thermosetting resin pressure pipe (RTRP) manufactured by the filament winding process up to 24 in. nominal size. Included are a classification system and requirements for materials, mechanical properties, dimensions, performance, methods of test, and marking.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are provided for information purposes only.

1.3 The following safety hazards caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—The term "fiberglass pipe" as described in Section 3 of this specification applies to both reinforced thermosetting resin pipe (RTRP) and reinforced polymer mortar pipe (RPMP). This specification covers only reinforced thermosetting resin pipe (RTRP).

NOTE 2—This specification is applicable to RTRP where the ratio of outside diameter to wall thickness is 10:1 or more.

NOTE 3—There is no similar or equivalent ISO Standard.

NOTE 4—For the purposes of this standard, polymer does not include natural polymers.

2. Referenced Documents

D 3567 Practice for Determining Dimensions of "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe and Fittings[3]

F 412 Terminology Relating to Plastic Piping Systems[4]

3. Terminology

3.1 *Definitions:*

3.1.1 *General*—Definitions are in accordance with Terminologies D 883 and F 412 and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for reinforced thermosetting resin pipe is RTRP.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *coating*—a resin layer, with or without filler or reinforcement, or both, applied to the exterior surface of the pipe structural wall.

3.2.2 *fiberglass pipe*—a tubular product containing glass-fiber reinforcements embedded in or surrounded by cured thermosetting resin; the composite structure may contain aggregate, granular or platelet fillers, thixotropic agents, pigments, or dyes; thermoplastic or thermosetting liners or coatings may be included.

3.2.3 *filament winding*—a process used to manufacture tubular goods by winding continuous fibrous glass strand roving, or roving tape, saturated with liquid resin or preimpregnated with partially cured resin (subsequent heating may be required to polymerize the resin system) onto the outside of a mandrel in a predetermined pattern under controlled tension;

[1] This specification is under the jurisdiction of ASTM Committee D20 on Plastics and is the direct responsibility of Subcommittee D20.23 on Reinforced Plastic Piping Systems and Chemical Equipment.

Current edition approved June 10, 2001. Published August 2001. Originally published as D 2996 – 71. Last previous edition D 2996 – 00.

[2] This specification was revised to include an ISO equivalency statement and a section on keywords.

[3] *Annual Book of ASTM Standards*, Vol 08.01.

[4] *Annual Book of ASTM Standards*, Vol 08.04.

***A Summary of Changes section appears at the end of this standard.**

Copyright by the ASTM International
Wed Feb 02 01:54:37 2005

the inside diameter (ID) of the pipe is fixed by the mandrel outside diameter and the outside diameter (OD) of the pipe is determined by the amount of material that is wound on the mandrel.

3.2.4 *liner*—the inner portion of the wall at least 0.005 in. (0.13 mm) in thickness, as determined in 8.3.2, which does not contribute to the strength in the determination of the hydrostatic design basis.

3.2.5 *reinforced polymer mortar pipe (RPMP)*—a fiberglass pipe with aggregate.

3.2.6 *reinforced thermosetting resin pipe (RTRP)*—a fiberglass pipe without aggregate.

3.2.7 *reinforced wall thickness*—the total wall thickness minus the liner or exterior coating thickness, or both.

4. Classification

4.1 *General*—Pipe meeting this specification is classified by type, grade, class, and hydrostatic design basis in accordance with Classification D 2310 and by a secondary cell classification system that defines the basic mechanical properties of the pipe. These types, grades, classes, hydrostatic design basis categories, and cell classification designations are as follows:

4.1.1 *Types:—Type 1*

Filament wound.

4.1.2 *Grades:—Grade 1*

Glass fiber reinforced epoxy resin pipe.

Grade 2—Glass fiber reinforced polyester resin pipe.

Grade 7—Glass fiber reinforced furan resin pipe.

4.1.3 *Classes:—Class A*

No liner.

Class B—Polyester resin liner (nonreinforced).

Class C—Epoxy resin liner (nonreinforced).

Class E—Polyester resin liner (reinforced).

Class F—Epoxy resin liner (reinforced).

Class H—Thermoplastic resin liner (specify).

Class I—Furan resin liner (reinforced).

4.1.4 *Hydrostatic Design Basis*—Two methods of classifying the hydrostatic design basis of the pipe are provided. Pipe meeting this specification may be classified using either the cyclic test method or the static test method, or both, and the designations as shown in Table 1. Appendix X1 explains how these design basis categories are to be used.

4.1.4.1 For pipe subjected to axial or end loads, the effect of these loads shall be represented in the HDB testing. In the designation code, the numeral 1 shall immediately follow the HDB letter class if free-end type closures were used and the numeral 2 shall immediately follow the HDB letter class if restrained-end type closures were used to establish the HDB.

TABLE 1 Hydrostatic Design Basis Categories

Cyclic Test Method		Static Test Method	
Designation	Hoop Stress, psi (MPa)	Designation	Hoop Stress, psi (MPa)
A	2 500 (17.2)	Q	5 000 (34.5)
B	3 150 (21.7)	R	6 300 (43.4)
C	4 000 (27.6)	S	8 000 (55.2)
D	5 000 (34.5)	T	10 000 (68.9)
E	6 300 (43.4)	U	12 500 (86.2)
F	8 000 (55.2)	W	16 000 (110)
G	10 000 (68.9)	X	20 000 (138)
H	12 500 (86.2)	Y	25 000 (172)
		Z	31 500 (217)

4.1.5 *Mechanical Properties*—Table 2 presents a cell classification system for identifying the mechanical properties of pipe covered by this specification.

NOTE 5—All possible combinations covered by the above classification system may not be commercially available.

4.1.6 *Designation Code*—The pipe designation code shall consist of the abbreviation RTRP, followed by the type and grade in Arabic numerals, the class and static or cyclic HDB level in capital letters, the type of end closure used, and four Arabic numbers identifying, respectively, the cell classification designations of the short-term rupture strength, longitudinal tensile strength, longitudinal tensile modulus, and apparent stiffness of the pipe.

Example: RTRP-11FA1-1334. Such a designation would describe a filament-wound, glass-fiber reinforced, epoxy pipe having a reinforced epoxy liner; a cyclic pressure strength exceeding 2500 psi (17.2 MPa) using free-end closures; a short-term rupture strength exceeding 10 000 psi (68.9 MPa); a longitudinal tensile strength exceeding 25 000 psi (172 MPa); a longitudinal tensile modulus exceeding 3×10^6 psi (20.7×10^3MPa); and an apparent stiffness factor exceeding 1500 $in.^3 \cdot lbf/in.^2$ (170 $mm^3 \cdot kPa$).

5. Materials and Manufacture

5.1 *General*—The resins, reinforcements, colorants, fillers, and other materials, when combined as a composite structure, shall produce a pipe that shall meet the performance requirements of this specification.

6. Physical Requirements

6.1 *Workmanship*—The pipe shall be free of all defects including indentations, delaminations, bubbles, pinholes, foreign inclusions, and resin-starved areas which, due to their nature, degree, or extent, detrimentally affect the strength and serviceability of the pipe. The pipe shall be as uniform as commercially practicable in color, opacity, and other physical properties. The pipe shall be round and straight and the bore of the pipe shall be smooth and uniform. All pipe ends shall be cut at right angles to the axis of the pipe and any sharp edges removed.

6.2 *Dimensions and Tolerances*:

6.2.1 *Inside and Outside Diameter*—The inside and outside diameter and tolerances of pipe meeting these specifications shall conform to the requirements in one of the Tables 3-6, when determined in accordance with 8.3.1.

6.2.2 *Wall Thickness*—The minimum wall thickness of pipe furnished under this specification shall not at any point be less than 87.5 % of the nominal wall thickness published in the manufacturer's literature current at the time of purchase when measured in accordance with 8.3.1.

6.3 *Performance*—Pipe meeting this specification shall be categorized by a long-term static or cyclic hydrostatic design basis as shown in Table 1 when tested in accordance with 8.4 or 8.5. Additionally, the pipe shall meet the applicable cell limit

requirements for short-term rupture strength, longitudinal tensile strength, longitudinal tensile modulus, and apparent stiffness factor as described in Table 2 when tested in accordance with 8.6 through 8.8.

6.3.1 Any significant changes in the original pipe categorized in 6.3, with respect to materials or manufacturing process, will require recategorizing according to 6.3. These changes include, but are not limited to: a change in reinforcement type, composition, or binder; a change in resin type, composition, or cure; or change in linear composition, thickness, or cure.

NOTE 6—The purchaser should consult the manufacturer for the proper class, type, and grade of pipe to be used under the installation and operating conditions, with respect to temperature, conveyed fluid, pressure, etc., that will exist for the project in which the pipe is to be used.

7. Sampling

7.1 At least one sample of pipe, to determine conformance of the material to the short-term hoop tensile rupture requirements as shown in Table 2, shall be taken at random on a weekly basis or on each production run, whichever is the most frequent. The rate of sampling for the other tests listed shall be in accordance with accepted statistical practice or as agreed upon between the purchaser and the seller.

7.2 For individual orders, only those additional tests and

16	15.40 + 0.05 −0.08	391.16 + 1.27 −2.03

number of tests specifically agreed upon between the purchaser and the seller need to be conducted.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5 % relative humidity for not less than 48 h prior to test, in accordance with Procedure A of Methods D 618, for those tests where conditioning is required, and in all cases of disagreement.

8.2 *Test Conditions*—Conduct the tests in the Standard Laboratory Atmosphere of 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5 % relative humidity, unless otherwise specified in the test method or in this specification.

8.3 *Dimensions and Tolerances*:

8.3.1 *Wall Thickness and Diameter*—Determine in accordance with Practice D 3567.

8.3.2 *Liner Thickness*—If the test specimens contain a liner, determine the average liner thickness in accordance with Practice D 3567.

8.4 *Long-Term Cyclic Hydrostatic Strength*—Determine in accordance with Procedure A of Method D 2992, following Test Method D 2143.

8.5 *Long-Term Static Hydrostatic Strength*—Determine in accordance with Procedure B of Method D 2992, following Test Method D 1598.

8.6 *Short-Term Hydrostatic Failure Strength*—Determine in accordance with Test Method D 1599.

8.7 *Longitudinal Tensile Properties*— Determine in accordance with Test Methods D 2105 or D 638.

8.8 *Stiffness Factor*—Determine in accordance with Test Method D 2412. The reported stiffness shall be based on 5 % deflection.

9. Certification

9.1 When agreed upon in writing between the purchaser and the seller, a certification shall be made on the basis of acceptance of material. This shall consist of a copy of the manufacturer's test report or a statement by the seller (accompanied by a copy of the test results) that the material has been sampled, tested, and inspected in accordance with the provisions of the specification. Each certification so furnished shall be signed by an authorized agent of the seller or manufacturer.

9.2 When original identity cannot be established, certification can only be based upon the sampling procedure provided by the applicable specification.

10. Product Marking

10.1 Each piece of pipe shall be marked at least once per section. Each piece of pipe shall be marked with the following information in such a manner that it remains legible under normal handling and installation practices:

10.1.1 Nominal pipe size (for example, 2 in.).

10.1.2 Identification of reinforced thermosetting resin pipe in accordance with the designation code given in Section 4.

10.1.3 ASTM D 2996 with which the pipe complies.

10.1.4 Manufacturer's name (or trademark).

11. Keywords

11.1 filament-wound FRP pipe; mechanical properties; physical properties; pressure rating; tolerances; wall thickness

APPENDIX

(Nonmandatory Information)

X1. HYDROSTATIC DESIGN BASIS, CATEGORIES, SERVICE FACTORS, AND PRESSURE RATINGS

X1.1 Hydrostatic Design Basis

X1.1.1 The hydrostatic design basis for reinforced thermosetting resin pipe is the estimated long-term hydrostatic strength obtained in accordance with Method D 2992. In Method D 2992 either Procedure A, using data obtained in accordance with Test Method D 2143, or Procedure B, using data obtained in accordance with Test Method D 1598, is used to determine the estimated long-term hydrostatic strength. This strength in the wall of the pipe is equal to the circumferential stress due to internal hydrostatic pressure that will fail the pipe when extrapolated to 150×10^6 pressure cycles (Procedure A) or to 100 000 h under continuously applied pressure (Procedure B).

X1.2 Hydrostatic Design Basis Categories

X1.2.1 The hydrostatic design basis category is obtained from Table X1.1 or Table X1.2 using the estimated long-term

TABLE X1.1 Hydrostatic Design Basis Categories by Procedure A

Hydrostatic Design Basis Category, psi (MPa)	Range of Calculated Values, psi (MPa)
2 500 (17.2)	2 400 to 3 010 (16.5 to 20.8)
3 150 (21.7)	3 020 to 3 020 (20.8 to 26.3)
4 000 (27.6)	3 830 to 4 790 (26.4 to 33.0)
5 000 (34.5)	4 800 to 5 900 (33.1 to 40.7)
6 300 (43.4)	6 000 to 7 500 (41.4 to 51.7)
8 000 (55.2)	7 600 to 9 500 (52.4 to 65.5)
10 000 (68.9)	9 600 to 11 900 (66.2 to 82.0)
12 500 (86.2)	12 000 to 15 200 (82.7 to 105)

TABLE X1.2 Hydrostatic Design Basis Categories by Procedure B

Hydrostatic Design Basis Category, psi (MPa)	Range of Calculated Values, psi (MPa)
5 000 (34.5)	4 800 to 5 900 (33.1 to 40.7)
6 300 (43.4)	6 000 to 7 500 (41.4 to 51.7)
8 000 (55.2)	7 600 to 9 500 (52.4 to 65.5)
10 000 (68.9)	9 600 to 11 900 (66.2 to 82.1)
12 500 (86.2)	12 000 to 15 200 (82.9 to 105)
16 000 (112)	15 300 to 18 900 (105 to 130)
20 000 (138)	19 000 to 23 000 (131 to 159)
25 000 (173)	24 000 to 29 000 (165 to 200)
31 500 (217)	30 000 to 38 000 (207 to 262)

hydrostatic strength as the calculated value.

X1.3 Service (Design) Factor

X1.3.1 The service (design) factor is a number equal to 1.00 or less which takes into consideration all the variables and degree of safety involved in a reinforced thermosetting resin pressure piping installation and is selected for the application on the basis of two general groups of conditions. The first group considers the manufacturing and testing variables (specifically, normal variations in the material, manufacture, dimensions, good handling techniques, and in the evaluation procedures of this method). The second group considers the application or use (specifically, installation, environment, temperature hazard involved, life expectancy desired, and the degree of reliability selected).

NOTE X1.1—It is not the intent of this standard to give service (design) factors. The service (design) factor should be selected by the design engineer after fully evaluating the service conditions and the engineering properties of the specific pipe material under consideration. Recommended service (design) factors will not be developed or issued by ASTM.

X1.4 Hydrostatic Design Stress

X1.4.1 The hydrostatic design stress is the estimated maximum tensile stress in the wall of the pipe in the circumferential orientation due to internal hydrostatic pressure that can be applied continuously with a high degree of certainty that failure will not occur. It is obtained by multiplying the hydrostatic design basis as determined by Procedure A or Procedure B by the service (design) factor.

X1.5 Pressure Rating

X1.5.1 The pressure rating is the estimated maximum pressure that the medium in the pipe can exert continuously with a high degree of certainty that failure of the pipe will not occur.

X1.5.2 The pressure rating for each diameter and wall thickness of pipe and fitting is calculated from hydrostatic design stress for the specific pipe by means of the following formula:

$$S = P\,(D - t)/2t$$

where:

S = hydrostatic design stress, psi (MPa),
P = pressure rating, psi (MPa),
D = average outside diameter, in. (mm), and
t = minimum reinforced wall thickness, in. (mm).

SUMMARY OF CHANGES

Committee D20 has identified the location of selected changes to this standard since the last issue D 2996 – 00 that may impact the use of this standard.

(*1*) Changed acronym, RPMP, from reinforced *plastic* mortar pipe to reinforced *polymer* mortar pipe.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: D 2997 – 01

An American National Standard

Standard Specification for Centrifugally Cast "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe[1]

This standard is issued under the fixed designation D 2997; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This specification covers machine-made glass-fiber-reinforced thermosetting-resin pressure pipe manufactured by the centrifugal casting process. Included are a classification system and requirements for materials, mechanical properties, dimensions, performance, test methods, and marking.

NOTE 1—The term "fiberglass pipe" as described in Section 3 applies to both reinforced thermosetting resin pipe (RTRP) and reinforced polymer mortar pipe (RPMP).

NOTE 2—Pipe covered by this specification has been found suitable for conveying gases, petroleum products, or corrosive fluids.

NOTE 3—For the purposes of this standard, polymer does not include natural polymers.

1.2 The values given in parentheses are for information only.

NOTE 4—There is no similar or equivalent ISO standard.

1.3 The following precautionary caveat pertains only to the test method portion, Section 7, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminologies D 883 and F 412 and abbreviations with Terminology D 1600, unless otherwise indicated.

3.2 *Definitions of Terms Specific to This Standard:* Descriptions of Terms Specific to This Standard:

3.2.1 *aggregate, n*—a siliceous sand conforming to the requirements of Specification C 33, except that the requirements for gradation shall not apply.

3.2.2 *centrifugal casting, n*—a manufacturing process used to produce tubular goods by applying resin and reinforcement to the inside of a mold that is rotated and heated, subsequently polymerizing the resin system. The outside diameter (OD) of the finished pipe is fixed by the inside diameter (ID) of the mold tube. The inside diameter of the pipe is determined by the amount of material introduced into the mold.

3.2.3 *fiberglass pipe, n*—a tubular product containing glass-fiber reinforcements embedded in or surrounded by cured thermosetting resin; the composite structure may contain aggregate, granular or platelet fillers, thixotropic agents, pigments, or dyes; thermoplastic or thermosetting liners or coatings may be included.

3.2.4 *liner, n*—the inner portion of the wall at least 0.005 in. (0.13 mm) in thickness, as determined in 7.4 which does not

contribute to the strength in the determination of the hydrostatic design basis.

3.2.5 *reinforced polymer mortar pipe (RPMP), n*—a fiberglass pipe with aggregate.

3.2.6 *reinforced thermosetting resin pipe (RTRP), n*—a fiberglass pipe without aggregate.

3.2.7 *reinforced wall thickness, n*—the total wall thickness minus the liner or exterior surface resin layer thickness, or both.

4. Classification

4.1 *General*—Pipe meeting this specification is classified by type, grade, class, and hydrostatic design basis in accordance with Classification D 2310, and by a secondary cell classification system that defines the basic mechanical properties of the pipe. These types, grades, classes, hydrostatic design basis categories, and cell classification designations are as follows:

4.1.1 *Types: —Type II*

Centrifugally cast pipe.

4.1.2 *Grades: —Grade 1*

Glass-fiber-reinforced epoxy-resin pipe.

Grade 2—Glass-fiber-reinforced polyester-resin pipe.

Grade 3—Glass-fiber reinforced polydicyclopentadiene-resin pipe.

Grade 8—Glass-fiber-reinforced polyester-resin mortar pipe.

Grade 9—Glass fiber reinforced epoxy resin mortar pipe.

4.1.3 *Classes:—Class A*

No liner.

Class B—Polyester-resin liner, nonreinforced.

Class C—Epoxy-resin liner, nonreinforced.

Class D—Polydicyclopentadiene-resin liner, nonreinforced.

4.1.4 *Hydrostatic Design Basis*—Two methods of classifying the hydrostatic design basis of the pipe are provided. Pipe meeting this specification may be classified using either the cyclic test method or the static test method, or both, and the designations are shown in Table 1. Appendix X1 explains how to use the design basis categories shown in Table 1.

4.1.5 *Mechanical Properties*—Table 2 presents a cell classification system for identifying the mechanical properties of pipe covered by this specification.

NOTE 5—All possible combinations covered by the preceding classification system may not be commercially available.

4.1.6 *Designation Code*—The pipe designation code shall consist of the abbreviation RTRP or RPMP, followed by the type and grade in Arabic numerals, the class and static or cyclic hydrostatic design basis level in capital letters, and four Arabic numbers identifying, respectively, the cell classification designations of the short-term rupture strength, longitudinal tensile strength, tensile modulus, and pipe stiffness. Thus, a complete pipe designation code shall consist of four letters, two numerals, two letters, and four numerals.

4.1.6.1 *Example*—RTRP-21CA-1334. Such a designation would describe a centrifugally cast, glass-fiber-reinforced, epoxy pipe having a nonreinforced epoxy liner; a long-term cyclic pressure strength level exceeding 2500 psi (17.2 MPa); a short-term rupture strength exceeding 4000 psi (27.6 MPa); a longitudinal tensile strength exceeding 16 000 psi (110 MPa); a longitudinal tensile modulus exceeding 1.5 by 10^6 psi (10 300 MPa); and a pipe stiffness of 72 psi (496 kPa).

NOTE 6—Although the *Form and Style for ASTM Standards* manual requires that the type classification be roman numerals, it is recognized that few companies have stencil-cutting equipment for this style of type, and it is therefore acceptable to mark the product type in arabic numbers.

TABLE 1 Hydrostatic Design Basis Categories

Cyclic Test Method		Static Test Method	
Designation	Hoop Stress, psi (MPa)	Designation	Hoop Stress, psi (MPa)
A	2 500 (17.2)	Q	5 000 (34.5)
B	3 150 (21.7)	R	6 300 (43.4)
C	4 000 (27.6)	S	8 000 (55.2)
D	5 000 (34.5)	T	10 000 (68.9)
E	6 300 (43.4)	U	12 500 (86.2)
F	8 000 (55.2)	W	16 000 (110)
G	10 000 (68.9)	X	20 000 (138)
H	12 500 (86.2)	Y	25 000 (172)
		X	31 500 (217)

5. Materials

5.1 *General*—The resins, reinforcements, colorants, fillers, and other materials, when combined as a composite structure, shall produce a pipe that shall be classified in accordance to this specification based on performance.

6. Requirements

6.1 *Workmanship*—The pipe shall be free from all defects, including indentations, delaminations, bubbles, pinholes, foreign inclusions, and resin-starved areas which, as a result of their nature, degree, or extent, detrimentally affect the strength and serviceability of the pipe. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties. The pipe shall be round and straight, and the bore of the pipe shall be smooth and uniform. All pipe ends shall be cut at right angles to the axis of the pipe, and any sharp edges removed.

6.2 *Dimensions and Tolerances*:

6.2.1 *Outside Diameter*—The outside diameter and tolerances of pipe meeting this specification shall conform to the requirements in Table 3, when determined in accordance with 7.4.

6.2.2 *Wall Thickness*—The minimum wall thickness of pipe furnished under this specification shall not at any point be less than 87.5 % of the nominal wall thickness published in the manufacturer's literature, current at the time of purchase, when measured in accordance with 7.4.

6.2.3 *Liner Thickness*—Except for Class A unlined products, all other classes shall have a minimum liner thickness of 0.005 in. (5 mil), when measured in accordance with 7.4.

6.3 *Performance*—Pipe meeting this specification shall be categorized by a long-term static or cyclic hydrostatic design basis shown in Table 1, when tested in accordance with 7.5 and 7.6. Additionally, the pipe shall meet the applicable cell limit requirements for short-term rupture strength, longitudinal tensile strength, tensile modulus, and pipe stiffness described in Table 2, when tested in accordance with 7.7, 7.8, and 7.9.

7. Test Methods

7.1 *Conditioning*—Condition the test specimens at 23 ±

TABLE 3 Outside Dimensions and Tolerances

Nominal Pipe Size, in.	in.	(mm)
1	1.315 ± 0.009	(33.401 ± 0.229)
1½	1.900 ± 0.009	(48.260 ± 0.229)
2	2.375 ± 0.012	(60.325 ± 0.305)
2½	2.875 ± 0.012	(73.025 ± 0.305)
3	3.500 ± 0.012	(88.900 ± 0.305)
4	4.500 ± 0.015	(114.300 ± 0.381)
6	6.625 ± 0.025	(168.275 ± 0.635)
8	8.625 ± 0.025	(219.075 ± 0.635)
10	10.750 ± 0.025	(273.050 ± 0.635)
12	12.750 ± 0.025	(323.850 ± 0.635)
14	14.000 ± 0.035	(355.600 ± 0.889)

2°C (73.4 ± 3.6°F) and 50 ± 5 % relative humidity for not less than 48 h prior to test, in accordance with Procedure A of Practice D 618, for those tests where conditioning is required, and in all cases of disagreement.

7.2 *Test Conditions*—Conduct the tests in the Standard Laboratory Atmosphere of 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5 % relative humidity, unless otherwise specified in the test specification.

7.3 *Sampling*—Samples of pipe to determine conformance of the material to be short-term rupture requirements shown in Table 2 shall be taken at random on a weekly basis or on each production run, whichever is the most frequent. The rate of sampling for the other tests listed shall be in accordance with the accepted statistical practice and as agreed upon between the purchaser and the seller.

NOTE 7—For individual orders, only those additional tests and number of tests specifically agreed upon between the purchaser and the seller need be conducted.

7.4 *Dimensions and Tolerances*—Determine in accordance with Practice D 3567.

7.5 *Long-Term Cyclic Pressure Strength*—Determine in accordance with Procedure A of Practice D 2992.

7.6 *Long-Term Static Pressure Strength*—Determine in accordance with Procedure B of Practice D 2992.

7.7 *Short-Term Rupture Strength*—Determine in accordance with Test Method D 1599.

7.8 *Longitudinal Tensile Properties*—Determine in accordance with Test Method D 2105.

7.9 *Pipe Stiffness*—Determine in accordance with Test Method D 2412. The reported stiffness shall be based on 5 % deflection.

8. Certification

8.1 When agreed upon in writing by the purchaser and the seller, a certification shall be made the basis of acceptance of the material. This shall consist of a copy of the manufacturer's test report or a statement by the seller accompanied by a copy of the test results, that the material has been sampled, tested, and inspected in accordance with the provisions of the specification. Each certification so furnished shall be signed by an authorized agent of the seller or the manufacturer.

8.2 When original identity cannot be established, certification can only be based on the sampling procedure provided by the applicable specification.

9. Marking

9.1 Each piece shall be marked at least once and at lengths of at least every 15 ft. Each piece of pipe shall be marked with the following information in such a manner that it remains legible under normal handling and installation practices:

9.1.1 Nominal pipe size (for example, 2 in.),

9.1.2 Identification of fiberglass pipes in accordance with the designation code given in Section 5,

9.1.3 This designation, D 2997, with which the pipe complies, and

9.1.4 Manufacturer's name (or trademark).

APPENDIX

(Nonmandatory Information)

X1. HYDROSTATIC DESIGN BASIS, CATEGORIES, SERVICE FACTORS, AND PRESSURE RATINGS

X1.1 Hydrostatic Design Basis

X1.1.1 The hydrostatic design basis is the estimated long-term hydrostatic strength on which service factors (1.0 or less) are applied to obtain a hydrostatic design stress. The long-term hydrostatic strength is obtained by Practice D 2992. In Practice D 2992, either Procedure A using data obtained in accordance with Test Method D 2143 or Procedure B using data obtained in accordance with Test Method D 1598 is used to determine the long-term hydrostatic strength extrapolated at 50 years.

X1.1.2 The long-term hydrostatic strength is the estimated tensile stress in the wall of the pipe in the hoop orientation due to internal hydrostatic pressure that will cause failure after 50 years (657×10^6 pressure cycles by Procedure A or 438 000 h of static pressure by Procedure B).

X1.2 Hydrostatic Design Basis Categories

X1.2.1 The hydrostatic design basis is obtained by categorizing the long-term strength in accordance with Table X1.1 or Table X1.2.

X1.3 Service (Design) Factor

X1.3.1 The service (design) factor is a number equal to 1.00 or less that takes into consideration all the variables and degree of safety involved in a fiberglass pressure piping installation, and is selected for the application on the basis of two general groups of conditions.

X1.3.2 The first group considers the manufacturing and testing variables, specifically normal variations in the material, manufacture, dimensions, good handling techniques, and in the evaluation procedures of this method. The second group considers the application or use, specifically installation, environment, temperature, hazard involved, life expectance desired, and the degree of reliability selected.

TABLE X1.1 Hydrostatic Design Basis Categories by Procedure A

Hydrostatic Design Basis Category, psi (MPa)	Range of Calculated Values, psi (MPa)
2 500 (17.2)	2 400 to 3 010 (16.5 to 20.8)
3 150 (21.7)	3 020 to 3 820 (20.8 to 26.3)
4 000 (27.6)	3 830 to 4 790 (26.4 to 33.0)
5 000 (34.5)	4 800 to 5 900 (33.1 to 40.7)
6 300 (43.4)	6 000 to 7 500 (41.4 to 51.7)
8 000 (55.2)	7 600 to 9 500 (52.4 to 65.5)
10 000 (68.9)	9 600 to 11 900 (66.2 to 82.0)
12 500 (86.2)	12 000 to 15 200 (82.7 to 105)

TABLE X1.2 Hydrostatic Design Basis Categories by Procedure B

Hydrostatic Design Basis Category, psi (MPa)	Range of Calculated Values, psi (MPa)
5 000 (34.5)	4 800 to 5 900 (33.1 to 40.7)
6 300 (43.4)	6 000 to 7 500 (41.4 to 51.7)
8 000 (55.2)	7 600 to 9 500 (52.4 to 65.5)
10 000 (68.9)	9 600 to 11 900 (66.2 to 82.0)
12 500 (86.2)	12 000 to 15 200 (82.7 to 105)
16 000 (110)	15 300 to 18 900 (106 to 130)
20 000 (138)	19 000 to 23 000 (131 to 159)
25 000 (172)	24 000 to 29 000 (166 to 200)
31 500 (217)	30 000 to 38 000 (207 to 262)

NOTE X1.1—It is not the intent of this specification to give service (design) factors. The service (design) factor should be selected by the design engineer after evaluating fully the service conditions and the engineering properties of the specific pipe material under consideration. Recommended service (design) factors will not be developed or issued by ASTM.

X1.4 Hydrostatic Design Stress

X1.4.1 The hydrostatic design stress is the estimated maximum tensile stress in the wall of the pipe in the circumferential orientation as a result of internal hydrostatic pressure that can be applied continuously with a high degree of certainty that failure will not occur. It is obtained by multiplying the hydrostatic design basis as determined by Procedure A or Procedure B by the service (design) factor.

X1.5 Pressure Rating

X1.5.1 The pressure rating is the estimated maximum pressure that the medium in the pipe can exert continuously with a high degree of certainty that failure of the pipe will not occur.

X1.5.2 The pressure rating for each diameter and wall thickness of pipe and fitting is calculated from the hydrostatic design stress for the specific pipe by means of the ISO formula:

$$S = P(D - t)/2t$$

where:

S = hoop stress,
P = internal pressure,
D = average outside diameter, and
t = minimum reinforced wall thickness.

SUMMARY OF CHANGES

Committee D20 has identified the location of selected changes to this standard since the last issue, D 2997–99, that may impact this standard.

(*1*) Changed acronym, RPMP, definition from reinforced *plastic* mortar pipe to reinforced *polymer* mortar pipe.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Specification for Joints for Plastic Pressure Pipes Using Flexible Elastomeric Seals[1]

This standard is issued under the fixed designation D 3139; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers the types of joints required for plastic pipe pressure systems with a wall thickness equal to or greater than that of SDR 64 and intended for use in supply and distribution lines for water, using flexible elastomeric seals. This specification covers the test requirements, test method, and materials. The test methods described are not intended to be routine quality control tests, but are to evaluate the performance characteristics of the joint.

1.2 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.3 The following safety hazards caveat pertains to the test method portion, Section 6, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

D 2837 Test Method for Obtaining Hydrostatic Design Basis for Thermoplastic Pipe Materials[2]

F 477 Specification for Elastomeric Seals (Gaskets) for Joining Plastic Pipe[2]

2.2 *AWWA Standard:*

AWWA C 651 Standard for Disinfecting Water Mains[3]

2.3 *NSF Standard:*

ANSI/NSF Standard No. 61 for Drinking Water System Components-Health Effects[4]

3. Terminology

3.1 Definitions—This specification covers two types of mechanical joints based on effecting water tightness through compression of an elastomeric seal or ring:

3.1.1 *mechanical joint*—a joint in which a positive seal is achieved when a gasket is compressed by means of a mechanical device.

3.1.2 *push-on-joint*—a joint in which a continuous elastomeric ring gasket is compressed into an annular space formed by the pipe or fitting socket and the spigot end of the pipe, and forms a positive seal after being assembled. Details of the joint design and assembly shall be in accordance with the manufacturer's instructions.

4. Materials and Manufacture

4.1 The materials used in elastomeric seals shall meet the requirements of Specification F 477.

4.2 *Lubricant*—The lubricant shall be nontoxic and shall have no deteriorating effects on the gasket and pipe materials. It shall not impart taste or odor to water in a pipe that has been flushed in accordance with AWWA C 651. When used in a potable water system, the lubricant shall meet the requirements of ANSI/NSF Standard No. 61. The lubricant container shall be labeled with the manufacturer's trademark or the pipe manufacturer's name.

5. Performance Requirements

5.1 The joint shall be designed to provide a permanent seal and shall be qualified in accordance with Section 8.

5.1.1 All surfaces of the joint upon or against which the gasket may bear shall be free of imperfections that could adversely affect the performance of the joint.

5.2 *Pressure Rating*—Designs not meeting the requirements of 6.2 shall be tested to verify that the hydrostatic design basis category for joint assemblies shall not be lower than the hydrostatic design basis category for pipe when tested under the same procedure. The hydrostatic design basis for this joint design shall be established on a representative size at a minimuim test level of 10 points and 2000 h in accordance with Test Method D 2837, except that the ends shall be restrained. Test pressure levels for establishing hydrostatic design basis shall be calculated on pipe minimum wall dimensions.

5.2.1 Joint designs shall require retesting under this section only if the joint design is changed or if the pipe compound is altered in any manner that produces a lower hydrostatic design basis category when compared with the compound used in the previous validation testing of the joint design.

---

[1] This specification is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.20 on Joining.

Current edition approved April 10, 1998. Published August 1998. Originally published as D 3139 – 73. Last previous edition D 3139 – 96a.

Copyright by the ASTM International
Wed Feb 02 01:55:51 2005

5.3 *Mechanical Joint*—The mechanical joint shall provide a pressure rating equal to or greater than that of the corresponding pipe.

5.3.1 *Internal Stiffener*—The pipe spigot shall have a wall thickness sufficient to withstand, without deformation or collapse, the compressive force exerted when the fitting is tightened. If the wall is not sufficient to withstand the compressive force, then a rigid tubular internal stiffener shall be used in conjunction with compressive-type mechanical joint fittings. A stiffener specified by the manufacturer for this purpose shall be used.

5.4 *Joint Deflection*—The joint shall provide a seal when the pipe spigot is deflected axially in the socket to the maximum unstressed limit permitted by dimensional clearance between the spigot and bell.

6. Dimensions, Mass, and Permissible Variations

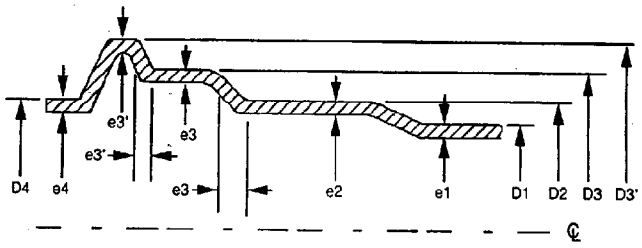
6.1 *Joint Dimensions and Tolerances*— The dimensions of the bell, socket, and plain end shall be in accordance with the manufacturer's standard design dimensions of the joint.

6.2 *Push-On Joint*—The minimum wall thickness of the bell at any point between the ring groove (annular gasket space) and the pipe barrel, shall conform to the dimension ratio requirements for the pipe barrel. The minimum wall thickness in the sealing portion of the ring groove and bell entry sections shall equal or exceed the minimum wall thickness requirements of the pipe barrel (see Fig. 1 or Fig. 2).

6.3 *Gasket Dimensions*—Gasket dimensions shall be in accordance with the manufacturer's standard design dimensions and tolerances. The gasket shall be of such size and shape as to provide an adequate compressive force against the spigot and socket after assembly to effect a positive seal under all combinations of permitted joint and gasket tolerances. The gasket shall be the sole element depended upon to make the joint flexible and water tight. The gasket shall be a continuous elastomeric ring.

7. Workmanship, Finish, and Appearance

7.1 The manufacturer of these joints shall produce joints meeting the requirements of this specification. Components of the joints shall be homogenous throughout and free from visible cracks, holes, foreign inclusions, or injurious defects.



C_L = center line
D_1 = average outside diameter - pipe
D_2 = average outside diameter - socket
D_3 = average outside diameter - sealing portion of the annular gasket space
D_3' = average outside diameter - locking portion of the annular gasket space
D_4 = average outside diameter - entry lip
e_1 = minimum wall thickness - pipe
e_2 = minimum wall thickness - socket
e_3 = minimum wall thickness - sealing portion of the annular gasket space
e_3' = minimum wall thickness - locking portion of the annular gasket space
e_4 = minimum wall thickness - entry lip
S_W = hydrostatic design stress
P_w = pressure rating shall be determined as follows:
$S_W = P_w(D - e)/2e$ (Method D 2837)
$e_1 = D_1[(2S_W/P_W) + 1]$
$e_2 = D_2/[(2S_W/P_W) + 1]$
$e_3 \geq e_1$
$e_3' \geq 0.9e1$
$e_4 \geq e_1$

FIG. 2 Relationship of Dimensions in 6.2

The components of the joints shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 The assembled joints shall pass the following laboratory qualifying tests. (For referee testing, standard laboratory conditions of 73°F and 50 % relative humidity will apply.)

8.1.1 *Internal Pressure Testing*—Laboratory hydrostatic pressure tests on joints shall be made on an assembly of two sections of pipe properly connected in accordance with the joint design and deflected to the limit defined in 5.4. No coatings, fillings, or packings, other than lubricants recommended in 4.2, shall be placed prior to water tightness tests. After the pipe sections are fitted together with the gasket or gaskets in place, the assembly shall be subjected to separate internal pressure tests, first at 50 % of rated pressure for 60 min, then at 2½ times the rated pressure for 60 min without leakage at either pressure for the duration of either test. The pressure shall then be continuously increased to the minimum short-term rupture requirement of the applicable pipe without

leakage. The pressure increase from 2½ times rated to minimum short-term rupture requirement shall occur over a 60 to 70-s period.

8.1.2 *Vacuum Test*—The assembled joint shall withstand a vacuum of 75-kPa gage (22 in. Hg) for 1 h with no leakage while in the auxiliary deflected position in accordance with 8.1.1.

9. Rejection and Rehearing

9.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and the seller. Under such agreement, minimum requirements shall not be lowered, nor tests omitted, substituted, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Certification

10.1 When specified in the purchase order or contract, the purchaser shall be furnished certification by affidavit that samples representing each lot of production have been either tested or inspected as directed in this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test or inspection results shall be furnished.

Standard Specification for Unmodified Poly(Vinylidene Fluoride) (PVDF) Molding Extrusion and Coating Materials[1]

This standard is issued under the fixed designation D 3222; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This specification covers melt processable molding and extrusion materials, as well as coating materials of poly(vinylidene fluoride) fluoroplastic, commonly abbreviated PVDF (or PVF_2 in scientific literature). This specification covers thermoplastic resin materials supplied in pellet or powder form.

1.2 This specification applies only to the virgin homopolymer prepared from vinylidene fluoride, not copolymers, reinforced, filled grades or special grades with additives or treatments for modification of attributes.

1.3 The tests involved are intended to provide information for specification of unmodified PVDF homopolymer resins. It is not the purpose of this specification to provide engineering data for design purposes.

1.4 PVDF fluoroplastics melt between 156 and 180°C (312 and 356°F) and are thermally stable up to about 370°C (698°F).

NOTE 1—**Warning:** Evolution of corrosive and toxic hydrogen fluoride can occur under certain conditions.

1.5 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

NOTE 2—PVDF exhibits polymorphism.[2] The type and extent of crystalline structure varies with the thermomechanical history of the sample. Specimens prepared by techniques different than prescribed in this specification could have properties that may vary from the values specified.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific precautionary statements are given in Note 1 and Section 10.

NOTE 3—There is no equivalent ISO standard for this specification. Information in this specification is technically equivalent to related information in ISO 12086-1 and ISO 12086-2.

TABLE 1 Classification of PVDF Resins

Property	Typical Values or Ranges		
	Type I		
	Grade 1	Grade 2	Type II
Specific Gravity	1.75 to 1.79	1.75 to 1.79	1.76 to 1.79
Peak Melting Endotherm, °C	156 to 162	162 to 170	164 to 180
Apparent Melt Viscosity,[A] Pa·s:			
High Viscosity	2800 to 3800	2800 to 3100	2500 to 4000
Medium Viscosity	2300 to 2800	1300 to 2800	1300 to 2500
Low Viscosity	...	500 to 1300	500 to 1300

[A] Reported for a shear rate of 100 s^{-1} determined by capillary rheometry at 232°C (450°F) using 0.027 radian (60°) entrance angle die with L/D of 15 and according to procedures of Test Method D 3835. Multiply the pascal second values by ten to obtain poise values.

2.2 *IEC and ISO Standards:*

ISO 12086-1 Plastics—Fluoropolymer Dispersion and Moulding and Extrusion Materials—Part 1: Designation and Basis for Specification[8]

ISO 12086-2 Plastics—Fluoropolymer Dispersion and Molding and Extrusion Materials—Part 2: Preparation of Test Specimens and Determination of Properties[8]

3. Terminology

3.1 *Definitions:*

3.1.1 For definitions of plastics terms used in this specification, see Terminology D 883.

3.2 *Units, Symbols, and Abbreviations:*

3.2.1 For units, symbols and abbreviations used in this specification see Practice E 380.

4. Classification

4.1 This specification covers two types[9] of natural, unmodified PVDF fluoroplastics supplied in pellet form for molding and extrusion, and in powder form for solutions, dispersions, or coatings.

4.1.1 *Type I*—PVDF fluoroplastics are polymerized in emulsion. Depending upon the polymerization conditions, the peak melting point of the resin can be varied between 156 and 170°C. The diameter of the primary particle isolated from the emulsion is typically less than 1 μm; the dried powder has an average agglomerate diameter range of 3 to 15 μm.

4.1.1.1 Two distinctly different Type I emulsion PVDF resins are available commercially. These are differentiated by peak melting endotherm values, as shown in Table 1, and this difference is the basis for subdividing Type I resins into Grades 1 and 2. Table 1 shows the melt viscosity ranges encompassing resin grades available from several sources and are provided for information purposes only.

4.1.2 *Type II*—PVDF fluoroplastics are polymerized in suspension. Peak melting temperatures of these resins range from 164 to 180°C. The particles isolated from suspension are spherical and range typically from 20 to 150 μm in diameter.

4.1.2.1 Type II resins are available commercially, and the data of Table 1 reflect ranges encompassing values typical for the properties of available grades.

4.2 A one-line system may be used to specify materials covered by this specification. The system uses predefined cells to refer to specific aspects of this specification, as illustrated below.

	Specification			
Standard Number Block	Type	Grade	Class	Special notes
Example: Specification D 3222 – 97	I	2	...	...

For this example (D 3222 – 97, I2), the line callout describes a PVDF resin polymerized in emulsion, having a specific gravity between 1.75 and 1.79, and a peak melting endotherm between 162 to 170°C. A comma is used as the separator between the Standard Number and the Type. Separators are not needed between the Type, Grade, and Class.[10] Provision for Special Notes is included so that other information, such as a preferred viscosity range, can be provided when required. When special notes are used, they should be preceded by a comma.

5. General Requirements

5.1 The material shall be of uniform composition and free of foreign matter to the contamination level agreed upon between the purchaser and seller.

6. Detail Requirements

6.1 *General Attributes*:

6.1.1 *Peak Melting Endotherm*—The material covered by this specification shall have a minimum peak melting endotherm for the type and class as shown in Table 1 when tested in accordance with Test Method D 3418. For Type I resins, this shall involve heating a solid specimen of 5 ± 1 mg from room temperature to 200°C at 10°C/min, maintaining the temperature at 200°C for 5 min, followed by cooling at a controlled rate of 10°C/min to about 30°C, then reheating at 10°C/min to 200°C. Record the peak melting endotherm during the second melting cycle.

6.1.1.1 *Temperature*—Test Type II resins likewise except that the maximum is 250°C.

6.1.2 *Specific Gravity*—A solid specimen of the material covered by this specification shall have the minimum specific gravity indicated in Table 1 (1.75 for Type I, Class 1 and 1.76 for all others) when tested in accordance with Test Methods D 792 or D 1505.

6.1.3 *Refractive Index*—The material covered in this specification shall have a refractive index of 1.42 when measured at the sodium D line at 25°C (77°F) in accordance with the refractometer procedure in Test Methods D 542, using specimens that have not been subjected to any processes which induce orientation of the polymer chains or crystal-lites.

[7] *Annual Book of ASTM Standards*, Vol 14.02.

[8] Available from American National Standards Institute, 11 W. 42nd St., 13th Floor, New York, NY 10036.

[10] See the ASTM *Form and Style for ASTM Standards*, available from ASTM Headquarters.

Copyright by the ASTM International
Wed Feb 02 01:57:18 2005

Compression-molded specimens at least 2-mm (0.079-in.) thick that have been quenched rapidly in water are preferred.

6.1.4 *Limiting Oxygen Index*—The material covered in this specification shall have a minimum limiting oxygen index of 42 when tested in accordance with Test Method D 2863.

NOTE 4—If a column with a restricted opening is used, the top of the specimen should be positioned 40 mm below the opening.

6.2 *Processing Related Attributes*:

6.2.1 *Flow Rate*—Materials conforming to this specification may be tested for melt flow rate according to Test Method D 1238, using 232°C and 21.6-kg load for medium or high melt viscosity grades; low melt viscosity grades may be tested at 232°C (450°F) using a 5 kg weight.

6.2.2 *Rheological Properties*—The preferred method for measuring flow characteristics is capillary rheometry. Thus rheological properties of the materials should be tested according to Test Method D 3835 at 232°C (450°F) using a die with an entrance angle of 60° (cone angle of 120°) and a minimum capillary L/D of 15. See Table 1.

6.3 *Mechanical Properties*:

6.3.1 *Tensile Properties*—The material covered in this specification shall have a tensile yield strength exceeding 36 MPa (5200 psi) at 23°C (74°F) and a minimum elongation at break of 10 % when tested according to Test Method D 638 at 51 mm (2 in.)/min, using Type I specimens 3.2-mm (0.125-in.) thick as specified in Test Method D 638. Condition in accordance with Procedure A of Test Method D 638, except that a minimum time of 16 h before testing is satisfactory. Preferably, compression-molded samples should be used (see Section 8), but injection molded specimens may be used, providing that the samples yield and rupture in the gage region and not near the heel. Specimens should be molded under conditions specified by the resin suppliers. Generally, injection molded specimens show low and variable elongation values compared to compression-molded specimens.

6.3.2 *Flexural Properties*—The material covered in this specification shall have a minimum flexural modulus of 1.38 GPa (190×10^3 psi) when tested according to Method I of Test Methods D 790, using 6.4-mm (0.25-in.) thick specimens prepared by injection molding under conditions specified by the resin supplier. Samples should be conditioned in accordance with Procedure A of Methods D 618 except that a minimum time of 16 h before testing is satisfactory. Alternatively, compression-molded samples may be used (see Section 8) and tested after the 16-h conditioning period.

6.3.3 *Impact Resistance*—The material covered in this specification shall have a minimum impact strength of 101.4 J/m (1.90 ft·lbf/in.) determined by Test Methods D 256 using 6.4-mm (0.25-in.) thick specimens prepared by injection molding under conditions specified by the manufacturer. Specimens shall be conditioned in accordance with the provisions of Procedure A of Methods D 618, except that the conditioning period prior to testing shall be at least 16 h. Alternatively, specimens may be compression-molded and tested after the conditioning period as specified above.

6.4 *Electrical Properties*:

6.4.1 *D-C Resistance*—The material covered in this specification shall have a d-c volume resistivity greater than $1.2\Omega \cdot m$ (1.2×10^{14} Ω·cm) when tested as a 0.76-mm (0.030-in.) compression-molded specimen (see Section 8) in accordance with Test Methods D 257.

6.4.2 *Dielectric Strength*—The material covered in this specification shall have a dielectric strength in air no less than 57 kV/mm (1280 V/0.001 in.) by the "short-time" method of Test Methods D 149 with 0.13-mm (0.05-in.) thick compression-molded specimens (see Section 8) tested in air using 25.4-mm (1-in.) Type 3 electrodes.

6.4.3 *Dielectric Constant*—The material covered in this specification shall have a dielectric constant less than 11.0 at 100 Hz and greater than 7.2 at 1 MHz when tested as a 3.2-mm (0.125-in.) thick compression-molded specimen (see Section 8) according to Test Methods D 150 at 23°C (73°F).

6.4.4 *Dissipation Factor*—The material covered in this specification shall have a dissipation factor of less than 0.045 at 100 Hz and less than 0.24 at 1 MHz when tested as 3.2-mm (0.125-in.) compression-molded specimens (see Section 8) according to Test Methods D 150 at 23°C (73°F).

NOTE 5—Since this material has very low water-absorption characteristics, maintenance of constant humidity during testing or specimen preparation is not necessary except as required for a specific test method. However, no moisture should be present in the resin when preparing specimens for testing. Heat the resin sample at 110°C (230°F) in an air-circulating oven until the adventitious moisture is removed.

7. Sampling

7.1 Materials shall be sampled in accordance with Practice D 1898. Adequate statistical sampling shall be considered an acceptable alternative.

8. Preparation of Compression Molded Specimens

8.1 *Equipment*:

8.1.1 Press with approximately 180 kN (20 ton) capacity and heating capability for maintaining platens between 220 and 240°C (428 to 464°F).

8.1.2 Two smooth chromium-finished plates with approximate dimensions $150 \times 250 \times 5$ mm ($10 \times 10 \times 0.02$ in.), or, if more appropriate to the press type, $150 \times 150 \times 5$ mm ($6 \times 6 \times 0.02$ in.).

8.1.3 Flat open-cavity steel molds, that is, frames, to provide the shape and thicknesses requisite for the specific tests.

8.1.4 Timing device.

8.1.5 Appropriate equipment to handle the hot mold assembly when removed from the press.

8.1.6 Balance and containers for weighing the resin samples.

8.1.7 Water-filled container to quench-cool the samples in the mold frame.

8.1.8 Aluminum foil approximately 0.1-mm thick (0.004-in.).

8.2 *Compression Molding Specimens Less Than 2 mm (0.08 in.)*:

8.2.1 For the given mold cavity establish, by initial trial preparations, the amount of material necessary to overfill slightly and yield a minimum flash after forming.

8.2.2 Place the appropriate amount of material in the center of the mold between thin sheets of polished aluminum foil.

Copyright by the ASTM International
Wed Feb 02 01:57:19 2005

8.2.3 Place the assembly between the chrome-finished plates.

8.2.4 Place the mold assembly in the press so that it is in contact with the hot platens, using a ram force that barely registers on the force gage and hold for a 5-min period. The temperature preferably should be 230°C (446°F) but may be as slow as 228°C (442°F) and as high as 232°C (450°F).

8.2.5 After the preheat period, slowly increase the ram force to 130 kN (30 000 lbf) and hold for 1 min.

8.2.6 Remove the sandwiched material and immediately quench in cold water.

8.2.7 After standing for 1 min, disassemble and remove the molded plaque from the frame.

NOTE 6—The alternative method of allowing the assembly to cool at ambient room temperature under a heavy weight, or under pressure in a cold press, may result in specimens having properties that may vary from values in specification tests.

8.2.8 If the mold shape is not appropriate for the test, cut test specimens from the molded sample.

NOTE 7—The edges of the specimen may affect performance in mechanical tests. Die-cutting is the preferred method to prepare such specimens; the cutting edges should be leveled and sharp.

8.3 *Compression Molding Specimens Thicker Than 2 mm (0.08 in.)*:

8.3.1 Pellets of PVDF can be compression-molded directly in thick sections without difficulty.

8.3.2 Powdered PVDF samples tend to entrap air when thick sections are molded under compression. Such specimens are not suitable for any tests in this specification. The preferred method to obtain bubble-free thick moldings involves preparation of thin compression-molded sheets, as described in 8.2, and a subsequent second molding cycle filling the thick section mold with several layers of the thin sheet specimens cut to fill the mold dimension. To assure complete filling, the stack of thin samples must be slightly higher than the mold cavity thickness.

9. Test Conditions

9.1 *Specific Gravity, Mechanical Properties, and Electrical Properties*:

9.1.1 Condition the molded test specimens in accordance with Procedure A of Practice D 618, except that the period shall be at least 16 h prior to test.

9.1.2 Conduct tests at the standard laboratory temperature of 23 ± 2°C (73.4 ± 3.6°F).

NOTE 8—PVDF is a partially crystalline polymer. Unless molded and conditioned equivalently for a sufficient period to assure consistent crystallinity, samples prepared by any other method may give variable results.

9.1.3 The specific gravity of two specimens cut from a compression-molded sample shall be determined according to Test Methods D 792 or D 1505. If the latter method is used, the tube should have a linear gradient over the range from about 1.65 to 1.90.

NOTE 9—Test Methods D 792 is particularly convenient, but care must be exercised to eliminate air bubbles that may be attached to the specimen upon immersion. Dipping the specimens in a very dilute solution (less than 0.1 weight percent) of an ammonium perfluorooctanoate surfactant minimizes this problem.

9.2 *Melting Temperature*—Determine the melting endotherm peak on the as-received resin sample according to Test Method D 3418 by differential scanning calorimetry under conditions given in 5.1.1. The test for melting endotherm peak requires no conditioning.

10. Handling

10.1 As is the case with any synthetic resin, it is advisable to wear a dust mask when handling large quantities of powder grades to prevent ingestion.

11. Packaging

11.1 The packing, packaging, and marking provisions of Practice D 3892 shall apply to this standard.

12. Precision and Bias

12.1 The precision and bias statements of ASTM test methods referenced herein apply to the specific tests required in this specification.

13. Keywords

13.1 extrusion materials; fluorohydrocarbon plastics; fluoropolymers; molding materials; polyvinylidene fluoride (PVDF)

SUMMARY OF CHANGES

This section identifies the location of selected changes to this specification. For the convenience of the user, Committee D-20 has highlighted those changes that may impact the use of this specification. This section may also include descriptions of the changes or reasons for the changes, or both.

D 3222 – 97:

(*1*) Changed SI statement (1.5).

(*2*) Added new Note 3.

(*3*) Added ISO 12086-01 and ISO 12086-02 and Terminology D 883 to list of referenced documents.

(*4*) Removed reference to Military specifications.

(*5*) Added new Sections 3, 3.1, and 3.2.

(*6*) In Table 1, changed Class 1 and 2 classifications to Grades 1 and 2 classifications.

(*7*) Changed 5.1.1.1 to reflect change from class to grade and qualified the inclusion of viscosity ranges in Table 1 as information only.

(*8*) In 5.2 changed one-line callout example to refer to D 3222 – 97.

D 3222 – 99:

(*1*) Revised the impact strength to 101.4 J/m (1.90 ft·lbf/in.) in 6.3.3.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: D 3307 – 00

An American National Standard

Standard Specification for Perfluoroalkoxy (PFA)-Fluorocarbon Resin Molding and Extrusion Materials[1]

This standard is issued under the fixed designation D 3307; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers melt processable molding and extrusion materials of PFA-perfluoro(alkoxy alkane) fluorocarbon resin. The materials are copolymers of TFE-fluorocarbon resins containing perfluoroalkoxy side chains.

1.2 This specification does not cover recycled plastics.[2]

1.3 The tests involved are intended to provide information for identifying the materials covered. It is not the function of this specification to provide engineering data for design purposes. Specimens prepared by injection molding or extrusion could yield test results that may vary from the values in this specification.

1.4 The values stated in SI units[3] are to be regarded as the standard. The values given in parentheses are for information only.

1.5 The following precautionary caveat pertains only to the test methods portions, Sections 8 and 9 of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—This specification, ISO 12086–1(1995), and ISO 12086–2(1995) differ in approach or detail. Data obtained using either may not be technically equivalent.

to refer to specific aspects of this specification, as illustrated as follows:

Specification				
Standard Number Block	Type	Grade	Class	Special Notes
Example: Specification D 3307 – 98,	I			

In this standard, the only specifications are type; no grade or class is required. A comma is used as the separator between the standard number and the type. Separators are not needed between the type, grade, and class.[10] Provision for special notes is included so that other information can be provided when required. An example would be in Specification D 3295 where dimensions and tolerances are specified for each AWG size within type and class. When special notes are used, they should be preceded by a comma.

5. General Requirements

5.1 The materials shall be of uniform composition and so prepared as to conform to the requirements of this specification.

5.2 The materials described in this specification shall be free of foreign matter to such a contamination level as may be agreed upon between the purchaser and the seller.

6. Detail Requirements

6.1 The materials covered by this specification shall conform to the requirements prescribed in Table 1 and Table 2 when tested by the procedures specified herein. Table 2 lists those tests requiring a specimen molded as described in 9.1.

7. Sampling

7.1 Sampling shall be statistically adequate to satisfy the requirements of 10.4.

8. Number of Tests

8.1 One set of test specimens as prescribed in Section 9 shall be considered sufficient for testing each sample. The average result of the specimens tested shall conform to the requirements of this specification.

9. Test Methods

9.1 *Test Specimens*:

9.1.1 Prepare a molded sheet 1.5 ± 0.25-mm (0.060± 0.010-in.) thick. Use a picture-frame-type chase having a suitable blanked-out section and thickness to produce the desired sheet. Use clean aluminum foil, 0.13 to 0.18 mm (0.005 to 0.007 in.) thick, in contact with the resin. A high temperature mold release agent may be sprayed on the aluminum foil to help prevent the foil from sticking to the sheet. Use steel molding plates at least 1.0 mm (0.040 in.) thick and of an area adequate to cover the chase.

9.1.2 Lay down and smoothly cover one plate with a sheet of aluminum foil. Place the mold chase on top of this assembly. Place within the mold chase sufficient molding material to produce the required sheet in such manner that the polymer charge is a mound in the middle of the chase. Place a second sheet of aluminum foil on top of the granules and add the top mold plate. Place the assembly in a compression molding press having platens that have been heated to 380 ± 5°C (716 ± 10°F).

9.1.3 Bring the press platens to incipient contact with the mold assembly. Hold for 2 to 4 min without pressure. Apply approximately 1 MPa (145 psi) and hold for 1 to 1.5 min. Then apply 2 to 4 MPa (290 to 580 psi) and hold for 1 to 1.5 min. Maintain the press at 380 ± 5°C (716 ± 10°F) during these steps. Remove the assembly from the press and place between two 20 ± 7-mm (0.75 ± 0.25-in.) steel plates whose temperature is less than 40°C (104°F).

9.1.4 When the sheet is cool enough to touch (about 50 to 60°C (122 to 140°F)), remove the aluminum foil from the sheet. (If the sheet is allowed to cool to room temperature, the aluminum foil cannot be pulled free.)

9.2 *Conditioning*:

9.2.1 For tests of specific gravity, tensile properties, and electrical properties, condition the molded test specimens in accordance with Procedure A of Practice D 618 for a period of at least 4 h prior to test. The other tests require no conditioning.

9.2.2 Conduct tests at the Standard Laboratory Temperature of 23 ± 2°C (73.4 ± 3.6°F) for determination of specific gravity, tensile properties, and electrical properties only. Since the resin does not absorb water, the maintenance of constant humidity during testing is not necessary. Conduct tests for melt flow rate and melting endotherm under ordinary laboratory conditions.

9.3 *Melt Flow Rate*—Determine the melt flow rate in

[10] See *ASTM Form and Style Manual.*

accordance with Test Method D 1238, Test Method A or B, with a temperature of 372 ± 1°C and using a total load, including piston, of 5000 g. The same requirements apply for the use of corrosion-resistant alloy for the barrel lining, orifice, and piston tip.

9.4 *Melting Endotherm Peak*:

9.4.1 Determine the melting endotherm peak with a different thermal analyzer. Place a 20-mg specimen in a 4-mm tube with a thermocouple. Premelt the specimen at 325°C, and push the thermocouple into intimate contact with the melt. Cool the sample in air. Run the differential thermal analysis at 10°C/min with glass beads as a reference to a maximum temperature of 350°C. Extend straight lines down tangent to both sides of the melting endotherm, and take the temperature at which the lines intersect (peak minimum) as the melting endotherm peak.

9.4.2 *Precision*—The single instrument precision of the differential thermal analysis applied to this material is± 1.2°C (2S) as defined in Practice E 177.

9.4.3 Other thermal techniques capable of measuring the melting endotherm giving equivalent results may be used, such as Test Method D 4591.

9.5 *Specific Gravity*—Cut two specimens from the compression molded sheet and test in accordance with Test Method D 792 or Test Method D 1505. If the latter is used, the tube should have a linear gradient over the range from about 2.10 to 2.19.

9.6 *Tensile Properties*—Cut five specimens with the microtensile die shown in Fig. 1, which is exactly the same as Fig. 1 of Test Method D 1708. The die shall be of the steel-rule type of curvature of 5 ± 0.5-mm (0.20 ± 0.02-in.) type. Determine the tensile properties in accordance with the procedures described in Test Method D 638, except that the specimens used shall be as detailed above, the initial jaw separation shall be 22 ± 0.13 mm (0.866 ± 0.005 in.), and the speed of testing shall be 50 mm/min (2 in./min). Clamp the specimens with essentially equal lengths in each jaw. Determine the elongation from the chart, expressing it as a percentage of the initial jaw separation. Details appear in the Tensile Properties section of Specification D 2116.

9.7 *Dielectric Constant and Dissipation Factor*—Determine dielectric constant and dissipation factor on three specimens, each 101.6 mm (4 in.) in diameter in accordance with Test Methods D 150. Testing shall be at 10^2 Hz and 10^6 Hz.

10. Inspection and Certification

10.1 Inspection and certification of the material supplied with reference to a specification based on this classification system shall be for conformance to the requirements specified herein.

10.2 *Lot*—Acceptance shall be the basis on which acceptance or rejection of the lot is made. The lot acceptance inspection shall consist of melting endotherm peak temperature and melt flow rate.

10.3 Periodic check inspection with reference to a specification based on this classification system shall consist of the test for all requirements of the material in accordance with this specification.

10.4 Certification shall be that the material was manufactured by a process in statistical control, sampled, tested, and inspected in accordance with this classification system, and that the average values for the lot meet the requirements of this specification (line callout).

10.5 A report of test results shall be furnished when requested. The report shall consist of results of the lot-acceptance inspection for the shipment and the results of the most recent periodic-check inspection.

11. Packaging and Package Marking

11.1 All packing, packaging, and marking provisions of Practice D 3892 shall apply to this specification.

12. Precision and Bias [11]

12.1 A round robin was conducted in 1985–1986 in accordance with Practice E 691, involving seven materials tested by six laboratories (see Table 3). For each material, the sheeting from which the test specimens were to be cut was obtained from one source. Using a steel rule die, one set of test specimens for each laboratory was cut by one of the laboratories. Sheeting and a duplicate die were furnished each participating laboratory and used to cut a second set of test specimens. Each test result was the average of five individual determinations. Each laboratory obtained four test results on each material, two test results each on the specimens furnished and two on the specimens cut by the laboratory doing the testing.

12.1.1 The properties used in the analysis are tensile strength and elongation at break. The stress-strain curves of the fluorocarbon polymers (but not the fluoropolymers: modified ETFE and poly(vinylidene fluoride), PVDF) are similar in shape. Data on ETFE and PVDF, therefore, were excluded from the analysis used for this precision and bias statement but are available for use in precision and bias statements and are to be included in the research report at ASTM. Based on advice from experts in statistical analysis of round-robin data, and since use of fillers is excluded in the applicable standards, information from the testing on glass-fiber filled PTFE also is not included in Table 3. In addition, the experts advised that information from the samples cut in one laboratory and tested by all the laboratories should not be included in Table 3. The data are available in the report.

NOTE 2—**Caution:** The following explanations of I_r and I_R (12.3-12.3.3) are intended only to present a meaningful way of considering the approximate precision of this specification. The data in Table 3 should not be applied rigorously to acceptance or rejection of material, as those data are specific to the round robin and may not be representative of other lots, conditions, materials, or laboratories.

12.2 Users of this test method should apply the principles outlined in Practice E 691 to generate data specific to their laboratory and materials, or between specific laboratories. The principles of 12.3-12.3.3 would then be valid for such data.

12.3 *Concept of I_r and I_R*—If CV_r and CV_R have been calculated from a large enough body of data, and for test results that were averages from testing five specimens:

[11] Supporting data are available from ASTM Headquarters. Request RR:D20-1067.

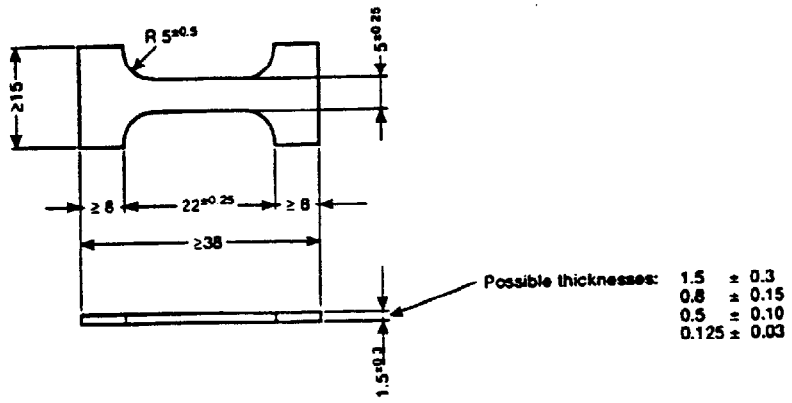
STEEL RULE DIE
(Inside dimensions for die are the same as test specimen)
Die to be sharpened
As shown in "A-A"



TEST SPECIMEN

NOTE 1—All dimensions are in millimetres.

FIG. 1 Microtensile Die and Test Specimen

12.3.1 *Repeatability (I_r)*—In comparing two test results for the same material, obtained by the same operator using the same equipment on the same day, the two test results should be judged not equivalent if they differ by more than the I_r value for that material.

12.3.2 *Reproducibility (I_R)*—In comparing two test results for the same material, obtained by different operators using different equipment on different days, the two test results should be judged not equivalent if they differ by more than the I_R value for that material.

12.3.3 Any judgment in accordance with 12.3.1 and 12.3.2 would have an approximate 95 % (0.95) probability of being correct.

12.4 *Bias*—Bias is systematic error that contributes to the

SUMMARY OF CHANGES

This section identifies the location of selected changes to this specification. For the convenience of the user, Committee D20 has highlighted those changes that may impact the use of this specification. This section may also include descriptions of the changes or reasons for the changes, or both.

D 3307–98:

(*1*) Added perfluoro(alkoxy alkane) to Section 1 and to the title.

(*2*) Inserted in 1.3: This section does not cover recycled plastics.

(*3*) Inserted Note 1 to include ISO equivalency statement.

(*4*) Renumbered Section 1 and added Footnotes 2 and 3.

(*5*) Inserted in 2.1: Test Methods D 1238, D 1708, and D 4591; Guide D 5033; IEEE/ASTM SI 10; and ISO 12086–1 and 2.

(*6*) In 2.1, updated footnote information.

(*7*) In 4.2, upgraded callout section to reflect this specification.

(*8*) In 9.3, added reference to Test Method D 1238 and eliminated reference to Specification D 2116.

(*9*) In 9.4, added reference to Test Method D 4591.

(*10*) In 9.6, upgraded dimensions to reflect ISO tensile strength die and replaced Fig. 1 with ISO equivalent.

(*11*) In 12.1, at the end of first sentence added reference to Table 3.

(*12*) In 7.1, removed incorrect wording.

(*13*) In 9.1, added qualification statement.

(*14*) Added Section 13, Keywords.

(*15*) Added Summary of Changes.

(*16*) In Section 2, changed Tensile Strength, Type II, from 3800 psi to 3625 psi and changed 26.20 MPa to 25.0 MPa.

D 3307 – 00:

(*1*) Added Terminologies D 883 and D 1600 to Section 2.

(*2*) Deleted Test Method D 1708, Practice D 1898, and Specification D 2116 from Section 2.

(*3*) Added Section 3 on Terminology, including a definition for *lot*.

(*4*) Renumbered all following sections accordingly.

(*5*) Deleted 6.1 and replaced with upgraded sampling process (now 7.1).

(*6*) Added three additional types to Table 1.

(*7*) Added three additional types to Table 2.

(*8*) Changed Section 9, Retest and Rejection, to Section 10, Inspection and Certification, with appropriate subheadings.

(*9*) Added footnotes to Tables 1 and 2 referencing sections within this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: D 3311 – 94

An American National Standard

Standard Specification for Drain, Waste, and Vent (DWV) Plastic Fittings Patterns[1]

This standard is issued under the fixed designation D 3311; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification provides standard fitting geometries and laying lengths for plastic fittings intended for use in drain, waste, and vent applications.

1.2 Fittings meeting the requirements of this standard specification are designed for use with outside diameter controlled pipe. The inside diameter can vary significantly as the wall thickness and outside diameter varies and therefore is not suitable for use as a fitting socket.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information only.

2. Referenced Documents

2.1 *ASTM Standards:*

D 2661 Specification for Acrylonitrile-Butadiene-Styrene (ABS) Schedule 40 Plastic Drain, Waste, and Vent Pipe Fittings[2]

D 2665 Specification for Poly(Vinyl Chloride) (PVC) Plastic Drain, Waste, and Vent Pipe and Fittings[2]

D 2749 Symbols for Dimensions of Plastic Pipe Fittings[2]

F 628 Specification for Acrylonitrile-Butadiene-Styrene (ABS) Schedule 40 Plastic Drain, Waste, and Vent Pipe with a Cellular Core[2]

F 891 Specification for Coextruded Poly(Vinyl Chloride) (PVC) Plastic Pipe with a Cellular Core[2]

3. Requirements

3.1 Fittings shall conform to the geometries and laying lengths as shown in Tables 1-42 and Fig. 1. Tolerances shall be ±1/16 in. unless otherwise specified.

3.2 Spigot and hub dimensions shall conform to the requirements of the referencing standard.

3.3 The exact outside shape of a fitting is not determined by the outline drawings shown in this specification but rather by the socket dimensions, wall thickness requirements, waterway, laying lengths, and any other critical dimensions that may be specified.

3.4 The pitch of sockets for patterns with 90° angles (except vent fittings) shall be ¼ in./ft or 1° 12 min.

3.5 On double reducing sanitary tees, the *G2* dimension on branches will be calculated on the larger size and centerlines shall remain the same for both branches.

3.6 All other dimensions, materials and property requirements shall be in conformance with the referencing standard.

4. Keywords

4.1 DWV; fittings; plastic; Schedule 40; thermoplastic

[A]Non-reducing double sanitary tees are for vent use only.
[B]This dimension is a minimum with no upper maximum limit.
[C]Combination Wye and ⅛ bend is assembled from two standard fittings.

Designation: D 3517 – 01

Standard Specification for "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pressure Pipe[1]

This standard is issued under the fixed designation D 3517; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This specification covers machine-made fiberglass pipe, 8 in. (200 mm) through 144 in. (3700 mm), intended for use in water conveyance systems which operate at internal gage pressures of 250 psi (1.72 MPa) or less. Both glass-fiber-reinforced thermosetting-resin pipe (RTRP) and glass-fiber-reinforced polymer mortar pipe (RPMP) are fiberglass pipes. The standard is suited primarily for pipes to be installed in buried applications, although it may be used to the extent applicable for other installations such as, but not limited to, sliplining and rehabilitation of existing pipelines.

NOTE 1—For the purposes of this standard, polymer does not include natural polymers.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

NOTE 2—There is no similar or equivalent ISO standard.

1.3 The following safety hazards caveat pertains only to the test methods portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Wed Feb 02 01:59:01 2005

reinforcements, or both, applied to the exterior surface of the pipe structural wall.

3.2.2 *fiberglass pipe*—a tubular product containing glass-fiber reinforcements embedded in or surrounded by cured thermosetting resin. The composite structure may contain aggregate, granular, or platelet fillers, thixotropic agents, pigments, or dyes. Thermoplastic or thermosetting liners or coatings may be included.

3.2.3 *liner*—a resin layer, with or without filler, or reinforcement, or both, forming the interior surface of the pipe.

3.2.4 *qualification test*—one or more tests used to prove the design of a product. Not a routine quality control test.

3.2.5 *reinforced polymer mortar pipe (RPMP)*—a fiberglass pipe with aggregate.

3.2.6 *reinforced thermosetting resin pipe (RTRP)*—a fiberglass pipe without aggregate.

4. Classification

4.1 *General*—This specification covers fiberglass pressure pipe defined by raw materials in the structural wall (type) and liner, surface layer material (grade), operating pressure (class), and pipe stiffness. Table 1 lists the types, liners, grades, classes, and stiffnesses that are covered.

NOTE 3—All possible combinations of types, liners, grades, classes, and stiffnesses may not be commercially available. Additional types, liners, grades, and stiffnesses may be added as they become commercially available. The purchaser should determine for himself or consult with the manufacturer for the proper class, type, liner, grade and stiffness of pipe to be used under the installation and operating conditions that will exist for the project in which the pipe is to be used.

4.2 *Designation Requirements*—The pipe materials designation code shall consist of the standard designation, ASTM D 3517, followed by type, liner, and grade in Arabic numerals, class by the letter C and two or three Arabic numerals, and pipe stiffness by a capital letter. Table 1 presents a summary of the designation requirements. Thus, a complete material code shall consist of ASTM D 3517... three numerals, C ... and two or three numerals, and a capital letter.

NOTE 4—Examples of the designation are as follows: *(1)* ASTM D 3517-1-1-3-C50-A for glass-fiber reinforced aggregate and polyester resin mortar pipe with a reinforced thermoset liner and an unreinforced polyester resin and sand surface layer, for operation at 50 psi (345 kPa), and having a minimum pipe stiffness of 9 psi (62 kPa), *(2)* ASTM D 3517-4-2-6-C200-C for glass-fiber reinforced epoxy resin pipe with a non-reinforced thermoset liner, no surface layer, for operation at 200 psi (1380 kPa), and having a minimum pipe stiffness of 36 psi (248 kPa).

NOTE 5—Although the "Form and Style for ASTM Standards" manual requires that the type classification be roman numerals, it is recognized that companies have stencil cutting equipment for this style of type, and it is therefore acceptable to mark the product type in arabic numbers.

5. Materials and Manufacture

5.1 *General*—The resins, reinforcements, colorants, fillers, and other materials, when combined as a composite structure, shall produce a pipe that shall meet the performance requirements of this specification.

5.2 *Wall Composition*—The basic structural wall composition shall consist of thermosetting resin, glass fiber reinforcement, and, if used, an aggregate filler.

5.2.1 *Resin*—A thermosetting polyester or epoxy resin, with or without filler.

5.2.2 *Reinforcement*—A commercial grade of E-type glass fibers with a finish compatible with the resin used.

5.2.3 *Aggregate*—A siliceous sand conforming to the requirements of Specification C 33, except that the requirements for gradation shall not apply.

NOTE 6—Fiberglass pipe intended for use in the transport of potable water should be evaluated and certified as safe for this purpose by a testing agency acceptable to the local health authority. The evaluation should be in accordance with requirements for chemical extraction, taste, and odor that are no less restrictive than those included in National Sanitation Foundation (NSF) Standard 61. The seal or mark of the laboratory making the evaluation should be included on the fiberglass pipe.

5.3 *Liner and Surface Layers*—Liner or surface layer, or both, when incorporated into or onto the pipe, shall meet the

TABLE 1 General Designation Requirements for Fiberglass Pressure Pipe

Designation Order	Property	Cell Limits[A]								
1	Type	1 glass-fiber-reinforced thermosetting polyester[B] resin mortar (RPMP polyester[B])		2 glass-fiber-reinforced thermosetting polyester[B] resin (RTRP polyester[B])		3 glass-fiber-reinforced thermosetting epoxy resin mortar (RPMP epoxy)			4 glass-fiber-reinforced thermosetting epoxy resin (RTRP epoxy)	
2	Liner	1 reinforced thermoset liner		2 non-reinforced thermoset liner		3 thermoplastic liner			4 no liner	
3	Grade	1 polyester[B] resin surface layer—reinforced	2 polyester[B] resin surface layer—non-reinforced	3 polyester[B] resin and sand surface layer nonreinforced		4 epoxy resin surface layer—reinforced		5 epoxy resin surface layer—non-reinforced		6 no surface layer
4	Class[C]	C50	C75	C100	C125	C150	C175	C200	C225	C250
5	Pipe Stiffness psi (kPa)	A 9 (62)		B 18 (124)			C 36 (248)		D 72 (496)	

NOTE 1— [A] The cell-type format provides the means of identification and specification of piping materials. This cell-type format, however, is subject to misapplication since unobtainable property combinations can be selected if the user is not familiar with non-commercially available products. The manufacturer should be consulted.

NOTE 2— [B] For the purposes of this standard, polyester includes vinyl ester resins.

NOTE 3— [C] Based on operating pressure in psig (numerals).

Wed Feb 02 01:59:09 2005

structural requirements of this specification.

5.4 *Joints*—The pipe shall have a joining system that shall provide for fluid tightness for the intended service condition.

5.4.1 *Unrestrained*—Pipe joints capable of withstanding internal pressure but not longitudinal forces.

5.4.1.1 *Coupling or Bell-and-Spigot Gasket Joints*, with a groove either on the spigot or in the bell to retain an elastomeric gasket that shall be the sole element of the joint to provide watertightness. For typical joint detail see Fig. 1.

5.4.1.2 *Mechanical Couplings*..

5.4.2 *Restrained*—Pipe joints capable of withstanding internal pressure and longitudinal forces.

5.4.2.1 Joints similar to those in 5.4.1.1 with supplemental restraining elements.

5.4.2.2 *Butt Joint*, with laminated overlay.

5.4.2.3 *Bell-and-Spigot*, with laminated overlay.

5.4.2.4 *Bell-and-Spigot*, adhesive bonded.

5.4.2.5 *Flanged*.

5.4.2.6 *Mechanical*.

NOTE 7—Other types of joints may be added as they become commercially available.

5.5 *Gaskets*—Elastomeric gaskets when used with this pipe shall conform to the requirements of Specification F 477.

6. Requirements

6.1 *Workmanship*:

6.1.1 Each pipe shall be free from all defects including indentations, delaminations, bubbles, pinholes, cracks, pits, blisters, foreign inclusions, and resin-starved areas that due to their nature, degree, or extent, detrimentally affect the strength and serviceability of the pipe. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

6.1.2 The inside surface of each pipe shall be free of bulges, dents, ridges, and other defects that result in a variation of inside diameter of more than ⅛ in. (3.2 mm) from that obtained on adjacent unaffected portions of the surface. No glass fiber reinforcement shall penetrate the interior surface of the pipe wall.

6.1.3 Joint sealing surfaces shall be free of dents, gouges, and other surface irregularities that will affect the integrity of the joints.

6.2 *Dimensions*:

6.2.1 *Pipe Diameters*—Pipe shall be supplied in the nominal diameters shown in Table 2 or Table 3. The pipe diameter tolerances shall be as shown in Table 2 or Table 3, when measured in accordance with 8.1.1.

6.2.2 *Lengths*—Pipe shall be supplied in nominal lengths of 10, 20, 30, 40, and 60 ft. (3.05, 6.10, 9.15, 12.19, and 18.29 m). The actual laying length shall be the nominal length ±2 in. (±51 mm), when measured in accordance with 8.1.2. At least 90 % of the total footage of any one size and class, excluding special order lengths, shall be furnished in the nominal lengths specified by the purchaser. Random lengths, if furnished, shall not vary from the nominal lengths by more than 5 ft (1.53 m) or 25 %, whichever is less.

6.2.3 *Wall Thickness*—The average wall thickness of the pipe shall not be less than the nominal wall thickness published in the manufacturer's literature current at the time of purchase, and the minimum wall thickness at any point shall not be less than 87.5 % of the nominal wall thickness when measured in accordance with 8.1.3.

6.2.4 *Squareness of Pipe Ends*—All points around each end of a pipe unit shall fall within ±¼ in. (±6.4 mm) or ±0.5 % of the nominal diameter of the pipe, whichever is greater, to a plane perpendicular to the longitudinal axis of the pipe, when measured in accordance with 8.1.4.

6.3 *Soundness*—Unless otherwise agreed upon between purchaser and supplier, test each length of pipe up to 54 in. (1370 mm) diameter hydrostatically without leakage or cracking, at the internal hydrostatic proof pressures specified for the applicable class in Table 4, when tested in accordance with 8.2. For sizes over 54 in., the frequency of hydrostatic leak tests shall be as agreed upon by purchaser and supplier.

6.4 *Hydrostatic Design Basis*:

6.4.1 *Long-Term Hydrostatic Pressure*—The pressure classes shall be based on long-term hydrostatic pressure data obtained in accordance with 8.3 and categorized in accordance with Table 5. Pressure classes are based on extrapolated strengths at 50 years. For pipe subjected to longitudinal loads or circumferential bending, the effect of these conditions on the hydrostatic design pressure, classification of the pipe must be considered.

6.4.2 *Control Requirements*—Test pipe specimens periodically in accordance with Practice D 2992.

NOTE 8—Hydrostatic design basis (HDB-extrapolated value at 50 years) determined in accordance with Procedure A of Practice D 2992, may be substituted for the Procedure B evaluation required by 8.3. It is generally accepted that the Procedure A HDB value times 3 is equivalent to the Procedure B HDB value.

6.5 *Stiffness*—Each length of pipe shall have sufficient strength to exhibit the minimum pipe stiffness ($F/\Delta y$) specified in Table 6, when tested in accordance with 8.4. At deflection level A per Table 7, there shall be no visible damage in the test specimen evidenced by surface cracks. At deflection level B per Table 7, there shall be no indication of structural damage as evidenced by interlaminar separation, separation of the liner or surface layer (if incorporated) from the structural wall, tensile failure of the glass fiber reinforcement, and fracture or buckling of the pipe wall.

NOTE 9—This is a visual observation (made with the unaided eye) for quality control purposes only and should not be considered a simulated service test. Table 7 values are based on an in-use long-term deflection limit of 5 % and provide an appropriate uniform safety margin for all pipe stiffnesses. Since the pipe stiffness values ($F/\Delta y$) shown in Table 6 vary, the percent deflection of the pipe under a given set of installation

[A] Inside diameters other than those shown shall be permitted by agreement between purchaser and supplier.
[B] Values are taken from International Standards Organization documents. Parentheses indicate non-preferred diameters.

conditions will not be constant for all pipes. To avoid possible misapplication, take care to analyze all conditions which might affect performance of the installed pipe.

6.5.1 For other pipe stiffness levels, appropriate values for Level A and Level B deflections (Table 7) may be computed as follows:

$$\text{Level A at new PS} = \left(\frac{72}{\text{new PS}}\right)^{0.33} (9) \qquad (1)$$

$$\text{Level B at new PS} = \text{new Level A} \div 0.6$$

6.5.2 Since products may have use limits of other than 5 % long-term deflection, Level A and Level B deflections (Table 7) may be proportionally adjusted to maintain equivalent in-use safety margins. For example, a 4 % long-term limiting deflection would result in a 20 % reduction of Level A and Level B deflections, while a 6 % limiting deflection would result in a 20 % increase in Level A and Level B deflection values. However, minimum values for Level A and Level B deflections shall be equivalent to strains of 0.6 and 1.0 % respectively (as computed by Eq X1.4 in Appendix X1 of Specification D 3262).

6.6 *Hoop-Tensile Strength*—All pipe manufactured under this specification shall meet or exceed the hoop-tensile strength shown for each size and class in Table 8, when tested in accordance with 8.5.

6.6.1 *Alternative Requirements*—When agreed upon between the purchaser and the supplier, the minimum hoop-tensile strength shall be as determined in accordance with 8.5.1.

6.7 *Joint Tightness*—The pipe joint shall meet the Laboratory Performance Requirements section of Specification D 4161. Restrained rigid joints (see 5.4.2.2, 5.4.2.3, 5.4.2.4, and 5.4.2.5) shall be exempt from angular deflection requirements.

6.8 *Longitudinal Strength*:

6.8.1 *Beam Strength*—For pipe sizes up to 27 in. the pipe shall withstand, without failure, the beam loads specified in Table 9, when tested in accordance with 8.6.1. For pipe sizes larger than 27 in., and alternatively for smaller sizes, adequate beam strength is demonstrated by tension and compression tests conducted in accordance with 8.6.2 and 8.6.3, respectively, for pipe wall specimens oriented in the longitudinal direction, using the minimum tensile and compressive strength specified in Table 9.

6.8.2 *Longitudinal Tensile Strength*—All pipe manufactured under this specification shall meet or exceed the longitudinal tensile strength shown for each size and class in Table 10, when tested in accordance with 8.6.2.

	Nominal Pipe Stiffness, psi			
	9	18	36	72
Level A	18 %	15 %	12 %	9 %
Level B	30 %	25 %	20 %	15 %

NOTE 10—The values listed in Table 10 are the minimum criteria for products made to this standard. The values may not be indicative of the axial strength of some products, or of the axial strength required by some installation conditions and joint configurations.

6.8.3 Conformance to the requirements of 6.8.1 shall satisfy the requirements of 6.8.2 for those pipe sizes and classes where the minimum longitudinal tensile strength values of Table 9 are equal to the values of Table 10. Conformance to the requirements of 6.8.2 shall satisfy the longitudinal tensile strength requirements of 6.8.1.

7. Sampling

7.1 *Lot*—Unless otherwise agreed upon between the purchaser and the supplier, one lot shall consist of 100 lengths of each type, grade, and size of pipe produced.

7.2 *Production Tests*—Select one pipe at random from each lot and take one specimen from the pipe barrel to determine conformance of the material to the workmanship, dimensional, and stiffness, and strength requirements of 6.1, 6.2, 6.5, and 6.6, respectively. Unless otherwise agreed upon between purchaser and supplier, all pipes (up to 54-in. (1370-mm) diameter) shall meet the soundness requirements of 6.3.

7.3 *Qualification Tests*—Sampling for qualification tests (see section 3.2.4) is not required unless otherwise agreed upon between the purchaser and the supplier. Qualification tests, for which a certification and test report shall be furnished when requested by the purchaser include the following:

7.3.1 *Long-Term Hydrostatic Pressure Test.*

7.3.2 *Joint-Tightness Test* (See 6.7).

7.3.3 *Longitudinal-Strength Test*, including:

7.3.3.1 Beam strength and

7.3.3.2 Longitudinal tensile strength.

7.4 *Control Tests*—The following test is considered a control requirement and shall be performed as agreed upon between the purchaser and the supplier:

7.4.1 *Soundness Test*—60-in. (1520-mm) diameter pipe and larger.

7.4.2 Perform the sampling and testing for the control requirements for hydrostatic design basis at least once every two years.

7.5 For individual orders conduct only those additional tests and numbers of tests specifically agreed upon between the purchaser and the supplier.

8. Test Methods

8.1 *Dimensions*:

8.1.1 *Diameters*:

8.1.1.1 *Inside Diameter*—Take inside diameter measurements at a point approximately 6 in. (152 mm) from the end of the pipe section using a steel tape or an inside micrometer with graduations of 1/16 in. (1 mm) or less. Make two 90° opposing measurements at each point of measurement and average the readings.

8.1.1.2 *Outside Diameter*—Determine in accordance with Test Method D 3567.

8.1.2 *Length*—Measure with a steel tape or gage having graduations of 1/16in. (1 mm) or less. Lay the tape or gage on or inside the pipe and measure the overall laying length of the pipe.

8.1.3 *Wall Thickness*—Determine in accordance with Test Method D 3567.

8.1.4 *Squareness of Pipe Ends*—Rotate the pipe on a mandrel or trunnions and measure the runout of the ends with a dial indicator. The total indicated reading is equal to twice the distance from a plane perpendicular to the longitudinal axis of the pipe. Alternatively, when squareness of pipe ends is rigidly fixed by tooling, the tooling may be verified and reinspected at frequent enough intervals to ensure that the squareness of the pipe ends is maintained within tolerance.

8.2 *Soundness*—Determine soundness by a hydrostatic proof test procedure. Place the pipe in a hydrostatic pressure testing machine that seals the ends and exerts no end loads. Fill the pipe with water, expelling all air, and apply internal water pressure at a uniform rate not to exceed 50 psi (345 kPa)/s until the Table 4 test pressure specified in accordance with 6.3 is reached. Maintain this pressure for a minimum of 30 s. The

Procedure B of Practice D 2992, with the following exceptions permitted:

8.3.1 Test at ambient temperatures between 50 and 110°F (10 and 43.5°C) and report the temperature range experienced during the tests.

NOTE 11—Tests indicate no significant effects on long-term hydrostatic pressure within the ambient temperature range specified.

8.3.2 Determine the hydrostatic design basis for the glass fiber reinforcement in accordance with the method in Annex A1.

8.3.3 Calculate the long-term hydrostatic pressure and categorize by class in accordance with Table 5. A1.6 explains how to calculate the long-term hydrostatic pressure.

8.4 *Stiffness*—Determine the pipe stiffness ($F/\Delta y$) at 5 % deflection for the specimen, using the apparatus and procedure of Test Method D 2412, with the following exceptions permitted:

8.4.1 Measure the wall thickness to the nearest 0.01 in. (0.25 mm).

8.4.2 Load the specimen to 5 % deflection and record the load. Then load the specimen to deflection level A per Table 7 and examine the specimen for visible damage evidenced by surface cracks. Then load the specimen to deflection level B per Table 7 and examine for evidence of structural damage, as evidenced by interlaminar separation, separation of the liner or surface layer (if incorporated) from the structural wall, tensile failure of the glass fiber reinforcement, and fracture or buckling of the pipe wall. Calculate the pipe stiffness at 5 % deflection.

8.4.3 For production testing, test only one specimen to determine the pipe stiffness.

8.4.4 The maximum specimen length shall be 12 in. (305 mm), or the length necessary to include stiffening ribs, if they are used, whichever is greater.

NOTE 12—As an alternative to determining the pipe stiffness using the apparatus and procedure of Test Method D 2412 the supplier may submit to the purchaser for approval a test method and test evaluation on Test Method D 790, accounting for the substitution of curved test specimens and measurement of stiffness at 5 % deflection.

8.5 *Hoop-Tensile Strength*—Determine the hoop-tensile strength by Test Method D 2290, except that the sections on Apparatus and Test Specimens may be modified to suit the size of specimens to be tested, and the maximum load rate may not exceed 0.10 in/min. Alternatively, Test Method D 638 may be employed. Specimen width may be increased for pipe wall thicknesses greater than 0.55 in. (14 mm). Means may be provided to minimize the bending moment imposed during the test. Cut three specimens from the test sample. Record the load to fail each specimen and determine the specimen width as close to the break as possible. Use the measured width and failure load to calculate the hoop-tensile strength.

8.5.1 *Alternative Minimum Hoop-Tensile Strength Requirement*—As an alternative, the minimum hoop-tensile strength values may be determined as follows:

$$F = (S_i/S_r)(Pr) \quad (2)$$

where:

F = required minimum hoop tensile strength, lbf/in.,
S_i = initial design hoop tensile stress, psi,
S_r = hoop tensile stress at rated operating pressure, psi,
P = rated operating pressure class, psi, and
r = inside radius of pipe, in.

NOTE 13—A value of F less than 4 Pr results in a lower factor of safety on short term loading than required by the values in Table 8.

The value for S_i should be established by considering the variations in glass reinforcement strength and manufacturing methods, but in any case should not be less than the 95 % lower confidence value on stress at 0.1 h, as determined by the manufacturer's testing carried out in accordance with 6.4. The value for S_r should be established from the manufacturer's hydrostatic design basis.

8.6 *Longitudinal Strength*:

8.6.1 *Beam Strength*—Place a 20-ft (6.1-m) nominal length of pipe on saddles at each end. Hold the ends of the pipe round during the test. Apply beam load for the diameter of pipe shown in Table 9 simultaneously to the pipe through two saddles located at the third points of the pipe (see Fig. 2). The loads shall be maintained for not less than 10 min with no evidence of failure. The testing apparatus shall be designed to minimize stress concentrations at the loading points.

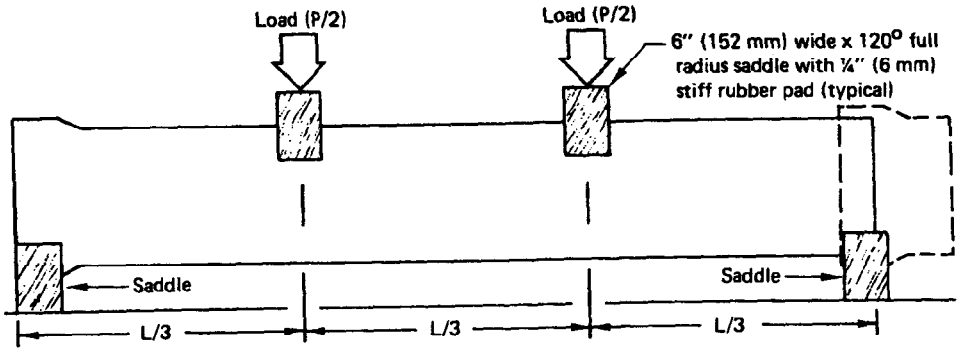

FIG. 2 Beam Strength—Test Setup

8.6.2 *Longitudinal Tensile Strength*—Determine in accordance with Test Method D 638, except the provision for maximum thickness shall not apply.

8.6.3 *Longitudinal Compressive Strength*—Determine in accordance with Test Method D 695.

9. Packaging and Package Marking

9.1 Mark each length of pipe that meets or is part of a lot that meets the requirements of this specification at least once in letters not less than ½ in. (12 mm) in height and of bold-type style in a color and type that remains legible under normal handling and installation procedures. The marking shall include the nominal pipe size, manufacturer's name or trademark, this ASTM specification number: D 3517, type, liner, grade, class, and stiffness in accordance with the designation code in 4.2.

9.2 Prepare pipe for commercial shipment in such a way as to ensure acceptance by common or other carriers.

9.3 All packing, packaging, and marking provisions of Practice D 3892 shall apply to this specification.

ANNEX

(Mandatory Information)

A1. ALTERNATIVE HYDROSTATIC DESIGN METHOD

A1.1 The following symbols are used:

S = tensile stress in the glass fiber reinforcement in the hoop orientation corrected for the helix angle, psi,
P = internal pressure, psig,
P_1 = long-term hydrostatic pressure, psig,
D = nominal inside pipe diameter, in.,
t_h = actual cross-sectional area of glass-fiber reinforcement applied around the circumference of the pipe, $in.^2/in.$,
θ = plane angle between hoop-oriented reinforcement and longitudinal axis of the pipe (helix angle), and
HDB = hydrostatic-design basis, psi.

A1.2 The hydrostatic design is based on the estimated tensile stress of the reinforcement in the wall of the pipe in the circumferential (hoop) orientation that will cause failure after 50 years of continuously applied pressure as described in Procedure B of Practice D 2992. Strength requirements are calculated using the strength of hoop-oriented glass reinforcement only, corrected for the helix angle of the fibers.

A1.3 *Hoop-Stress Calculation* is derived from the ISO equation for hoop stress, as follows:

$$S = PD/2(t_h \sin \theta)$$

This stress is used as the ordinate (long-term strength) in calculating the regression line and lower confidence limit in accordance with Annexes A1 and A3 of Practice D 2992.

NOTE A1.1—The calculated result for S may be multiplied by the factor 6.895 to convert from psi to kPa.

A1.4 *Hydrostatic-Design Basis*—The value of S is determined by extrapolation of the regression line to or 50 years in accordance with Practice D 2992.

A1.5 *Hydrostatic-Design Basis Categories*—Convert the value of the HDB to internal hydrostatic pressure in psig as follows:

$$P_1 = 2(t_h \sin \theta)(\text{HDB})/D$$

The pipe is categorized in accordance with Table A1.1.

NOTE A1.2—The calculated result P_1 may be multiplied by the factor 6.895 to convert from psig to kPa.

A1.6 *Pressure Class Rating*—The classes shown in Table A1.1 are based on the intended working pressure in psig for commonly encountered conditions of water service. The purchaser should determine the class of pipe most suitable to the installation and operating conditions that will exist on the

TABLE A1.1 Long-Term Hydrostatic Pressure Categories

Class	Minimum Calculated Values of Long-Term Hydrostatic Pressure, P_1 gage, psi (kPa)
C50	90 (621)
C75	185 (931)
C100	180 (1241)
C125	225 (1551)
C150	270 (1862)
C175	315 (2172)
C200	360 (2482)
C225	405 (2792)
C250	450 (3103)

project on which the pipe is to be used by multiplying the values of P_1 from Table A1.1 by a service (design) factor selected for the application on the basis of two general groups of conditions. The first group considers the manufacturing and testing variables, specifically normal variations in the material, manufacture, dimensions, good handling techniques, and in the evaluation procedures in this method. The second group considers the application or use, specifically installation, environment, temperature, hazard involved, life expectancy desired, and the degree of reliability selected.

NOTE A1.3—It is not the intent of this standard to give service (design) factors. The service (design) factor should be selected by the design engineer after evaluating fully the service conditions and the engineering properties of the specific plastic pipe material under consideration. Recommended service (design) factors will not be developed or issued by ASTM.

APPENDIXES

(Nonmandatory Information)

X1. INSTALLATION

X1.1 These specifications are material performance and purchase specifications only and do not include requirements for engineering design, pressure surges, bedding, backfill or the relationship between earth cover load, and the strength of the pipe. However, experience has shown that successful performance of this product depends upon the proper type of bedding and backfill, pipe characteristics, and care in the field construction work. The purchaser of the fiberglass pressure pipe specified herein is cautioned that he must properly correlate the field requirements with the pipe requirements and provide adequate inspection at the job site.

X2. RECOMMENDED METHODS FOR DETERMINING GLASS CONTENT

X2.1 Determine glass content as follows:

X2.1.1 By ignition loss analysis in accordance with Test Method D 2584 or ISO 1172.

X2.1.2 As a process control, by weight of the glass fiber reinforcement applied by machine into the pipe structure.

SUMMARY OF CHANGES

Committee D20 has identified the location of selected changes to this standard since the last issue, D 3517–96, that may impact this standard.

(*1*) Changed acronym, RPMP, definition from reinforced *plastic* mortar pipe to reinforced *polymer* mortar pipe.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: D 3754 – 01

Standard Specification for "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Sewer and Industrial Pressure Pipe[1]

This standard is issued under the fixed designation D 3754; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope *

1.1 This specification covers machine-made fiberglass pipe, 8 in. (200 mm) through 144 in. (3700 mm), for use in pressure systems for conveying sanitary sewage, storm water, and many industrial wastes, and corrosive fluids. Both glass-fiber-reinforced thermosetting-resin pipe (RTRP) and glass-fiber-reinforced polymer mortar pipe (RPMP) are fiberglass pipes. This standard is suited primarily for pipes to be installed in buried applications, although it may be used to the extent applicable for other installations such as, but not limited to, sliplining and rehabilitation of existing pipelines. Pipe covered by this specification is intended to operate at internal gage pressures of 250 psi (1.72 MPa) or less.

NOTE 1—For the purposes of this standard, polymer does not include natural polymers.

1.2 The values given in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

NOTE 2—There is no similar or equivalent ISO standard.

1.3 The following precautionary caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

AWWA C-950 Glass-Fiber Reinforced Thermosetting Resin Pressure Pipe[9]

3. Terminology

3.1 *Definitions:*

3.1.1 *General*—Definitions are in accordance with Terminology D 883 or Terminology F 412 and abbreviations with Terminology D 1600, unless otherwise indicated.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *fiberglass pipe*—a tubular product containing glass fiber reinforcements embedded in or surrounded by cured thermosetting resin. The composite structure may contain aggregate, granular or platelet fillers, thixotropic agents, pigments, or dyes. Thermoplastic or thermosetting liners or coatings may be included.

3.2.2 *reinforced thermosetting resin pipe*—a fiberglass pipe without aggregate.

3.2.3 *reinforced polymer mortar pipe*—a fiberglass pipe with aggregate.

3.2.4 *industrial pipe*—pipe designed for internal, or external environments, or both, commonly encountered in industrial piping systems used for many process solutions or effluents.

3.2.5 *qualification test*—one or more tests used to prove the design of a product. Not a routine quality control test.

3.2.6 *liner*—a resin layer, with or without filler or reinforcement, or both, forming the interior surface of the pipe.

3.2.7 *surface layer*—a resin layer, with or without filler or reinforcement, or both, applied to the exterior surface of the pipe structural wall.

4. Classification

4.1 *General*—This specification covers fiberglass sewer and industrial pressure pipe defined by raw materials in the structural wall (type) and liner, surface layer material (grade), operating pressure (class), and pipe stiffness. Table 1 lists the types, liners, grades, classes, and stiffnesses that are covered.

NOTE 3—All possible combinations of types, liners, grades, classes, and stiffness may not be commercially available. Additional types, liners, grades, and stiffnesses may be added as they become commercially available. The purchaser should determine for himself or consult with the manufacturer for the proper class, type, liner, grade, and stiffness of pipe to be used under the installation and operating conditions that will exist for the project in which the pipe is to be used.

4.2 *Designation Requirements*—The pipe materials designation code shall consist of the standard designation, ASTM D 3754, followed by type, liner, and grade in arabic numerals, class by the letter C with two or three arabic numerals, and pipe stiffness by a capital letter. Table 1 presents a summary of the designation requirements. Thus a complete material code shall consist of ASTM D 3754, three numerals, C...and two or three numerals, and a capital letter.

NOTE 4—Examples of the designation codes are as follows: (*1*) ASTM D 3754-1-1-3-C50-A for glass-fiber-reinforced aggregate and polyester resin mortar pipe with a reinforced thermoset liner and an unreinforced polyester resin and sand surface layer, for operation at 50 psi (345 kPa), and having a minimum pipe stiffness of 9 psi (62 kPa). (*2*) ASTM D 3754-4-2-6-C200-C for glass-fiber-reinforced epoxy resin pipe with an unreinforced thermoset liner, no surface layer, for operation at 200 psi (1380 kPa) and having a minimum pipe stiffness of 36 psi (248 kPa).

NOTE 5—Although the "Form and Style for ASTM Standards" manual requires that the type classification be roman numerals, it is recognized that few companies have stencil-cutting equipment for this style of type, and it is therefore acceptable to mark the product type in arabic numbers.

5. Materials and Manufacture

5.1 *General*—The resins, reinforcements, colorants, fillers, and other materials, when combined as a composite structure, shall produce a pipe that shall meet the performance requirements of this specification.

5.2 *Wall Composition*—The basic structural wall composition shall consist of a thermosetting resin, glass-fiber reinforcement, and, if used, an aggregate filler.

[9] Available from the American Water Works Association, 6666 West Quincey Ave., Denver, CO 80235.

TABLE 1 General Designation Requirements for Fiberglass Pressure Pipe

Designation	Property	Cell Limits[A]								
1	Type	1 glass-fiber-reinforced thermosetting polyester[B] resin mortar (RPMP polyester)[B]		2 glass-fiber-reinforced thermosetting polyester[B] resin (RTRP polyester)[B]		3 glass-fiber-reinforced thermosetting epoxy resin mortar (RPMP epoxy)		4 glass-fiber-reinforced thermosetting epoxy resin (RTRP epoxy)	
2	Liner	1 reinforced thermoset liner		2 non-reinforced thermoset liner		3 thermoplastic liner		4 no liner	
3	Grade	1 Polyester resin surface layer—reinforced[B]	2 polyester[B] resin surface layer—nonreinforced[B]	3 polyester[B] resin and sand surface layer nonreinforced		4 epoxy resin surface layer—reinforced		5 epoxy resin surface layer—nonreinforced	6 No surface layer
4	Class[C]	C50	C75	C100	C125	C150	C175	C200	C225	C250
5	Pipe Stiffness psi (kPa)	A 9 (62)		B 18 (124)		C 36 (248)		D 72 (496)[ABC]		

[A] The cell-type format provides the means of identification and specification of piping materials. This cell-type format, however, is subject to misapplication since unobtainable property combinations can be selected if the user is not familiar with commercially available products. The manufacturer should be consulted.

[B] For the purposes of this standard, polyester includes vinyl ester resin.

[C] Based on operating pressure in psig (numerals).

Copyright by the ASTM International
Wed Feb 02 01:59:43 2005

5.2.1 *Resin*—A thermosetting polyester or epoxy resin, with or without filler.

5.2.2 *Aggregate*—A siliceous sand conforming to the requirements of Specification C 33, except that the requirements for gradation shall not apply.

5.2.3 *Reinforcement*—A commercial grade of glass fiber with a sizing compatible with the resin used.

5.3 *Liner and Surface Layers*—A liner or surface layer, or both, when incorporated into or onto the pipe shall meet the chemical and structural requirements of this specification.

5.4 *Joints*—The pipe shall have a joining system that shall provide for fluid tightness for the intended service condition.

5.4.1 *Unrestrained*—Pipe joints capable of withstanding internal pressure but not longitudinal forces.

5.4.1.1 *Coupling or Bell-and-Spigot Gasket Joints*, with a groove either on the spigot or in the bell to retain an elastomeric gasket that shall be the sole element of the joint to provide watertightness. For typical joint detail see Fig. 1.

5.4.1.2 *Mechanical Couplings*.

5.4.2 *Restrained*—Pipe joints capable of withstanding internal pressure and longitudinal forces.

5.4.2.1 Joints similar to those in 5.4.1.1 with supplemental restraining elements.

5.4.2.2 *Butt Joint*, with laminated overlay.

5.4.2.3 *Bell-and-Spigot*, with laminated overlay.

5.4.2.4 *Bell-and-Spigot*, adhesive bonded.

5.4.2.5 *Flanged*.

5.4.2.6 *Mechanical*.

NOTE 6—Other types of joints may be added as they become commercially available.

5.5 *Gaskets*—Elastomeric gaskets, when used with this pipe, shall conform to the requirements of Specification F 477, except that composition of the elastomer shall be as agreed upon between the purchaser and the supplier for the particular exposure to oily or aggressive-chemical environments.

6. Requirements

6.1 *Workmanship*:

6.1.1 Each pipe shall be free from all defects including indentations, delaminations, bubbles, pinholes, cracks, pits, blisters, foreign inclusions, and resin-starved areas that due to their nature, degree, or extent, detrimentally affect the strength and serviceability of the pipe. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

6.1.2 The inside surface of each pipe shall be free of bulges, dents, ridges, or other defects that result in a variation of inside diameter of more than ⅛ in. (3.2 mm) from that obtained on adjacent unaffected portions of the surface. No glass-fiber reinforcement shall penetrate the interior surface of the pipe wall.

6.1.3 Joint sealing surfaces shall be free of dents, gouges, or other surface irregularities that will affect the integrity of the joints.

6.2 *Dimensions*:

6.2.1 *Pipe Diameters*—The pipe shall be supplied in the nominal diameters shown in Table 2 or Table 3. The pipe diameter tolerances shall be as shown in Table 2 or Table 3, when measured in accordance with 8.1.1.

6.2.2 *Lengths*—The pipe shall be supplied in nominal lengths of 10, 20, 30, 40, and 60 ft (3.05, 6.10, 9.15, 12.19, and 18.29 m). The actual laying length shall be the nominal length ±2 in. (±51 mm), when measured in accordance with 8.1.2. At least 90 % of the total footage of any one size and class, excluding special-order lengths, shall be furnished in the nominal lengths specified by the purchaser. Random lengths, if furnished, shall not vary from the nominal lengths by more than 5 ft (1.53 m), or 25 %, whichever is less.

6.2.3 *Wall Thickness*—The average wall thickness of the pipe shall not be less than the nominal wall thickness published in the manufacturer's literature current at the time of purchase, and the minimum wall thickness at any point shall not be less than 87.5 % of the nominal wall thickness when measured in accordance with 8.1.3.

6.2.4 *Squareness of Pipe Ends*—All points around each end of a pipe unit shall fall within ±¼in. (6.4 mm) or ±0.5 % of the nominal diameter of the pipe, whichever is greater, to a plane perpendicular to the longitudinal axis of the pipe, when measured in accordance with 8.1.4.

6.3 *Chemical Requirements*:

6.3.1 *Sanitary Sewer Service* :

6.3.1.1 *Long-Term*—Pipe specimens, when tested in accordance with 8.2.1 shall be capable of being deflected, without failure, at the 50 year strain level given in Table 4 when exposed to 1.0 *N* sulfuric acid.

NOTE 7—See Appendix X1 for derivation of the minimum sanitary sewer pipe chemical requirements given in Table 4.

6.3.1.2 *Control Requirements*—Test pipe specimens periodically in accordance with 8.2.1.3, following the procedure of 8.2.1.4, or alternatively, the procedure of 8.2.1.5.

6.3.1.3 When the procedure of 8.2.1.4 is used, the following three criteria must be met: a) the average failure time at each strain level must fall at or above the lower 95 % confidence limit of the originally determined regression line, b) no specimen-failure times may be sooner than the lower 95 % prediction limit of the originally determined regression line, and c) one-third or more of the specimen failure times must be on or above the originally determined regression line.

NOTE 8—Determine the lower 95 % confidence limit and the lower 95 % prediction limit in accordance with to Annex A2.

6.3.1.4 When the alternative method of 8.2.1.5 is used, failure shall not occur in any specimen.

6.3.2 *Industrial Service*—The resin component of the liner or of the surface layer, or both, shall be a commercial-grade corrosion-resistant thermoset that has either been evaluated in a laminate by test, in accordance with 8.2.2, or that has been determined by previous documented service to be acceptable

114	±1.00	...	...	...	...
120	±1.00	...	...	...	...
132	±1.00	...	...	...	...
144	±1.00	...	...	...	...

[A] Inside diameters other than those shown shall be permitted by agreement between purchaser and supplier.
[B] Values are taken from International Standards Organization documents. Parentheses indicate non-preferred diameters.

for the service conditions. Where service conditions have not been evaluated, a suitable resin may also be selected by agreement between the manufacturer and purchaser.

NOTE 9—The results obtained by this test shall serve as a guide only in the selection of a pipe material for a specific service application. The purchaser is cautioned to evaluate all of the various factors that may enter into the serviceability of a pipe material when subjected to chemical environment, including chemical resistance in the strained condition.

6.4 *Soundness*—Unless otherwise agreed upon between purchaser and supplier, test each length of pipe up to 54 in. (1370 mm) diameter hydrostatically without leakage or cracking, at the internal hydrostatic proof pressures specified for the applicable class in Table 5 when tested in accordance with 8.3. For sizes over 54 in., the frequency of hydrostatic leak tests shall be as agreed upon by purchaser and supplier.

6.5 *Hydrostatic Design Basis*:

6.5.1 *Long-Term Hydrostatic Pressure*—The pressure classes shall be based on long-term hydrostatic pressure data obtained in accordance with 8.4 and categorized in accordance with Table 6. Pressure classes are based on extrapolated strengths at 50 years. For pipe subjected to longitudinal loads or circumferential bending, the effect of these conditions on the hydrostatic design pressure classification of the pipe must be considered.

6.5.2 *Control Requirements*—Test pipe specimens periodically in accordance with the reconfirmation procedures described in Practice D 2992.

NOTE 10—Hydrostatic design basis (HDB—extrapolated value at 50 years) determined in accordance with Procedure A of Practice D 2992, may be substituted for the Procedure B evaluation required by 8.4. It is generally accepted that the Procedure A value multiplied by 3 is equivalent to the Procedure B value.

6.6 *Stiffness*—Each length of pipe shall have sufficient strength to exhibit the minimum pipe stiffness ($F/\Delta y$) specified in Table 7 when tested in accordance with 8.5. At deflection level A per Table 8, there shall be no visible damage in the test specimen evidenced by surface cracks. At deflection level B per Table 8, there shall be no indication of structural damage as evidenced by interlaminar separation, separation of the liner or surface layer (if incorporated) from the structural wall, tensile failure of the glass-fiber reinforcement, fracture, or buckling of the pipe wall.

NOTE 11—This is a visual observation (made with the unaided eye) for quality control purposes only, and should not be considered a simulated service test. Table 8 values are based on an in-use long-term deflection limit of 5 % and provide an appropriate uniform safety margin for all pipe stiffnesses. Since the pipe-stiffness values ($F/\Delta y$) shown in Table 7 vary, the percent deflection of the pipe under a given set of installation conditions will not be constant for all pipes. To avoid possible misapplication, take care to analyze all conditions that might affect performance of the installed pipe.

6.6.1 For other pipe stiffness levels, appropriate values for Level A and Level B deflections (Table 8) may be computed as follows:

TABLE 4 Minimum Sanitary Sewer Pipe Chemical Requirements

ϵ_{scv}

Pipe Stiffness, psi (kPa)	Minimum Strain					
	6 min	10 h	100 h	1 000	10 000	50 years
9 (62)	0.97 (*t/de*)	0.84 (*t/d*)	0.78 (*t/d*)	0.73 (*t/d*)	0.68 (*t/d*)	0.60 (*t/d*)
18 (124)	0.85 (*t/d*)	0.72 (*t/d*)	0.66 (*t/d*)	0.61 (*t/d*)	0.56 (*t/d*)	0.49 (*t/d*)
36 (248)	0.71 (*t/d*)	0.60 (*t/d*)	0.55 (*t/d*)	0.51 (*t/d*)	0.47 (*t/d*)	0.41 (*t/d*)
72 (496)	0.56 (*t/d*)	0.48 (*t/d*)	0.44 (*t/d*)	0.41 (*t/d*)	0.38 (*t/d*)	0.34 (*t/d*)

Where: *t* and *d* are the nominal total wall thickness and the mean diameter (inside diameter plus *t*) as determined in accordance with 8.1.

$$\text{Level A at new PS} = \left(\frac{72}{\text{new PS}}\right)^{0.33} (9) \quad (1)$$

$$\text{Level B at new PS} = \text{new Level A} \div 0.6$$

6.6.2 Since products may have use limits of other than 5 % long-term deflection, Level A and Level B deflections (Table 8) may be proportionally adjusted to maintain equivalent in-use safety margins. For example, a 4 % long-term limiting deflection would result in a 20 % reduction of Level A and Level B

deflections, while a 6 % limiting deflection would result in a 20 % increase in Level A and Level B deflection values. However, minimum values for Level A and Level B deflections shall be equivalent to strains of 0.6 and 1.0 % respectively (as computed by Eq X1.1 in Appendix X1).

6.7 *Hoop-Tensile Strength*—All pipe manufactured under this specification shall meet or exceed the hoop-tensile strength shown for each size and class in Table 9 and Table 10, when tested in accordance with 8.6.

6.7.1 *Alternative Requirements*—When agreed upon by the purchaser and the supplier, the minimum hoop tensile strength shall be as determined in accordance with 8.6.1.

6:8 *Joint Tightness*—The pipe joint shall meet the performance requirements of the applicable section of Specification D 4161. Restrained rigid joints (5.4.2.2, 5.4.2.3, 5.4.2.4, and 5.4.2.5) shall be exempt from angular deflection requirements.

6.9 *Longitudinal Strength:* :

6.9.1 *Beam Strength*—For pipe sizes up to 27 in. (686 mm), the pipe shall withstand, without failure, the beam loads specified in Table 11, when tested in accordance with 8.7.1. For pipe sizes larger than 27 in., and alternatively for smaller sizes, adequate beam strength is demonstrated by tensile and compression tests conducted in accordance with 8.7.2 and 8.7.3 respectively, for pipe wall specimens oriented in the longitudinal direction, using the minimum tensile and compression strengths specified in Table 11.

6.9.2 *Longitudinal Tensile Strength*—All pipe manufactured under this specification shall meet or exceed the longitudinal tensile strength shown for each size and class in Table 12 and

TABLE 9 Minimum Hoop Tensile Strength of Pipe Wall Inch-Pound Units

Nominal Diameter in.	Hoop Tensile Strength, lbf/in. Width

Table 13, when tested in accordance with 8.7.2.

NOTE 12—The values listed in Table 12 are the minimum criteria for products made to this standard. The values may not be indicative of the axial strength of some products, or of the axial strength required by some installation conditions and joint configurations.

6.9.3 Conformance to the requirements of 6.9.1 shall satisfy the requirements of 6.9.2 for those pipe sizes and classes where the minimum longitudinal tensile strength values of Table 11 are equal to the values of Table 12. Conformance to the requirements of 6.9.2 shall satisfy the longitudinal tensile strength requirements of 6.9.1.

7. Sampling

7.1 *Lot*—Unless otherwise agreed upon by the purchaser and the supplier, one lot shall consist of 100 lengths of each type, grade, and size of pipe produced.

7.2 *Production Tests*—Select one pipe at random from each lot and take one specimen from the pipe barrel to determine conformance of the material to the workmanship, dimensional, and strength requirements of 6.1, 6.2, 6.6, and 6.7 respectively. Unless otherwise agreed upon between purchaser and supplier, all pipes (up to 54 in. diameter) shall meet the soundness requirements of 6.4.

7.3 *Qualification Tests*—Sampling for qualification tests is not required unless otherwise agreed upon by the purchaser and the supplier. Qualification tests, for which a certification and test report shall be furnished when requested by the purchaser, include the following:

7.3.1 Sanitary sewer service, long-term chemical test.

7.3.2 Industrial service resin component chemical test. A copy of the resin manufacturer's test report may be used as the basis of acceptance for this test as agreed upon by the purchaser and the supplier.

7.3.3 Long-term hydrostatic pressure test.

7.3.4 Joint-tightness test, see 6.8.

7.3.5 Longitudinal strength test, including:

7.3.5.1 Beam strength, and

7.3.5.2 Longitudinal tensile strength.

7.4 *Control Tests*—The following tests are considered control requirements and shall be performed as agreed upon between the purchaser and the supplier.

7.4.1 *Soundness Test*—60 in. (1524 mm) diameter pipe and larger

7.4.2 Perform sampling and testing for the control requirements for sanitary sewer service at least once annually.

7.4.3 Perform sampling and testing for the control requirements for hydrostatic design basis at least once every two years.

7.5 For individual orders, conduct only those additional tests and number of tests specifically agreed upon between purchaser and supplier.

8. Test Methods

8.1 *Dimensions*:

8.1.1 *Diameters*:

8.1.1.1 *Inside Diameter*—Take inside diameter measurements at a point approximately 6 in. (152 mm) from the end of the pipe section using a steel tape or an inside micrometer with

graduations of 1/16 in. (1 mm) or less. Take two 90° opposing measurements at each point of measurement and average the readings.

8.1.1.2 *Outside Diameter*—Determine in accordance with Test Method D 3567.

8.1.2 *Length*—Measure with a steel tape or gage having graduations of 1/16in. (1 mm) or less. Lay the tape or gage on or inside the pipe and measure the overall laying length of the pipe.

8.1.3 *Wall Thickness*—Determine in accordance with Test Method D 3567.

8.1.4 *Squareness of Pipe Ends*—Rotate the pipe on a mandrel or trunions and measure the runout of the ends with a dial indicator. The total indicated reading is equal to twice the distance from a plane perpendicular to the longitudinal axis of the pipe. Alternatively, when the squareness of the pipe ends is rigidly fixed by tooling, the tooling may be verified and reinspected at intervals frequent enough to assure that the squareness of the pipe ends is maintained within tolerance.

8.2 *Chemical Tests*:

8.2.1 *Sanitary-Sewer Service*—Test the pipe in accordance with Test Method D 3681.

8.2.1.1 *Long-Term*—To find if the pipe meets the requirements of 6.3.1, determine at least 18 failure points in accordance with Test Method D 3681.

8.2.1.2 *Alternative Qualification Procedure*—Test four specimens each at the 10 and 10 000 h minimum strains given in Table 4 and test five specimens each at the 100 and 1000 h minimum strains given in Table 4. Consider the product qualified if all 18 specimens are tested without failure for at least the prescribed times given in Table 4 (that is, 10, 100, 1000 or 10 000 h respectively).

8.2.1.3 *Control Requirements*—Test at least six specimens in accordance with one of the following procedures and record the results.

8.2.1.4 Test at least 3 specimens at each of the strain levels corresponding to the 100- and 1000-h failure times from the product's regression line established in 8.2.1.

8.2.1.5 When the alternative method described in 8.2.1.2 is used to qualify the product, test at least three specimens each at the 100 and 1000 h minimum strains given in Table 4 for at least 100 and 1000 h respectively.

8.2.1.6 The control test procedures of 8.2.1.5 may be used as an alternative procedure to the reconfirmation procedure described in Test Method D 3681 for those products evaluated by the alternative qualification procedure described in 8.2.1.2.

8.2.2 *Industrial Service*—The resin component of the liner or of the surface layer, or both, to be subjected to an aggressive service environment, shall be tested in accordance with Test Method C 581, except that the specimens tested shall be representative of the laminate construction used in the liner or surface layer, or both.

8.3 *Soundness*—Determine soundness by a hydrostatic proof test procedure. Place the pipe in a hydrostatic pressure

testing machine that seals the ends and exerts no end loads. Fill the pipe with water, expelling all air, and apply internal water pressure at a uniform rate not to exceed 50 psi (345 kPa)/s until the test pressure shown in Table 5 for the applicable class is reached. Maintain this pressure for a minimum of 30 s. The pipe shall show no visual signs of weeping, leakage, or fracture of the structural wall.

8.4 *Long-Term Hydrostatic Pressure*—Determine the long-term hydrostatic pressure at 50 years in accordance with Procedure B of Practice D 2992, with the following exceptions permitted:

8.4.1 Test at ambient temperatures within the limits of 50°F (10°C) and 110°F (43.5°C) and report the temperature range experienced during the tests.

NOTE 13—Tests indicate no significant effects on long-term hydrostatic pressure within the ambient temperature range specified.

8.4.2 Determine the hydrostatic design basis for the glass-fiber reinforcement in accordance with the method in Annex A1.

8.4.3 Calculate the long-term hydrostatic pressure and categorize by class in accordance with Table 6. Annex A1.6 explains how to calculate the long-term hydrostatic pressure.

8.5 *Stiffness*—Determine the pipe stiffness ($F/\Delta y$) at 5 % deflection for the specimen, using the apparatus and procedure of Test Method D 2412, with the following exceptions permitted:

8.5.1 Measure the wall thickness to the nearest 0.01 in. (0.25 mm).

8.5.2 Load the specimen to 5 % deflection and record the load. Then load the specimen to deflection level A per Table 8 and examine the specimen for visible damage evidenced by surface cracks. Then load the specimen to deflection level B per Table 8 and examine for evidence of structural damage, as evidenced by interlaminar separation, separation of the liner or surface layer (if incorporated) from the structural wall, tensile failure of the glass-fiber reinforcement, fracture, or buckling of the pipe wall. Calculate the pipe stiffness at 5 % deflection.

8.5.3 For production testing, only one specimen need be tested to determine the pipe stiffness.

8.5.4 The maximum specimen length may be 12 in. (305 mm), or the length necessary to include stiffening ribs if they are used, whichever is greater.

NOTE 14—As an alternative to determining pipe stiffness using the apparatus and procedure of Test Method D 2412, the supplier may submit to the purchaser for approval a test method and test evaluation based on Test Method D 790 accounting for the substitution of curved test specimens and measurement of stiffness at 5 % deflection.

8.6 *Hoop-Tensile Strength*—Determine hoop tensile strength by Test Method D 2290, except that the sections on apparatus and test specimens may be modified to suit the size of the specimens to be tested, and the maximum load rate may not exceed 0.10 in./min (2.54 mm/min). Alternatively, Test

144	480	511	681	851	1 021	1 021	1 123	1 264	1 404

Method D 638 may be employed. Specimen width may be increased for pipe wall thickness greater than 0.55 in (13.97 mm). Means may be provided to minimize the bending moment imposed during the test. Three specimens shall be cut from the test sample. Record the load to fail each specimen and determine the specimen width as close to the break as possible. Use the measured width and failure load to calculate the hoop-tensile strength.

8.6.1 *Alternative Minimum Hoop-Tensile Strength Requirement*—As an alternative, the minimum hoop-tensile strength values may be determined through the use of the following formula:

$$F = (S_i/S_r)\,(P_r) \qquad (2)$$

where:

F = required minimum hoop-tensile strength, lbf/in.,
S_i = initial design hoop tensile stress, psi,
S_r = hoop tensile stress at rated operating pressure, psi,
P = rated operating pressure class, psi, and
r = inside radius of pipe, in.

The value for S_i should be established by considering the variations in glass reinforcement strength and manufacturing methods, but in any case, should not be less than the 95 % lower confidence value on stress at 0.1 h, as determined by the manufacturer's testing carried out in accordance with 6.5. The value for S_r should be established from the manufacturer's hydrostatic design basis.

NOTE 15—A value of F less than 4 Pr results in a lower factor of safety on short term loading than required by the values in Table 9.

8.7 *Longitudinal Strength* :

8.7.1 *Beam Strength*—Place a 20-ft (6.1-m) nominal length of pipe on saddles at each end. Hold the ends of the pipe round during the test. Apply the beam load for the diameter of pipe shown in Table 11 simultaneously to the pipe through two saddles located at the third points of the pipe (see Fig. 2). Maintain the loads for not less than 10 min with no evidence of failure. The testing apparatus shall be designed to minimize stress concentrations at the loading points.

8.7.2 *Longitudinal Tensile Strength*—Determine in accordance with Test Method D 638, except the provisions for maximum thickness shall not apply.

8.7.3 *Longitudinal Compressive Strength*—Determine in accordance with Test Method D 695.

9. Packaging, Marking, and Shipping

9.1 Mark each length of pipe that meets or is part of a lot that meets the requirements of this specification at least once, in letters not less than ½ in. (12 mm) in height and of bold-type style in a color and type that remains legible under normal handling and installation procedures. Include in the marking the nominal pipe size, manufacturer's name or trademark, ASTM Specification number D 3754, type, liner, grade, class, and stiffness in accordance with the designation code in 4.2.

9.2 Prepare pipe for commercial shipment in such a way as

Copyright by the ASTM International
Wed Feb 02 01:59:45 2005

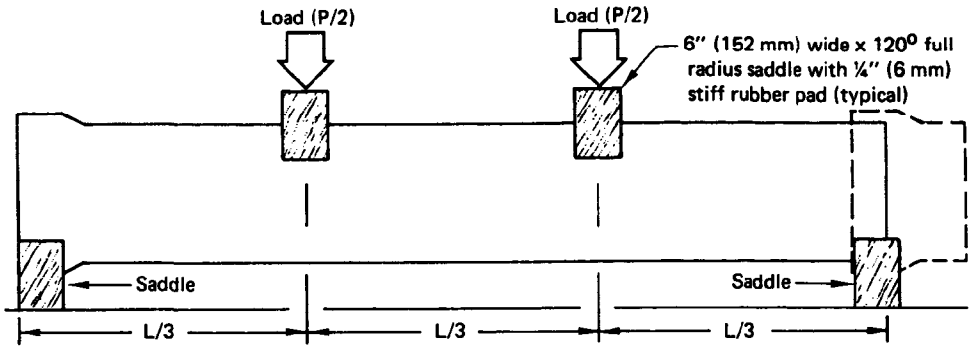

FIG. 2 Beam Strength-Test Setup

to ensure acceptance by common or other carriers.

9.3 All packing, packaging, and marking provisions of Practice D 3892 shall apply to this specification.

ANNEXES

(Mandatory Information)

A1. ALTERNATIVE HYDROSTATIC DESIGN METHOD

A1.1 The following symbols are used:

S = tensile stress in the glass-fiber reinforcement in the hoop orientation corrected for the helix angle, psi,

P = internal pressure, psig,

P_l = long-term hydrostatic pressure, psig,

D = nominal inside pipe diameter, in.,

t_h = actual cross-sectional area of glass-fiber reinforcement applied around the circumference of the pipe, $in.^2/in.$,

θ = plane angle between hoop-oriented reinforcement and longitudinal axis of the pipe (helix angle), and

HDB = hydrostatic design basis, psi.

A1.2 The hydrostatic design is based on the estimated tensile stress of reinforcement in the wall of the pipe in the circumferential (hoop) orientation that will cause failure after 50 years of continuously applied pressure, as described in 8.4 and Practice D 2992, Procedure B. Strength requirements are calculated using the strength of hoop-oriented glass reinforcements only, corrected for the helix angle of the fibers.

A1.3 *Hoop-Stress Calculation,* derived from the ISO formula for hoop stress, is as follows:

$$S = PD/2(t_h \sin \theta)$$

This stress is used as the ordinate (long-term strength) in calculating the regression line and lower confidence limit in accordance with Practice D 2992, Annexes A1 and A3.

NOTE A1.1—The calculated result for S may be multiplied by the factor 6.985 to convert from psi to kPa.

A1.4 *Hydrostatic Design Basis*—The value of S is determined by extrapolation of the regression line to 50 years in accordance with Practice D 2992.

A1.5 *Hydrostatic Design Basic Categories*—Convert the value of the HDB to internal hydrostatic pressure in psig as follows:

$$P_1 = 2\,(t_h \sin \theta)\,(\text{HDB})/D$$

The pipe is categorized in accordance with Table A1.1.

NOTE A1.2—The calculated result P_1 may be multiplied by the factor 6.895 to convert from psig to kPa.

A1.6 *Pressure Class Rating*—The classes shown in Table A1.1 are based on the intended working pressure in psig for commonly encountered conditions of water service. The purchaser should determine the class of pipe most suitable to the installation and operating conditions that will exist on the project on which the pipe is to be used by multiplying the values of P_1 from Table A1.1 by a service (design) factor selected for the application on the basis of two general groups of conditions. The first group considers the manufacturing and testing variables, specifically normal variations in the material, manufacture, dimensions, good handling techniques, and in the evaluation procedures in this method. The second group

TABLE A1.1 Long-Term Hydrostatic Pressure Categories

Class	Minimum Calculated Values of Long-Term Hydrostatic Pressure, P_1, gage, psi (kPa)
C50	90 (621)
C75	135 (931)
C100	180 (1241)
C125	225 (1551)
C150	270 (1862)
C175	315 (2172)
C200	360 (2482)
C225	405 (2792)
C250	450 (3103)

Wed Feb 02 01:59:45 2005

considers the application or use, specifically installation, environment, temperature, hazard involved, life expectancy desired, and the degree of reliability selected.

NOTE A1.3—It is not the intent of this standard to give service (design) factors. The service (design) factor should be selected by the design engineer after evaluating fully the service conditions and the engineering properties of the specific pipe material under consideration. Recommended service (design) factors will not be developed or issued by ASTM.

A2. CALCULATIONS OF LOWER CONFIDENCE (LCL) AND LOWER PREDICTION (LPL) LIMITS

$$h_{LCL} = (a + bf_o) - ts\sqrt{\frac{(f_o - F)^2}{U} + \frac{1}{N}}$$

$$h_{LPL} = (a + bf_o) - ts\sqrt{\frac{(f_o - F)^2}{U} + \frac{1}{N} + 1}$$

where all symbols are as defined in Annexes A1 and A3 of Practice D 2992 except:

f_o = log of stress (strain) level of interest

NOTE A2.1—Of the expected failures at stress (strain) f_o 97.5 % will occur after h_{LPL}. The average failure time at stress (strain) f_o will occur later than h_{LCL} 97.5 % of the time.

APPENDIXES

(Nonmandatory Information)

X1. STRAIN CORROSION PERFORMANCE REQUIREMENTS

X1.1 From Molin and Leonhardt, the expression for bending strain is given as: $\epsilon_b = D_f (t/d) (\delta v/d)$. With the common acceptance that these pipes must be capable of withstanding 5 % deflection long-term, the maximum installed bending strain may be expressed as:

$$\epsilon_b \text{ max} = (0.05) (D_f) (t/d)$$

Using the AWWA C-950 long-term bending factor of safety of 1.50, the minimum strain corrosion performance extrapolated to 50 years must be:

$$E_{scv} \geq (0.075) (D_f) (t/d)$$

X1.2 The shape factor, D_f, is dependent on both the pipe stiffness and the installation (for example, backfill material, backfill density, compaction method, haunching, trench configuration, native-soil characteristics and vertical loading). Assuming conservatively, installations achieved by tamped compaction with inconsistent haunching that will limit long-term deflections to 5 %, the following values of D_f *have been selected to be realistic, representative and limiting. Substituting these values in the above equation for* E_{SCV} yields the minimum required strain corrosion performances given below and in Table 4.

Pipe Stiffness (psi)	D_f	Minimum E_{SCV} Performance
9	8.0	0.60 (t/d)
18	6.5	0.49 (t/d)
36	5.5	0.41 (t/d)
72	4.5	0.34 (t/d)

NOTE X1.1—Products may have used limits of other than 5 % long-term deflection. In such cases, the requirements should be proportionally adjusted. For example, a 4 % long-term limiting deflection would result in a 50 year requirement of 80 % of Table 4, while a 6 % limiting deflection would yield a requirement of 120 % of Table 4.

X1.3 *Alternative Strain Corrosion Test Requirements:*

X1.3.1 At 0.1 h (6 min), the required strain corrosion performance is based on the level B deflections from Table 6 as follows:

$$\epsilon \text{ test} \geq Df\left[\frac{t}{Id + \delta V/2}\right]\left[\frac{\delta V}{d + \delta V/2}\right] \quad \text{(X1.1)}$$

or

$$\epsilon \text{ test} \geq Df\,(t/d)\,(\delta V/d)\left(\frac{1}{1 + \delta V/2d}\right)^2 \quad \text{(X1.2)}$$

Df for parallel plate loading is 4.28. Making the other substitutions yield:

Pipe Stiffness (psi)	Level B $\delta v / d$ (%)	Minimum Test
9	30	0.97 (t/d)
18	25	0.85 (t/d)
36	20	0.71 (t/d)
72	15	0.56 (t/d)

X1.3.2 The minimum strain values at 10, 100, 1000, and 10 000 h given in Table 4 are defined by a straight line connecting the points at 6 min and 50 years on a log-log plot.

X2. INSTALLATION

X2.1 This specification is a material performance and purchase specification only and does not include requirements for engineering design, pressure surges, bedding, backfill, or the relationship between earth cover load, and the strength of the pipe. However, experience has shown that successful performance of this product depends upon the proper type of bedding and backfill, pipe characteristics, and care in the field construction work. The purchaser of the fiberglass pressure pipe specified herein is cautioned that he must properly correlate the field requirements with the pipe requirements and provide adequate inspection at the job site.

X3. RECOMMENDED METHODS OF DETERMINING GLASS CONTENT

X3.1 Determine glass content as follows:

X3.1.1 By ignition loss analysis in accordance with Test Method D 2584 or ISO 1172.

X3.1.2 As a process control, by weight of the glass fiber reinforcement applied by machine into the pipe structure.

SUMMARY OF CHANGES

Committee D20 has identified the location of selected changes to this standard since the last issue, D 3754–96 that may impact the use of this standard.

(1) Changed acronym, RPMP, definition from reinforced *plastic* mortar pipe to reinforced *polymer* mortar pipe.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: D 4000 – 01

An American National Standard

Standard Classification System for Specifying Plastic Materials[1]

This standard is issued under the fixed designation D 4000; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope *

1.1 This standard provides a classification system for tabulating the properties of unfilled, filled, and reinforced plastic materials suitable for processing into parts.

NOTE 1—The classification system may serve many of the needs of industries using plastic materials. The standard is subject to revision as the need requires; therefore, the latest revision should always be used.

1.2 The classification system and subsequent line callout (specification) is intended to be a means of identifying plastic materials used in the fabrication of end items or parts. It is not intended for the selection of materials. Material selection should be made by those having expertise in the plastics field after careful consideration of the design and the performance required of the part, the environment to which it will be exposed, the fabrication process to be employed, the inherent properties of the material not covered in this document, and the economic factors.

1.3 This classification system is based on the premise that plastic materials can be arranged into broad generic families using basic properties to arrange the materials into groups, classes, and grades. A system is thus established which, together with values describing additional requirements, permits as complete a description as desired of the selected material.

1.4 In all cases where the provisions of this classification system would conflict with the referenced ASTM specification for a particular material, the latter shall take precedence.

NOTE 2—When using this classification system the two-letter, three-digit suffix system applies.

NOTE 3—When a material is used to fabricate a part where the requirements are too specific for a broad material callout, it is advisable for the user to consult the supplier to secure callout of the properties to suit the actual conditions to which the part is to be subjected.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 2843 Test Method for Density of Smoke from the Burning or Decomposition of Plastics[8]
D 2863 Test Method for Measuring the Minimum Oxygen Concentration to Support Candle-Like Combustion of Plastics (Oxygen Index)[8]
D 2951 Test Method for Resistance of Types III and IV Polyethylene Plastics to Thermal Stress-Cracking[8]
D 3012 Test Method for Thermal Oxidative Stability of Propylene Plastics, Using a Biaxial Rotator[8]
D 3029 Test Methods for Impact Resistance of Flat, Rigid Plastic Specimens by Means of a Tup (Falling Weight)[9]
D 3294 Specification for PTFE Resin Molded Sheet and Molded Basic Shapes[8]
D 3295 Specification for PTFE Tubing[8]
D 3296 Specification for FEP-Fluorocarbon Tube[8]
D 3350 Specification for Polyethylene Plastics Pipe and Fittings Materials[8]
D 3418 Test Method for Transition Temperatures of Polymers by Thermal Analysis[8]
D 3595 Specification for Polychlorotrifluoroethylene (PCTFE) Extruded Plastic Sheet and Film[8]
D 3638 Test Method for Comparative Tracking Index of Electrical Insulating Materials[10]
D 3713 Test Method for Measuring Response of Solid Plastics to Ignition by a Small Flame[11]
D 3801 Test Method for Measuring the Comparative Extinguishing Characteristics of Solid Plastics in a Vertical Position[8]
D 3892 Practice for Packaging/Packing of Plastics[8]
D 3895 Test Method for Oxidative-Induction Time of Polyolefins by Differential Scanning Calorimetry[8]
D 3915 Specification for Poly(Vinyl Chloride) (PVC) and Chlorinated Poly(Vinyl Chloride) (CPVC) Compounds for Plastic Pipe and Fittings Used in Pressure Applications[8]
D 3935 Specification for Polycarbonate (PC) Unfilled and Reinforced Material[8]

D 3965 Specification for Rigid Acrylonitrile-Butadiene-Styrene (ABS) Compounds for Pipe and Fittings[8]
D 3985 Test Method for Oxygen Gas Transmission Rate Through Plastic Film and Sheeting Using a Coulometric Sensor[6]
D 4020 Specification for Ultra-High-Molecular-Weight Polyethylene Molding and Extrusion Materials[8]
D 4066 Specification for Nylon Injection and Extrusion Materials[8]
D 4067 Specification for Reinforced and Filled Polyphenylene Sulfide Injection Molding and Extrusion Materials[8]
D 4101 Specification for Propylene Plastic Injection and Extrusion Materials[8]
D 4181 Specification for Acetal (POM) Molding and Extrusion Materials[8]
D 4203 Specification for Styrene-Acrylonitrile (SAN) Injection and Extrusion Materials[8]
D 4216 Specification for Rigid Poly(Vinyl Chloride (PVC) and Related Plastic Building Products Compounds[8]
D 4329 Practice for Operating Light and Water Apparatus (Fluorescent UV Condensation Type) for Exposure of Plastics[12]
D 4349 Specificaton for Polyphenylene Ether (PPE) Materials[12]
D 4364 Practice for Performing Accelerated Outdoor Weathering of Plastics Using Concentrated Natural Sunlight[12]
D 4396 Specification for Rigid Poly(Vinyl Chloride) (PVC) and Related Plastic Compounds for Nonpressure Piping Products[12]
D 4441 Specification for Aqueous Dispersions of Polytetrafluorethylene[12]
D 4474 Specification for Styrenic Thermoplastic Elastomer Injection Molding and Extrusion Materials (TES)[12]
D 4507 Specification for Thermoplastic Polyester (TPES) Materials[13]
D 4549 Specification for Polystyrene Molding and Extrusion Materials (PS)[12]
D 4550 Specification for Thermoplastic Elastomer-Ether-Ester (TEEE)[12]
D 4617 Specification for Phenolic Compounds (PF)[12]
D 4634 Specification for Styrene-Maleic Anhydride Materials (S/MA)[12]
D 4673 Specification for Acrylonitrile-Butadiene-Styrene (ABS) Molding and Extrusion Materials[12]
D 4745 Specification for Filled Compounds of Polytetrafluoroethylene (PTFE) Molding and Extrusion Materials[12]
D 4812 Test Method for Unnotched Cantilever Beam Impact Strength of Plastics[12]
D 4894 Specification for Polytetrafluoroethylene (PTFE) Granular Molding and Ram Extrusion Materials[12]
D 4895 Specification for Polytetrafluoroethylene (PTFE) Resins Produced from Dispersion[12]
D 4976 Specification for Polyethylene Plastics Molding and Extrusion Materials[12]
D 5021 Specification for Thermoplastic Elastomer–Chlorinated Ethylene Alloy (TECEA)[12]
D 5046 Specification for Fully Crosslinked Elastomeric Alloys (FCEAs)[12]
D 5138 Specification for Liquid Crystal Polymers (LCP)[12]
D 5203 Specification for Polyethylene Plastics Molding and Extrusion Materials from Recycled Post-Consumer HDPE Sources[12]
D 5279 Test Method for Measuring the Dynamic Mechanical Properties of Plastics in Torsion[12]
D 5420 Test Method for Impact Resistance of Flat, Rigid Plastic Specimen by Means of a Striker Impacted by a Falling Weight (Gardner Impact)[12]
D 5436 Specification for Cast Poly(Methyl Methacrylate) Plastic Rods, Tubes, and Shapes[12]
D 5628 Test Method for Impact Resistance of Flat, Rigid Plastic Specimens by Means of a Falling Dart (Tup or Falling Weight)[12]
D 5676 Specification for Recycled Polystyrene Molding and Extrusion Materials[12]
D 5990 Classification System for Polyketone Injection and Extrusion Materials (PK)[12]
D 6339 Specification for Syndiotactic Polystyrene Molding and Extrusion (SPS)[12]
D 6358 Classification System for Poly(Phenylene Sulfide) Injection Molding and Extrusion Materials Using ISO Methods[12]
D 6360 Practice for Enclosed Carbon-Arc Exposures of Plastics[12]
D 6457 Specification for Extruded and Compression Molded Rod and Heavy-Walled Tubing Made from Polytetrafluoroethylene (PTFE)[12]
D 6585 Specification for Unsintered Polytetrafluoroethylene (PTFE) Extruded Film or Tape[12]
E 29 Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications[14]
E 84 Test Method for Surface Burning Characteristics of Building Materials[15]
E 96 Test Methods for Water Vapor Transmission of Materials[16]
E 104 Practice for Maintaining Constant Relative Humidity by Means of Aqueous Solutions[17]
E 162 Test Method for Surface Flammability of Materials Using a Radiant Heat Energy Source[15]
F 372 Test Method for Water Vapor Transmission of Flexible Barrier Materials Using an Infrared Detection Technique[6]

TABLE 1 Standard Symbols for Generic Families With Referenced Standards and Cell Tables

Standard Symbol	Plastic Family Name	ASTM[A] Standard	Suggested Reference Cell Tables for Materials Without an ASTM Standard[B]	
			Unfilled	Filled
ABA	acrylonitrile-butadiene-acrylate		E	
ABS	acrylonitrile-butadiene-styrene	D 3965 D 4673		
AMMA	acrylonitrile-methyl methacrylate		E	
ARP	aromatic polyester	(see LCP)		
ASA	acrylonitrile-styrene-acrylate		E	
CA	cellulose acetate	D 706		
CAB	cellulose acetate butyrate	D 707		
CAP	cellulose acetate proprionate		E	D
CE	cellulose plastics, general		E	D
CF	cresol formaldehyde		H	H
CMC	carboxymethyl cellulose		E	
CN	cellulose nitrate		E	D
CP	cellulose propionate	D 1562		
CPE	chlorinated polyethylene		F	
CPVC	chlorinated poly(vinyl chloride)	D 4396, D 1784, D 5260, D 3915, D 4216		
CS	casein		H	H
CTA	cellulose triacetate		E	D
EC	ethyl cellulose	D 787	E	D
E-CTFE	ethylene-chlorotrifluoroethylene copolymer	D 3275		
EEA	ethylene-ethyl acrylate		F	
EMA	ethylene-methacrylic acid		F	
EP	epoxy, epoxide		H	H
EPD	ethylene-propylene-diene			
EPM	ethylene-propylene polymer		F	D
ETFE	ethylene-tetrafluoroethylene copolymer	D 3159		
EVA	ethylene-vinyl acetate		F	
FCEA	fully crosslinked elastomeric alloy	D 5046		
FEP	perfluoro (ethylene-propylene) copolymer	D 2116		
FF	furan formaldehyde	D 3296	H	H
IPS	impact polystyrene	(see PS)		
LCP	liquid crystal polymer	D 5138		
MF	melamine-formaldehyde		H	H
PA	polyamide (nylon)	D 4066		
PAEK	polyaryletherketone	D __		
PAI	polyamide-imide	D 5204	G	G
PARA	polyaryl amide			
PB	polybutene-1		F	
PBT	poly(butylene terephthalate)	(see TPES)		
PC	polycarbonate	D 3935		
PCTFE	polymonochlorotrifluoroethylene	D 1430, D 3595		
PDAP	poly(diallyl phthalate)		H	H
PE	polyethylene	D 1248, D 4976, D 3350, D 4020, D 5203		
PEBA	polyether block amide			
PEEK	polyetheretherketone			
PEI	polyether-imide	D 5205		
PEO	poly(ethylene oxide)	D __		
PESV	polyether sulfone			
PET	poly(ethylene terephthalate), general	(see TPES)		
PETG	glycol modified polyethylene terephthalate comonomer	(see TPES)		
PF	phenol-formaldehyde	D 4617		
PFA	perfluoro alkoxy alkane	D 3307		
PI	polyimide		G	G
PIB	polyisobutylene		F	
PK	polyketone	D 5990		
PMMA	Poly(methyl methacrylate)	D 788, D 5436		D
PMP	poly(4-methylpentene-1)		F	
POM	polyoxymethylene (acetal)	D 4181		
POP	polyphenylene oxide	(see PPE)		
PP	poly(propylene plastics)	D 4101		
PPA	polyphthalamide	D 5336		
PPE	polyphenylene ether	D 4349		
PPOX	poly(propylene oxide)			
PPS	poly(phenylene sulfide)	D 4067, D 6358		
PPSU	poly(phenyl sulfone)		G	G
PS	polystyrene	D 4549, D 5676		
PSU	polysulfone	D 6394		
PTFE	polytetrafluoroethylene	D 3294, D 3295, D 4441, D 4745, D 4894, D 4895, D 6457, D 6585		
PUR	polyurethane		F	D

TABLE 1 *Continued*

Standard Symbol	Plastic Family Name	ASTM[A] Standard	Suggested Reference Cell Tables for Materials Without an ASTM Standard[B]	
			Unfilled	Filled
PVAC	poly(vinyl acetate)		F	D
PVAL	poly(vinyl alcohol)		F	D
PVB	poly(vinyl butyral)		F	D
PVC	poly(vinyl chloride)	D 2287	F	D
PVDC	poly(vinyl idene chloride)		F	D
PVDF	poly(vinyl idene fluoride)	D 3222		
PVF	poly(vinyl fluoride)		F	D
PVFM	poly(vinyl formal)		F	D
PVK	poly(vinylcarbazole)		F	D
PVP	poly(vinyl pyrrolidone)		F	D
SAN	styrene-acrylonitrile	D 4203		
SB	styrene-butadiene		E	D
SI	silicone plastics		G	G
S/MA	styrene-maleic anhydride	D 4634		
SMS	styrene-methylstyrene		E	D
SPS	syndiotactic polystyrene	D 6339		
TECEA	thermoplastic elastomer-chlorinated ethylene alloy	D 5021		
TEEE	thermoplastic elastomer, ether-ester	D 4550		
TEO	thermoplastic elastomer-olefinic	D 5593		
TES	thermoplastic elastomer-stryenic	D 4474		
TPE	thermoplastic elastomer	(see individual material)		
TPES	thermoplastic polyester (general)	D 4507		
TPU	thermoplastic polyurethane	D 5476		
UF	urea-formaldehyde		H	H
UP	unsaturated polyester	D __		
VDF	vinylidene fluoride	D 5575		

[A]The standards listed are those in accordance with this classification. D __ indicates that a standard is being developed by the subcommittee responsible.

[B]Cell Tables A and B have been reserved for the referenced standards and will apply to unfilled and filled materials covered in those standards.

3. Terminology

3.1 *Definitions*—The definitions used in this classification system are in accordance with Terminology D 883.

4. Significance and Use

4.1 The purpose of this classification system is to provide a method of adequately identifying plastic materials in order to give industry a system that can be used universally for plastic materials. It further provides a means for specifying these materials by the use of a simple line call-out designation.

4.2 This classification system was developed to permit the addition of property values for future plastics.

5. Classification

5.1 Plastic materials shall be classified on the basis of their broad generic family. The generic family is identified by letter designations as found in Table 1. These letters represent the standard abbreviations for plastics in accordance with Terminology D 1600.

NOTE 4—For example: PA = polyamide (nylon).

5.1.1 The generic family is based on the broad chemical makeup of the base polymer. By its designation, certain inherent properties are specified.

TABLE 2 Reinforcement-Filler[A] Symbols[B] and Tolerances

Symbol	Material	Tolerance
C	Carbon and graphite fiber-reinforced	±2 percentage points
G	Glass-reinforced	±2 percentage points
L	Lubricants (for example, PTFE, graphite, silicone, and molybdenum disulfide)	depends upon material and process—to be specified.
M	Mineral-reinforced	±2 percentage points
R	Combinations of reinforcements and fillers	±3 percentage points (based on the total reinforcements or fillers, or both)

[A]Ash content of filled or reinforced materials may be determined using Test Method D 2584 where applicable.
[B]Additional symbols will be added to this table as required.

TABLE 3 Suffix Symbols and Requirements[A]

Symbol	Characteristic
A	Color (unless otherwise shown by suffix, color is understood to be natural) Second letter A = does not have to match a standard B = must match standard Three-digit number 001 = color and standard number on drawing 002 = color on drawing
B	Fluid resistance Second letter A = reference fuel A, ASTM D 471, aged 70 h at 23 ± 2°C B = reference fuel C, ASTM D 471, aged 70 h at 23 ± 2°C C = ASTM #1 oil, ASTM D 471, aged 70 h at 100 ± 2 °C D = IRM 902 oil, ASTM D 471, aged 96 h at 100 ± 2°C E = IRM 903 oil, ASTM D 471, aged 70 h at 100 ± 2°C F = Distilled water, ASTM D 471, aged 70 h at 100 ± 2°C Three digit number is obtained from Suffix Table 1. It indicates change in hardness, tensile strength, elongation, and volume. Example: BC 132 specifies that material, after aging in ASTM #1 oil for 70 h at 100°C, can have changed no more than 2 Shore D points, 5 % tensile strength, 15 % elongation, and 5 % in volume.
C	Melting point—softening point Second letter B = ASTM D 1525, load 10 N, Rate A (Vicat) C = ASTM D 1525, load 10 N, Rate B (Vicat) D = ASTM D 3418 (Transition temperature DSC/DTA) (ISO 11357-1 and 11357-3) G = ISO 306, load 10 N, heating rate 50°C/h (Vicat) H = ISO 306, load 10 N, heating rate 120°C/h (Vicat) I = ISO 306, load 50 N, heating rate 50°C/h (Vicat) J = ISO 306, load 50 N, heating rate 120°C/h (Vicat) K = ASTM D 1525, load 50 N, Rate A (Vicat) L = ASTM D 1525, load 50 N, Rate B (Vicat) Three-digit number = minimum value° C
E	Electrical Second letter A = dielectric strength (short-time), ASTM D 149 (IEC 243) Three-digit number × factor of 0.1 = kV/mm, min B = dielectric strength (step by step), ASTM D 149 (IEC 243) Three-digit number × factor of 0.1 = kV/mm, min C = insulation resistance, ASTM D 257 (IEC 93) Three-digit number × factor of 10^{14} = Ω, min D = dielectric constant at 1 MHz, ASTM D 150, max (IEC 250) Three-digit number × factor of 0.1 = value E = dissipation factor at 1 MHz, ASTM D 150, max (IEC 250) Three-digit number × factor of 0.0001 = value F = arc resistance, ASTM D 495, min Three-digit number = value G = volume resistivity, ASTM D 257 (IEC 93) Three-digit number × factor of 10^{14} = Ω-cm, min H = comparative tracking index, ASTM D 3638, ac frequency, 50 Hz, 0.1 % ammonium chloride (IEC 112) Three-digit number = V, min J = volume resistivity, ASTM D 257 (IEC 93), Ω-cm K = surface resistivity, ASTM D 257 (IEC 93), Ω (per square) First digit indicates: 1 = minimum requirement 2 = maximum requirement Final two digits indicate the exponential value of the base 10 Example: EJ206 specifies a maximum volume resistivity of 10^6Ω-cm
F	Flammability Second letter A = ASTM D 635 (burning rate) (IEC 60695-11-10) 000 = to be specified by user B = ASTM D 2863 (oxygen index) (ISO 4589) Three-digit number = value %, max C = ASTM D 1929, Procedure A (flash-ignition)

TABLE 3 *Continued*

Symbol	Characteristic
	Three-digit number = value,° C, min
	D = ASTM D 1929, Procedure B (self-ignition)
	Three-digit number = value,° C, min
	E = ASTM D 3713
	000 = to be specified by user
	F = ASTM D 3801
	000 = to be specified by user
	G = ASTM E 162
	First two digits indicate minimum specimen thickness
	00 to be specified; 05 3.00 mm
	01 0.25 mm; 06 6.00 mm
	02 0.40 mm; 07 9.00 mm
	03 0.80 mm; 08 12.70 mm
	04 1.60 mm; 09 >12.70 mm
	Third digit indicates the flame spread
	1 15 max; 5 100 max
	2 25 max; 6 150 max
	3 50 max; 7 200 max
	4 75 max; 8 >200
	H = E84
	000 = to be specified by user
	J = FMVSS 302 (ISO 3795)
	000 = to be specified by user
	K = density of smoke, ASTM D 2843
	000 = to be specified by user
	L = UL 94 (IEC 60695-11-10)
	First digit indicates minimum specimen thickness
	Molding Materials Thin Films
	mm; µm
	0 to be specified; to be specified
	1 0.25; 25.0
	2 0.40; 50.0
	3 0.80; 75.0
	4 1.60; 100.0
	5 2.50; 125.0
	6 3.00; 150.0
	7 6.00; 175.0
	8 12.70; 200.0
	9 >12.70; >200.0
	Second digit indicates type of flame test
	1 = Vertical (94V)
	1 = Horizontal (94H)
	3 = 125mm flame (94-5V)
	4 = Vertical thin materials (94VTM)
	Third digit indicates the flame rating
	0 = (94V/94VTM) 0 - refer to UL94
	1 = (94V/94VTM) 1 - refer to UL94
	2 = (94V/94VTM) 2 - refer to UL94
	3 = (94HB) 1 - burn rate < 40 mm/min
	4 = (94HB) 2 - burn rate < 75 mm/min
	5 = (94-5V) A no holes on plaques
	6 = (94-5V) B with holes on plaques
	7 = (94 foam) 1 refer to UL94
	8 = (94 foam) 2 refer to UL94
	9 = (94 foam) H refer to UL94
G	Specific gravity
	Second letter A = ASTM D 792 (tolerance ± 0.02) (ISO 1183 Method A)
	B = ASTM D 792 (tolerance ± 0.05) (ISO 1183 Method A)
	C = ASTM D 792 (tolerance ± 0.005) (ISO 1183 Method A)
	D = ASTM D 1505 (tolerance ± 0.02)
	E = ASTM D 1505 (tolerance ± 0.05)
	F = ASTM D 1505 (tolerance ± 0.005)
	H = ASTM D 792/D 1505 (max)
	L = ASTM D 792/D 1505 (min)
	Three-digit number × factor of 0.010 = requirement value
H	Heat resistance, properties at temperature
	Second letter A = heat aged for 70 h at 100 ± 2°C, ASTM D 573
	B = heat aged for 70 h at 150 ± 2°C, ASTM D 573
	C = heat aged for 70 h at 200 ± 2°C, ASTM D 573
	Three-digit number is obtained from Suffix Table 1. It indicates change in hardness, tensile strength, elongation and volume.
	Second letter D = tested at 100 ± 2°C
	E = tested at 125 ± 2°C
	F = tested at 150 ± 2°C
	Three-digit numbers obtained from Suffix Table 2. It indicates tensile strength, elongation, and tear strength.

Wed Feb 02 02:00:23 2005

TABLE 3 *Continued*

Symbol	Characteristic
	Example: HE565 specifies that the material has a minimum of 15 MPA tensile strength, 400 % elongation, and a tear strength of 40 kN/m when tested at 125°C.
	Second letter L = low-temperature brittleness, ASTM D 2137
	Three-digit number indicates the temperature (°C) above which the material is non-brittle. Example: HL055 material is non-brittle according to ASTM D 2137a, above – 55°C.
I	Not to be used at this time
J	Hardness
	Second letter A = ASTM D 2240 (Shore A) tolerance ±5 (ISO 868)
	B = ASTM D 2583 (Barcol), min
	D = ASTM D 2240 (Shore D) tolerance ±3 (ISO 868)
	E = ASTM D 785 (Rockwell E), min
	K = ASTM D 785 (Rockwell K), min
	L = ASTM D 785 (Rockwell L), min (ISO 2039-2)
	M = ASTM D 785 (Rockwell M), min (ISO 2039-2)
	R = ASTM D 785 (Rockwell R), min (ISO 2039-2)
	Three-digit number = value
K	Tensile strength
	Second letter B = at break, ASTM D 638
	C = at rupture, ASTM D 412
	D = tensile stress at break, ISO 527-1 and 527-2
	E = tensile stress at 50 % strain, ISO 527-1 and 527-2
	Three-digit number = value, MPa, min
	Example: KC040 specifies a tensile strength at rupture of 40 MPa
	M = tensile stress, ASTM D 412
	First digit indicates the elongation at which the tensile stress is measured.
	1 = 25 %
	2 = 100 %
	3 = 300 %
	Final two digits = value, MPa, min
	N = tensile modulus, ISO 527-1 and 527-2
	Three-digit number × factor of 100 = value, MPa, min
	S = tensile set, ASTM D 412
	First digit indicates the elongation at which the set is measured.
	1 = 50 %
	2 = 100 %
	3 = at break
	4 = 200 %
	Final two digits indicate the maximum percent set.
	Example: KS208 specifies a maximum tensile set of 8 % when tested at 100 % extension.
	Y = yield, ASTM D 638
	X = tensile stress at yield, ISO 527-1 and 527-2
	Three-digit number = value, MPa, min
L	Elongation
	Second letter B = break, ASTM D 638
	C = break, ASTM D 412
	D = break, ISO 527
	Three-digit number = value, %, min
	R = resilience, ASTM D 2632
	First digit:
	1 = minimum
	2 = maximum
	Final two digits indicate percent rebound
	Example: LR 150 specifies a minimum rebound of 50 %
	T = tear strength, ASTM D 624 Die C
	Three-digit number = value, kN/m, min
	Y = yield, ASTM D 638
	X = yield, ISO 527
	Three-digit number = value, %, min
M	Moisture resistance or content
	Second letter A = ASTM D 570 (24-h immersion) (ISO 62)
	B = ASTM D 570 (2-h immersion)
	C = ASTM D 570 (long-term immersion)
	D = ASTM D 570 (½-h boiling water immersion)
	E = ASTM D 570 (48 h at 50°C immersion)
	F = ASTM D 789 (ISO 15512, Method B), moisture content
	Three-digit number × factor of 0.01 = value, percent max
N	Flexural strength
	Second letter A = ASTM D 790, specimen = 3.2 × 13 × 76 mm, speed = 1.3 mm/min
	B = ASTM D 790, specimen = 6.4 × 13 × 127 mm, speed = 2.7 mm/min
	C = ISO 178, specimen = 80 × 10 × 4 mm, speed = 2 mm/min, 64-mm span
	Three-digit number = value, MPa, min
O	Not to be used at this time
P	Impact resistance
	Second letter A = ASTM D 256 (Test Method A, Izod)

	2 = ASTM D 5420 Configuration GB
	3 = ASTM D 5420 Configuration GC
	4 = ASTM D 5420 Configuration GD
	5 = ASTM D 5420 Configuration GE
	Two-digit number × 10 = value, J min
	H = ISO 6603-1, specimen = 2-mm thickness
	Three-digit number = value, J
	J = low-temperature brittleness, ISO 974
	Three-digit number = −°C, max
	K = ASTM D 4812
	Three-digit number × factor 10 = value, J/m, min
	000 = no break
	L = Low temperature brittleness, ASTM D 746 (Procedure A)
	Three-digit number = −°C, max
	M = ISO 180/1A (Izod), specimen = 80 · 10 · 4 mm
	N = ISO 179/1A (Charpy), specimen = 80 · 10 · 4 mm
	Three-digit number × factor 0.1 = value kJ/m^2, min
	S = ASTM D 1822, Type S, 3 mm thick
	T = ASTM D 1822, Type L, 3 mm thick
	Three-digit number = value, kJ/m^2, min
Q	Compressive strength
	Second letter A = ASTM D 695
	B = ISO 604
	Three-digit number = value, MPa, min
	D = compression deflection, ASTM D 575, Test Method A
	First digit = % deflection
	1 = 5 %
	2 = 10 %
	3 = 15 %
	4 = 20 %
	5 = 25 %
	6 = 30 %
	7 = 40 %
	8 = 50 %
	Final two digits indicate minimum load in MPa
	Example: QD445 specifies a minimum load of 45 MPa when deflected 20 %
	S = compression set, ASTM D 395, (Test Method B), run for 22 h.
	First digit = test temperature
	1 = 23± 2°C
	2 = 70± 2°C
	3 = 100± 2°C
	4 = 125± 2°C
	5 = 150± 2°C
	Final two digits indicate maximum percent set.
R	Volatile loss, gas and vapor permeability
	Second letter A = ASTM D 1203, Test Method A
	B = ASTM D 1203, Test Method B
	C = ASTM D 2288
	D = ASTM D 2584
	Three-digit number × factor of 0.01 = value, percent, max
	E = ASTM D 3985
	F = ASTM D 1434 (Test Method M)
	G = ASTM E 96 (Test Method E)
	H = ASTM F 372
	First digit 1 = oxygen

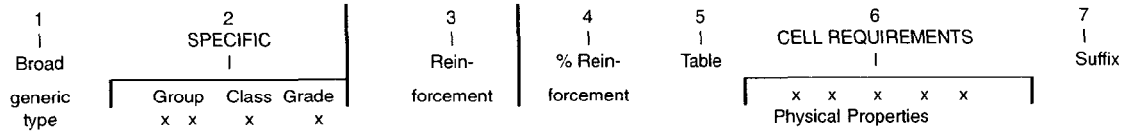
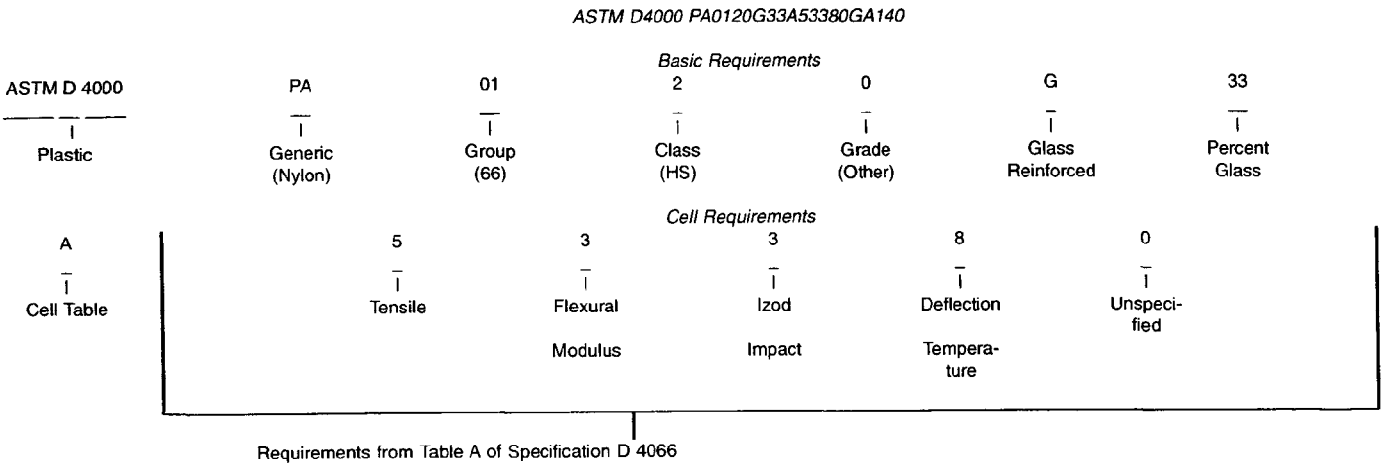
ASTM D 4000 Line Call-Out



1 = Two or more letters identify the generic family based on Terminology D 1600.
2 = Four digits identify the specific chemical group, the modification or use class, and the grade by viscosity or level of modification. A basic property table will provide property values.
3 = One letter indicates reinforcement type.
4 = Two digits indicate percent of reinforcement.
5 = One letter refers to a cell table listing of physical specifications and test methods.
6 = Five digits refer to the specific physical parameters listed in the cell table.
7 = Suffix codes indicate special requirements based on the application, and identify special tests (see Section 7).

Copyright by the ASTM International
Wed Feb 02 02:00:24 2005



5.2 The generic family is classified into groups according, in general, to the chemical composition. These groups are further subdivided into classes and grades as shown in the basic property table that applies. The letter designation applicable is followed by a four-digit number indicating group, class, and grade. The first two digits indicate the group, the third digit the class, and the fourth digit the grade.

NOTE 5—The previous edition of this standard used three digits for group, class, and grade; 0120 is equivalent to 120.

NOTE 6—An example using the group, class, and grade is as follows: PA0122 would indicate: PA = polyamide (nylon), 01 (group) = 66 nylon, 2 (class) = heat stabilized, and 2 (grade) with requirements given in the (PA) basic property table of Specification D 4066.

5.2.1 The basic property tables have been developed to identify the commercially available unreinforced plastics into groups, classes, and grades. These tables are found in the standards listed in Table 1.

5.2.1.1 Where a standard does not exist for this classification system the letter designation for the generic family will be followed by four O's and the use of cell table that applies (see 5.4.2).

NOTE 7—*Example*—PI0000 would indicate a polyimide plastic (PI) from Table 1, with 0000 indicating no basic property table and G12360 requirements from Cell Table G.

5.3 Reinforced versions of the basic materials are identified by a single letter that indicates the reinforcement used and two digits that indicate the nominal quantity in percent by weight. Thus, a letter designation G for glass-reinforced and 33 for percent of reinforcement, G33, specifies a filled material with a nominal glass level of 33 %. The reinforcement letter designations and associated tolerance levels are shown in Table 2.

NOTE 8—The type and amount of reinforcement will be shown on supplier's technical data sheet unless the materials are proprietary. If necessary, additional control of these reinforcements shall be accomplished by the use of the suffix part of the system (Section 7).

5.4 To facilitate the identification of new, special, and reinforced materials where basic property tables are not provided in a material specification, cell tables have been incorporated in this document. These tables should be used in the same manner as the cell tables that appear in the material specifications.

5.4.1 Although the values listed in cell tables include the range of properties available in existing materials, users should not infer that every possible combination of properties exists or can be obtained.

5.4.2 The requirements for special or reinforced materials will use the classification system as described by the addition of a single letter that indicates the proper cell table in which the properties are listed. A specific value is designated by the cell number for each property in the order in which they are listed in the table. When a property is not to be specified, a zero is entered as the cell number. Likewise, when an acceptable value is not available in the cell table, the number 9 should be used and a suffix used indicating the specific value (see 7.3). Thus, the letter designation "A" for cell table and 53380 for property values shall always be written A53380. The cell tables that may be used for each generic family are listed in Table 1.

NOTE 9—An example of a reinforced plastic identified by this classification system is as follows. The designation PA0120G33A53380 indicates the following with the material requirements from Specification D 4066:

PA0120	=	Nylon 66 heat stabilized from Table PA of Specification D 4066.
G33	=	Glass reinforced with 33 % glass, nominal.
A	=	Table A (D 4066) for property requirements.
5	=	Tensile strength, 175 MPa, min.
3	=	Flexural modulus, 7500 MPa, min.
3	=	Izod impact, 75 J/m, min.
8	=	Deflection temperature, 235°C, min, and
0	=	Unspecified.

6. Basic Requirements

6.1 The cell tables included as a part of the listed referenced standard shall be used to develop a line call-out for the materials listed in Table 1 çovered by a material standard.

6.2 The cell tables included in this classification shall be used to develop a line call-out for the materials not covered by

Copyright by the ASTM International
Wed Feb 02 02:00:24 2005

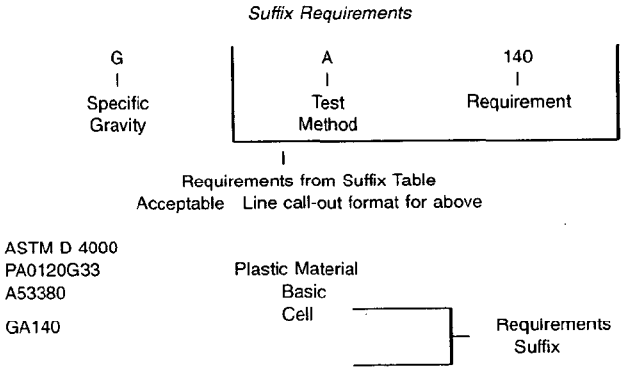
material standards (Table 1). When the existing cell table does not adequately describe the material, then suffixes may be used in place of a cell table designation.

6.3 A line call-out assembled using this classification system becomes a specification. The line call-out shall contain the broad and specific type of plastic, together with the appropriate identifiers followed by special suffix requirements, as they apply. The following summarizes the line call-out and the entire system as detailed in this standard.

7. Suffix Requirements

7.1 When requirements are needed that supersede or supplement the property table or cell table requirements, they shall be specified through the use of suffixes. In general, the first suffix letter indicates the special requirement needed and the second letter indicates the condition or test method, or both, with a three-digit number indicating the specific requirement. The suffixes that may be used are listed in Table 3.

7.2 Basic requirements from property or cell tables, as they apply, are always in effect unless these requirements are superseded by special suffix requirements in the line call-out.



NOTE 10—When using the suffixes for additional requirements of the material, the user must keep in mind that not all tests are routinely conducted by the supplier. When these requirements are necessary to identify particular characteristics important to specific applications they shall be agreed upon between user and supplier.

7.3 The following is an example of a line call-out specification for a reinforced nylon:

7.4 When a standard for a material is listed in Table 1, the requirements of the referenced standard apply. If desired, the referenced standards may be used since a similar system is used in each document. When the requirements for a material are included in this standard, the following sections are applicable.

8. General Requirements

8.1 The composition of the specified material shall be uniform and shall conform to the requirements specified herein.

9. Detail Requirements

9.1 The material shall conform to the requirements prescribed in the table (basic property, reinforced, cell, and suffix) as they apply.

9.2 For the purpose of determining conformance with this specification, all specified limits, in this standard are absolute limits as defined in Practice E 29.

9.3 With the absolute method, an observed value or a calculated value is not rounded, but is to be compared directly with the specified limiting value. Conformance or nonconformance with the specification is based on this comparison.

10. Sampling

10.1 Sampling shall be statistically adequate to satisfy the requirements of 15.4. A lot of material shall be considered as a unit of manufacture as prepared for shipment, and may consist of a blend of two or more "production runs" or batches.

11. Numbers of Tests

11.1 The number of tests conducted shall be consistent with the requirements of Sections 10 and 15.4.

12. Specimen Preparation

12.1 The test specimens shall be molded as specified for the specific materials under test in the ASTM standard specifications for the materials.

13. Conditioning

13.1 Condition the test specimens at 23 ± 2°C and 50 ± 5 % relative humidity for not less than 40 h prior to testing, in accordance with Procedure A of Practice D 618 for those tests where conditioning is specified unless otherwise directed in the ASTM standard specification for the material.

13.2 Conduct tests in the standard laboratory atmosphere of 23 ± 2°C and 50 ± 5 % relative humidity unless otherwise directed in the ASTM standard specification for the material.

13.3 For materials sensitive to atmospheric exposure, special preparations for conditioning and test conditions should be adhered to as provided in the referenced standard for the material.

14. Test Methods

14.1 Determine the properties enumerated in this classification system by means of the test methods referenced.

15. Inspection and Certification

15.1 Inspection and certification of the material supplied under this classification system shall be for conformance to the requirements specified herein.

15.2 Lot-acceptance inspection shall be the basis on which acceptance or rejection of the lot is made. The lot-acceptance inspection shall consist of those tests which ensure process control during manufacture as well as those necessary to ensure certifiability in accordance with 15.4.

15.3 Periodic check inspection shall consist of the tests specified for all requirements of the material under this classification system. Inspection frequency shall be adequate to ensure the material is certifiable in accordance with 15.4.

15.4 Certification shall be that the material was manufactured, sampled, tested, and inspected in accordance with this classification system and that average values meet the requirements at a confidence level of 95 %.

15.5 A report of the test results shall be furnished when requested. The report shall consist of results of the lot-acceptance inspection for the shipment and the results of the most recent periodic-check inspection.

16. Packaging, Packing, and Marking

16.1 Provisions of Practice D 3892 apply for packaging, packing, and marking of plastic materials.

17. Keywords

17.1 classification; classification system; line callout; plastic; plastic materials

SUMMARY OF CHANGES

This section identifies the location of selected changes to this classification system. For the convenience of the user, Committee D20 has highlighted those changes that may impact the use of this classification system. This section may also include descriptions of the changes or reasons for the changes, or both.

D 4000 – 01:

(*1*) Second letters J and K added for Symbol E in Table 3.

(*2*) Second letter G added for Symbol W in Table 3.

(*3*) Referenced Documents were updated to reflect the revisions to Table 3.

D 4000 – 00a:

(*1*) Referenced Documents were updated to reflect the revisions to Table 3.

(*2*) Table 3, Symbol B: ES 27 was removed; incorporated in Test Method D 471.

(*3*) Table 3, Symbol C: Removed second letters A and E and added second letters K and L for Test Method D 1525, 50-N load.

(*4*) Table 3, Symbol D: Removed.

(*5*) Table 3, Symbol E: Added expression of results for second letter H.

(*6*) Table 3, Symbol F: Substituted IEC reference for Second Letter A to replace withdrawn ISO standard. Deleted repetition of the second letter L which referenced a deleted ASTM standard, Test Method F 814.

(*7*) Table 3, Symbol K: Changed second letter M from tensile modulus to tensile stress.

(*8*) Table 3, Symbol M: Added ISO reference for second letter F.

(*9*) Table 3, Symbol S: Deleted references to withdrawn standards, ASTM Test Method D 2445 and ISO 537. Added ISO 6721-1 and -2 as references for second letter M. Deleted second letter P as it was a repeat of second letter M.

(*10*) Table 3, Symbol U: Added second letter N to permit expression of flexural modulus by ISO 178 as a minimum value.

(*11*) Table 3, Symbol W: Added new ASTM standards for evaluating weather resistance.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: D 4024 – 00

An American National Standard

Standard Specification for Machine Made "Fiberglass" (Glass-Fiber-Reinforced Thermosetting Resin) Flanges[1]

This standard is issued under the fixed designation D 4024; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers reinforced-thermosetting resin flanges other than contact-molded flanges. Included are requirements for materials, workmanship, performance, and dimensions.

1.2 Flanges may be produced integrally with a pipe or fitting, may be produced with a socket for adhesive bonding to a pipe or fitting, or may be of the type used in conjunction with either a metallic or nonmetallic backup ring.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are given for information only. In cases where materials, products, or equipment are available only in SI units, inch-pound units are omitted.

1.4 The following precautionary caveat pertains only to the test methods portion, Section 11, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

NOTE 1—Contact molded flanges are covered in Specification D 5421 and referenced in Specification D 5685.

NOTE 2—There is no similar or equivalent ISO standard.

NOTE 3—For purposes of this specification, polyester includes vinylester resins.

2. Referenced Documents

D 5685 Specification for "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pressure Pipe Fittings[3]

F 412 Terminology Relating to Plastic Piping Systems[3]

2.2 *ANSI Standards:*

B 16.1 Cast Iron Pipe Flanges and Flanged Fittings[5]

B 16.5 Pipe Flanges and Flanged Fittings[5]

3. Terminology

3.1 *Definitions:*

3.1.1 *General*—Definitions are in accordance with Terminology D 883 or Terminology F 412. Abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for reinforced-thermosetting-resin pipe is RTRP.

4. Classification

4.1 *General*—This specification covers machine-made reinforced-thermosetting-resin flanges defined by type (method of manufacture), grade (generic type of resin), class (configuration of joining system), and pressure rating. Flanges complying with this specification are also given numerical classifications relating to rupture pressure, sealing test pressure, and bolt torque limit.

4.1.1 *Types*:

4.1.1.1 *Type 1*—Filament-wound flanges manufactured by winding continuous fibrous glass strand roving or roving tape, either preimpregnated or impregnated during winding, into a flange cavity under controlled tension.

4.1.1.2 *Type 2*—Compression-molded flanges made by applying external pressure and heat to a molding compound that is confined within a closed mold.

4.1.1.3 *Type 3*—Resin-transfer-molded flanges manufactured by pumping a thermosetting resin into glass reinforcements that have been cut to size and clamped between matched molds.

4.1.1.4 *Type 4*—Centrifugally-cast flanges are made by applying resin and reinforcement to the inside of a mold that is

[1] This specification is under the jurisdiction of ASTM Committee D-20 on Plastics and is the direct responsibility of Subcommittee D20.23 on Reinforced Plastic Piping Systems and Chemical Equipment.

rotated and heated, subsequently polymerizing the resin system.

4.1.2 *Grades*:

4.1.2.1 *Grade 1*—Epoxy resin.

4.1.2.2 *Grade 2*—Polyester resin.

4.1.2.3 *Grade 3*—Furan resin.

4.1.3 *Classes*:

4.1.3.1 *Class 1*—Integrally-molded flange manufactured directly on a pipe section, pipe stub, or fitting.

4.1.3.2 *Class 2*—Taper to taper adhesive joint flange manufactured with a tapered socket to be used in conjunction with a pipe or fitting with a tapered spigot section and a suitable adhesive. This joining method provides an interference fit over the entire length of the bond line.

4.1.3.3 *Class 3*—Straight-taper adhesive joint flange manufactured with a tapered socket to be used with a pipe or fitting with an untapered spigot section and a suitable adhesive. This joining method provides an interference fit at the bottom of the socket.

4.1.3.4 *Class 4*—Straight adhesive joint flange manufactured with an untapered socket for use with a pipe or fitting with an untapered spigot and a suitable adhesive. This joint provides no interference fit.

4.1.4 *Pressure Rating*—Pressure rating shall be categorized by a single letter designation. Pressure designations are shown in Table 1.

4.1.5 Rupture pressure, sealing test pressure, and bolt torque limit shall be categorized by single arabic number designations as indicated by the cell classification system of Table 2.

4.2 *Designation Code*—The flange designation code shall consist of the abbreviation RTR, followed by the type, grade, and class in arabic numerals, the pressure rating category as a capital letter, and three arabic numbers identifying the cell classification designations of the rupture pressure, sealing test pressure, and the bolt torque limit, respectively. Thus, a complete flange designation code shall consist of three letters, three numerals and one letter, and three numerals.

4.2.1 *Example*—RTR-112D-334. This designation describes a filament-wound, glass fiber-reinforced epoxy resin flange with a taper to taper adhesive joining system. The flange has a 200 psi (1.4 MPa) pressure rating, a burst pressure in excess of 600 psi (4.1 MPa), a sealing test pressure of 225 psi (1.6 MPa), and a bolt torque limit greater than 75 lbf·ft (102 N·m).

NOTE 4—Flanges with identical classification from different manufacturers may not be interchangeable due to nonstandardization of pipe or socket diameter, socket length, taper angle, or combination thereof.

TABLE 1 Pressure Categories

Designation	Pressure Rating	
	psi	MPa
A	50	0.35
B	100	0.69
C	150	1.03
D	200	1.38
E	250	1.72
F	300	2.07
G	400	2.76
H	500	3.45

5. Materials and Manufacture

5.1 Flanges manufactured in accordance with this specification shall be composed of reinforcement imbedded in or surrounded by cured thermosetting resin. The composite structure may contain granular or platelet fillers, thixotropic agents, pigments, or dyes.

5.2 The resins, reinforcements, and other materials, when combined as composite structure, shall produce a flange that will meet the performance requirements of this specification.

6. Performance Requirements

6.1 Flanges shall meet the following performance requirements when joined for testing according to the manufacturer's recommended practice for field installation:

6.1.1 *Sealing*—Flanges shall withstand a pressure of at least 1.5 times the rated design pressure without leakage when tested in accordance with 11.4.

6.1.2 *Short-Term Rupture Strength*—Flanges shall withstand a hydrostatic load of at least four times their rated design pressure without damage to the flange when tested in accordance with 11.5.

6.1.3 *Bolt Torque*—Flanges shall withstand, without visible sign of damage, a bolt torque of at least 1.5 times that recommended by the manufacturer for sealing of the flange at its rated pressure when tested in accordance with 11.6.

7. Content Requirements

7.1 *Percentage Extractable Material*— Flanges shall contain no more than 5 % extractable material when tested in accordance with Annex A1.

7.2 *Recycled or Repprocessed Thermosetting Plastics*—Flanges shall not contain any recylced or reprocessed thermosetting plastics which might otherwise be added as fillers.

8. Dimensions

8.1 *Dimensions and Tolerances*:

8.1.1 *Flange and Bolt Dimensions*—Flanges of 24 in. (610 mm) or smaller diameter shall conform to the values given in Table 3 for bolt circle, number and size of bolt holes, and outside diameter. Flanges larger than 24 in. (610 mm) in diameter shall conform to the values for bolt circle, number and size of bolt holes, and outside diameter for Class 125 cast iron flanges in ANSI B 16.1. The tolerance for the flange dimensions provided in Table 3 shall be the same as those contained in ANSI B 16.1.

8.1.2 *Flange Face*—The flange face shall be perpendicular to the axis of the fitting within ½°, and shall be flat to ±1/32 in. (1 mm) for sizes up to and including 18 in. (457 mm) diameter and ±1/16 in. (2 mm) for larger diameters.

8.1.3 *Washer Bearing Surface*—Washer bearing surface shall be flat and parallel to the flange face within ±1°.

8.2 *Pipe Stop*—Each adhesive joined flange shall provide sufficient taper or a diametral constriction to act as a stop during adhesive joining so that the pipe stub cannot project beyond the face of the flange.

9. Workmanship, Finish, and Appearance

9.1 Flanges shall be free as commercially practical of defects, including indentations, delaminations, bubbles, pinholes, foreign inclusions, and resin-starved areas.

18	25.00 (635.0)	22.75 (577.8)	1.25 (31.7)	16	1 1/8 (28.6)
20	27.50 (698.5)	25.00 (635.0)	1.25 (31.7)	20	1 1/8 (28.6)
24	32.00 (812.8)	29.50 (749.3)	1.38 (35.1)	20	1 1/4 (31.7)

[A] Dimensions conform to ANSI B 16.5 for Class 150 steel flanges.
[B] For larger sizes, see 8.1.1.

10. Sampling

10.1 The rate of sampling of flanges for pressure rating verification shall be in accordance with Annex A2.

10.2 For individual orders, only those additional tests and number of tests specifically agreed upon between the purchaser and seller need be conducted.

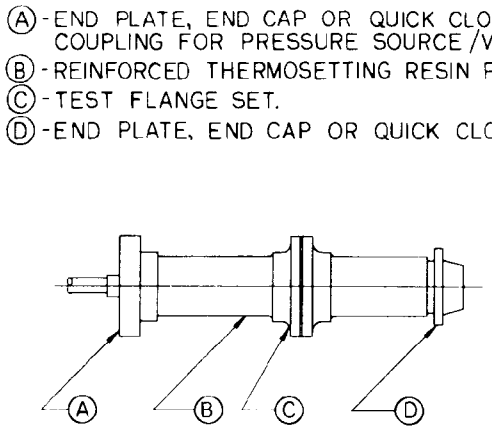
11. Test Methods

11.1 *Conditioning*—When conditioning is required, and in all cases of disagreement, condition the test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test, in accordance with Procedure A of Practice D 618.

11.2 *Test Conditions*—The tests may be conducted at ambient temperature and humidity conditions. When controlled environment testing is specified, tests shall be conducted in the Standard Laboratory Atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity. When elevated temperature testing is specified, the tests shall be conducted at the design operating temperature ±5.4°F (3°C).

11.3 *Dimensions and Tolerances*—Flange dimensions shall be measured with a micrometer of vernier calipers, or other suitable measuring devices accurate to within ±0.001 in. (±0.02 mm). Diameters shall be determined by averaging a minimum of four measurements, equally spaced circumferentially.

11.4 *Sealing*—Flanged components in general arrangement with Fig. 1 shall be bolted together using the gasket and bolt torque recommended for standard field installation by the flange manufacturer. The assembly shall then be pressure tested and be required to hold the test pressure for a period of 168 hours without leakage. Retorquing to the manufacturer's



Ⓐ End plate, end cap, or quick closure with coupling for pressure source/vent line
Ⓑ Reinforced thermosetting resin pipe (RTRP)
Ⓒ Test flange set
Ⓓ End plate, end cap, or quick closure

FIG. 1 Test Assembly Configuration

Wed Feb 02 02:01:20 2005

specified level after initial pressurization is permitted.

11.5 *Short-Term Rupture Strength*—Flanged components shall be tested in accordance with Test Method D 1599 with free-end closure except as herein noted. The pressure in the specimen shall be increased until failure of the flange occurs. Pressure testing in an atmospheric environment is permissible. Minimum failure time shall be 60 s; no restriction shall be placed on maximum time-to-failure. Leaking past the gasket interface is permissible during this test. Bolt torque may be increased as necessary during the test in order to minimize gasket leaking and to achieve the pressure necessary to cause flange failure. The assembly used for the test in 11.4 may be used for this test.

11.6 *Maximum Bolt Torque*—Using the gasket and hardware recommended by the flange manufacturer, bolt the flange against a flat face steel flange. Tighten the nuts by hand until they are snug. Prior to fit-up, the nuts, bolts, and washers should be well lubricated, using a nonfluid thread lubricant. Establish uniform pressure over the flange face by tightening bolts in 5 lbf·ft (7 N·m) increments according to the sequence shown in Fig. 2. For flanges with more than 20 bolts, similar alternating bolt tightening sequences shall be used. Increase the bolt torque uniformly until flange failure occurs or until all bolts have been torqued to five times the level recommended by the manufacturer for field installation practice to establish the bolt torque cell classification of the flange. Any sign of flange damage (crumbling, flaking, cracking, or other breaking) shall constitute failure.

NOTE 5—The torque limits determined by 11.6 apply only to flanges bolted up against a flat sealing surface. Significantly lower bolt torque value will normally be obtained when RTR flanges are bolted up against raised-faced flanges. When RTR flanges must be used against raised steel flange face, the flange manufacturer should be contacted for his torquing and installation recommendations.

12. Product Marking

12.1 Each flange shall be marked with the following information:

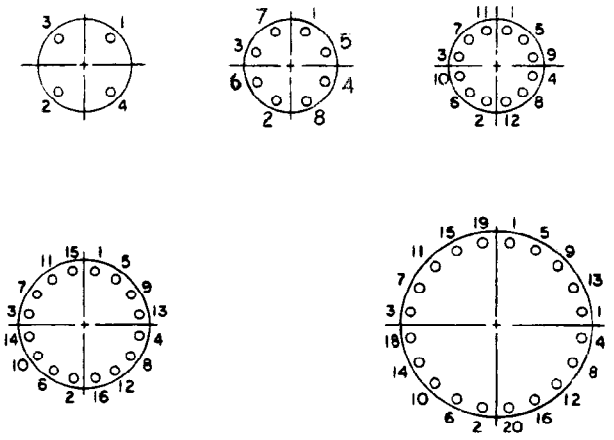

FIG. 2 Bolt Torquing Sequence

12.1.1 The designation "ASTM D 4024" indicating compliance with this specification,

12.1.2 Identification of the flange in accordance with the designation code in 4.2,

12.1.3 Nominal flange size, and

12.1.4 Manufacturer's name (or trademark) and product designation.

12.2 All required markings shall be legible and so applied as to remain legible under normal handling and installation practices.

13. Precision and Bias

13.1 No precision and bias statement can be made for this test method, since controlled round robin test programs have not been run.

NOTE 6—Thw wide variation in raw materials and constructions allowed in this specification make round robin testing difficult to apply.

14. Keywords

14.1 centrifugally-cast; compression-molded; filament-wound; furan; machine-made; polyester; resin-transfer; vinylester

ANNEXES

(Mandatory Information)

A1. TEST METHOD FOR PERCENTAGE EXTRACTABLE MATERIALS

A1.1 Scope

A1.1.1 This test method covers the procedure for determining the percentage extractable materials in RTR flanges.

A1.2 Summary of Test Method

A1.2.1 The test method consists of filing material from the flange, immersing this material in a solvent (methylene chloride), extracting the unreacted material and, by means of gravimetric analysis, determining the quantity of unreacted resin and residual solvent.

NOTE A1.1—For certain classes of resins, it may be necessary to select a different solvent in performing this test.

A1.3 Significance and Use

A1.3.1 This test method measures the amount of extractable material which includes unreacted resin and residual solvent.

A1.4 Apparatus

A1.4.1 *Beakers*, 100-mL

A1.4.2 *Beakers*, 50-mL

A1.4.3 *Graduate*, 25-mL

A1.4.4 *Magnetic Stirrer* and capsule (dental amalgam shaker).

A1.4.5 *Funnel* and filter paper (type) Grade 950, size 15 cm.

Copyright by the ASTM International
Wed Feb 02 02:01:20 2005

A1.4.6 *Hot Plate.*

A1.4.7 *Oven.*

A1.5 Procedure

A1.5.1 Remove 1 to 2 g of a representative sample by means of a clean file.

A1.5.2 Pulverize the rough sample to a fine powder in a magnetic stirrer capsule. Each capsule should be pulverized for about 3 min.

A1.5.3 Accurately weigh the pulverized sample in a tared 50-mL beaker.

A1.5.4 *Gravimetric Analysis*:

A1.5.4.1 Add 25 mL of methylene chloride (or other suitable solvent) to the pulverized sample and mix.

A1.5.4.2 Place mixture on a steam bath or hot plate for 10 min.

NOTE A1.2—The solvent should not be heated above its boiling point (for methylene chloride, 104°F (40°C)).

A1.5.4.3 Let mixture cool for 10 min and filter into a tared 100-mL beaker. Wash mixture out of the 50-mL beaker and add washing to filtrate. It is very important to wash the 50-mL beaker and filter paper with methylene chloride several times to be sure all extractable material passes through the filter.

A1.5.4.4 Place filtrate in oven and evaporate methylene chloride. Oven temperature should be 194 to 212°F (90 to 100°C).

A1.5.4.5 After solvent evaporates, let beaker cool in a desiccator for 15 min.

A1.5.4.6 Weigh the beaker.

A1.5.4.7 Repeat steps 4, 5, and 6 until a constant weight is reached.

NOTE A1.3—It has been found that a 25-min drying time is satisfactory.

A1.6 Calculation

A1.6.1 Calculate the percentage extractable materials as follows:

$$\% \text{ extractable} = \frac{L}{W \times R} \times 100$$

where:

L = actual weight of residue = weight of beaker plus residue minus weight of beaker,

W = initial weight of pulverized sample = weight of beaker plus sample minus weight of beaker, and

R = resin content of the sample.

NOTE A1.4—The resin content of the sample must be known.

A2. TEST METHOD OF SAMPLING FOR PRESSURE RATING VERIFICATION

A2.1 Scope

A2.1.1 This test method describes the sampling procedure which shall be used in determining the acceptance of a given lot of flanges at the pressure rating specified according to 4.1.4 and Table 1.

A2.2 Sample

A2.2.1 Sample size and selection shall be in accordance with Practice D 1898 except as herein modified.

A2.3 Procedure

A2.3.1 Sample size shall be determined according to Practice D 1898, Appendix X3 and Table X2.1. The Acceptable Quality Level (AQL) shall be 1.50. Inspection Level 1 shall be used in determining the sample size and acceptance constant. A flange set shall be considered to be two samples.

A2.3.2 The specification Limit Value (L) shall be the pressure rating times 4 for burst test qualification and shall be the pressure rating times 1.5 for leak test qualification.

A2.4 Results

A2.4.1 *Acceptance*— If the Quality Level of the sample is greater than or equal to the acceptance constant for both burst and leak testing, the lot shall be accepted at the specified pressure rating category.

A2.4.2 *Rejection*—If the Quality Level is less than the acceptance constant for either burst or leak testing, the lot shall be rejected unless rectification is provided as follows:

A2.4.2.1 The lot shall be resampled at a higher inspection level. The original test results shall be considered a part of the resampled lot. If the lot meets the requirements of A2.4.1 after resampling, the lot shall be accepted at the pressure category specified.

A2.4.2.2 Alternatively, the lot may be derated to a pressure rating that will bring the sample's quality level to a value equal to or greater than the acceptance constant. The lot of flanges shall be reclassified at the lower pressure rating category and appropriately marked according to the designation code in 4.2.

SUMMARY OF CHANGES

Committee D-20 has identified the location of the following changes to this standard since the last issue D4024–94) which may impact the use of this standard.

(1) Changed Note 1 to reference D 5685.
(2) Corrected grammer in 4.1.
(3) Corrected statement construction in 4.2.
(4) Added 7.2 on recycled materials.
(5) Clarified 11.2 on tolerance of operating temperature.
(6) Deleted dualism in key for drawing in 11.4.
(7) Corrected long standing error in bolt torque sequence on 8 hole flange in Fig. 2.
(8) Clarified wording in 12.1.1.
(9) Added Precision and Bias statement.
(10) Corrected references in A2.3.1 to appendix and table which no longer exsisted.
(11) Added this "Summary of Changes" section.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: D 4161 – 01

Standard Specification for "Fiberglass" (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe Joints Using Flexible Elastomeric Seals[1,2]

This standard is issued under the fixed designation D 4161; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers axially unrestrained bell-and-spigot gasket joints including couplings required for machine-made "fiberglass" (glass-fiber-reinforced thermosetting-resin) pipe systems, 8 in. (200 mm) through 144 in. (3700 mm), using flexible elastomeric seals to obtain soundness. The pipe systems may be pressure (typically up to 250 psi) or nonpressure systems for water or for chemicals or gases that are not deleterious to the materials specified in this specification. This specification covers materials, dimensions, test requirements, and methods of test.

1.2 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

NOTE 1—There is a similar but technically different ISO Standard (ISO 8639).

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. Referenced Documents

2.1 *ASTM Standards:*

D 883 Terminology Relating to Plastics[3]

D 1600 Terminology for Abbreviated Terms Relating to Plastics[3]

F 412 Terminology Relating to Plastic Piping Systems[4]

F 477 Specification for Elastomeric Seals (Gaskets) for Joining Plastic Pipe[4]

3. Terminology

3.1 *Definitions:*

3.1.1 *General*—Definitions and abbreviations are in accordance with Terminology D 883 or Terminology F 412, and Terminology D 1600 unless otherwise indicated.

4. Types of Joints

4.1 This specification covers two types of axially unrestrained joints based on effecting soundness of the joint through compression of an elastomeric seal or ring:

4.1.1 Bell-and-spigot or coupling joint with the gasket placed in the bell in circumferential compression. An elastomeric gasket joint design featuring a continuous elastomeric ring gasket placed in an annular space provided in the bell or socket of the pipe or fitting. The spigot end of the pipe or fitting is forced into the bell, thereby compressing the gasket radially to form a positive seal.

4.1.2 Bell-and-spigot or coupling joint with the gasket placed on the spigot in circumferential tension: A push on joint design featuring a continuous elastomeric ring gasket placed in an annular space provided on the spigot end of the pipe or fitting. The spigot is forced into the bell of the pipe or fitting, thereby compressing the gasket radially to form a positive seal.

NOTE 2—A coupling joint of these types is a loose double-bell sleeve used to connect pipes which have spigots at both ends (see Fig. 1). All references to bells in this specification are applicable to the sleeve coupling as well as to the integral bell of a bell-and-spigot gasket joint.

5. Materials and Manufacture

5.1 The gasket shall be a continuous elastomeric ring of circular or other geometric cross section and shall meet the requirements of Specification F 477, unless otherwise specified in this specification. When a splice is used in the manufacture of the gasket, no more than two splices shall be made in any one gasket.

5.1.1 The chemical composition of the gasket shall be compatible with the type of environment to which it will be subjected. Selection of the gasket composition shall be in accordance with a purchaser and seller agreement.

NOTE 3—Consult the gasket manufacturer for advice as to the suitability of specific rubber compounds for the intended service and joint configurations. Items such as cold set when the joint is deflected under low-temperature conditions and maximum and minimum stretch in the gasket may be dependent upon the specific chemical compounds used.

5.2 Materials in the bell and spigot of the joint shall meet the requirements of the applicable ASTM specification for the pipe or fitting of which the joint is a part.

6. Requirements

6.1 *Joint Surfaces*—All surfaces of the joint upon or against

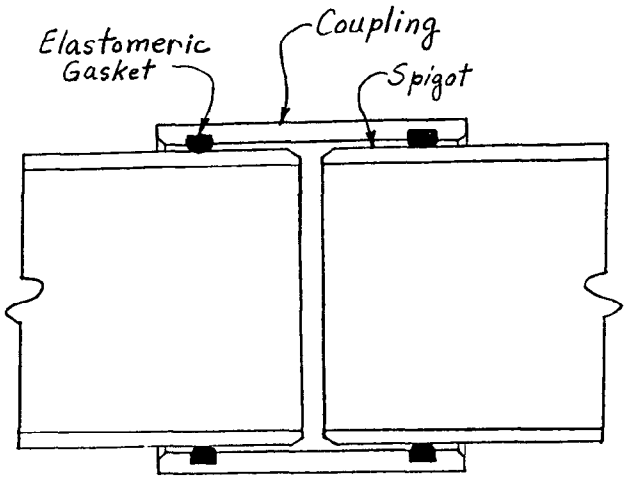

FIG. 1 Typical Coupling Joint Detail

which the gasket may bear shall be smooth and free of cracks, fractures, or other imperfections that would adversely affect the performance of the joint.

6.2 *Joint Geometry*—The design of the joint shall include a means to retain the gasket and prevent it from being unintentionally displaced, either during assembly of the joint or during operation of the completed pipe system.

6.3 *Dimensions and Tolerances*—The provisions of 6.3.1.1 apply only to a joining system utilizing a gasket of circular cross section retained in a rectangular groove. Manufacturers may submit to the purchaser detailed designs for joints utilizing gaskets or grooves, or both, of other geometric shape or for joints not meeting the criteria of 6.3.1. Joints not meeting the requirements of this section shall meet the test requirements of Section 7; such joints shall be acceptable, provided the design is approved by the purchaser prior to manufacture and provided the test pipe complies with the specified test requirements. Test results may be extended to other diameters with the same joint configuration, gasket shape and gasket composition provided substantially similar gasket compressions and gasket hardness are maintained. Gasket dimensions may be increased or decreased provided joint geometry is also appropriately proportioned so that critical relationships like gasket confinement are equal or superior to the tested joint. Design submissions shall include joint geometry, tolerances, gasket characteristics, proposed plant tests, and such other information as required by the purchaser to evaluate the joint design for field performance.

6.3.1 *Joints Using Circular Gasket Cross Sections:*

6.3.1.1 The volume of the annular space provided for the gasket, with the engaged joint at normal joint closure in concentric position, and neglecting ellipticity of the bell and spigot, shall not be less than the design volume of the gasket furnished. For a rectangular gasket groove, the cross-sectional area of annular space shall be calculated for minimum bell inside diameter, maximum spigot outside diameter, minimum width of groove at surface of spigot, and minimum depth of groove. The volume of the annular space shall be calculated at the centerline of the groove and considering the centroid of the cross-sectional area to be at the midpoint between the surface of the groove on which the gasket is seated and the surface of the bell, if the groove is on the spigot, or the surface of the spigot, if the groove is in the bell.

6.3.1.2 When the design volume of the gasket is less than 75 % of the volume of the annular space in which the gasket is confined, the dimensions and tolerances of the gasket, bell, and spigot shall be such that, when the outer surface of the spigot and the inner surface of the bell come into contact at some point in their periphery, the deformation in the gasket shall not exceed 40 % at the point of contact nor be less than 15 % at any point. If the design volume of the gasket is 75 % or more of the volume of the annular space, the deformation of the gasket, as prescribed above, shall not exceed 50 % nor be less than 15 %. The cross-sectional area of annular space shall be calculated for average bell diameter, average spigot diameter, average width of groove at surface of spigot, and average depth of groove. The volume of the annular space shall be calculated at the centerline of the groove and considering the centroid of the cross-sectional area to be at the midpoint between the surface of the groove on which the gasket is seated and the surface of the bell, if the groove is on the spigot, or the surface of the spigot, if the groove is in the bell.

NOTE 4—It is recognized that a relationship exists between the watertightness of a joint, the gasket deformation, and the ratio of gasket volume to space volume. For high-pressure applications, it may be necessary to provide a very high-volume ratio to obtain a sound joint. Some manufacturers also have developed satisfactory joints with very little gasket deformation, but meet the requirements of Section 6 by utilizing a very high-volume ratio.

6.3.1.3 When determining the maximum percent deformation of the gasket, the minimum depth of groove and the stretched gasket diameter shall be used and calculations made at the centerline of the groove. When determining the minimum percent deformation of the gasket, the maximum bell diameter, the minimum spigot diameter, the maximum depth of groove, and the stretched gasket diameter shall be used and calculations made at the centerline of the groove. For gasket deformation calculations, if the gasket is placed on the spigot in circumferential tension, the stretched gasket diameter shall be determined as being the design diameter of the gasket divided by the square root of $(1 + x)$ where x equals the design percent of gasket stretch divided by 100. If the gasket is placed in the bell in circumferential compression, the design diameter of the gasket shall be used.

6.3.1.4 The taper on all sealing surfaces of the bell and spigot on which the elastomeric gasket may bear after closure of the joint and at any degree of partial closure, except within the gasket groove, shall form an angle of not more than 2° with the longitudinal axis of the pipe. If the joint design does not incorporate a mechanical locking feature, the joint shall be designed and manufactured in such a way that at the position of normal joint closure, the parallel surfaces upon which the gasket may bear after closure will extend not less than 0.75 in. (20 mm) away from the edges of the gasket groove.

6.3.1.5 *Circular Gaskets*:

6.3.1.5.1 In a joint in which the gasket is placed in the bell in circumferential compression, the circumferential length of the gasket shall be such that, when inserted into the gasket groove, the amount of circumferential compression will be less than 4 %. In larger pipe diameters, an adhesive may be required to hold the gasket in place prior to installation.

Copyright by the ASTM International
Wed Feb 02 02:02:14 2005

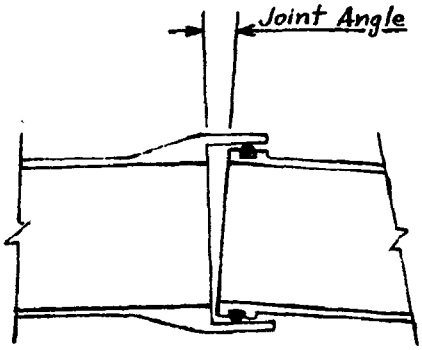
6.3.1.5.2 In an elastomeric joint in which the gasket is placed on the spigot in circumferential tension, the circumferential length of the gasket shall be such that, when installed in the gasket groove, the amount of stretch shall not exceed 30 %.

6.3.1.5.3 Compute the amount of compression or stretch by comparing the circumferential length of the centroid of the relaxed gasket with the circumferential length of the centroid of the compressed or stretched gasket after installation in the bell or on the spigot.

6.3.1.5.4 Each gasket shall be manufactured to provide the volume of elastomer required by the pipe manufacturer's joint design, with a tolerance of ±1 % for gaskets of 1.0-in. (25-mm) diameter and larger. The allowable percentage tolerance shall vary linearly between ±3 % and ±1 % for gasket diameters between 0.5 and 1.0 in. (13 and 25 mm).

6.3.2 The tolerances permitted in the construction of the joint shall be those stated in the pipe manufacturer's design as approved.

6.3.3 *Drawings*—The manufacturer shall furnish drawings of the joint and gasket, including dimensions and tolerances, if requested by the purchaser.



Pipe Size	Joint Angle
≤ 20 in.	3°
>20 in. ≤ 33 in.	2°
>33 in. ≤ 60 in.	1°
> 60 in.	½°

NOTE 1—Joint opening shall not exceed the maximum unstressed limit permitted by dimensional clearance between spigot and bell.

FIG. 2 Typical Bell-and-Spigot Gasket Joint Detail

7. Laboratory Performance Requirements

7.1 *General*:

7.1.1 The gasket shall be the sole element depended upon to make the joint leakproof. The assembled joints shall pass the performance tests listed in this section. The tests shall be performed with components selected to provide minimum compression in the gasket. The internal hydrostatic pressures required in 7.2 and 7.3 shall be two times the rated pressure, if the pipe is manufactured for pressure service, or 29 psi (200 kPa), if the pipe is manufactured for nonpressure service.

7.1.2 Laboratory hydrostatic pressure tests on joints shall be made on an assembly of two sections of pipe properly connected in accordance with the joint design. Suitable bulkheads may be provided within the pipe adjacent to and on either side of the joint, or the outer ends of the two jointed pipe sections may be bulkheaded. Restraints may be provided at the joint to resist transverse thrust. No coatings, fillings, or packings shall be placed prior to the hydrostatic tests.

7.2 *Pipes in Angularly Deflected Position*—Using a pipe and joint system as described in 7.1.2, the test sections shall be deflected angularly, as shown in Fig. 2, and subjected to the appropriate internal hydrostatic test pressure for 10 min without leakage. The angle defined by the joint openings given in Fig. 2 is the angle between the axis of the two joined pipes.

7.2.1 Joints intended for use of pressures greater than 250 psi may have lower allowable angular deflections than those given in Fig. 2 by manufacturer purchaser agreement. The joints shall be tested at the manufacturers maximum allowed angular deflection.

7.2.2 Determine the joint opening by scribing a circumferential index mark on the outside of the pipe a sufficient distance from the spigot end to be visible when the pipe is joined. Measure the maximum and minimum distance from the end of the bell to the mark. The difference equals the joint opening. Fig. 2 illustrates a typical joint in closed and deflected positions and the index mark.

NOTE 5—This test is a laboratory performance test of joint integrity and is not indicative of allowable angular deflections in field installations. In actual installations, deflections greater than the manufacturer's recommended maximum should be avoided, and elbows, bends, or special fittings should be used in such cases.

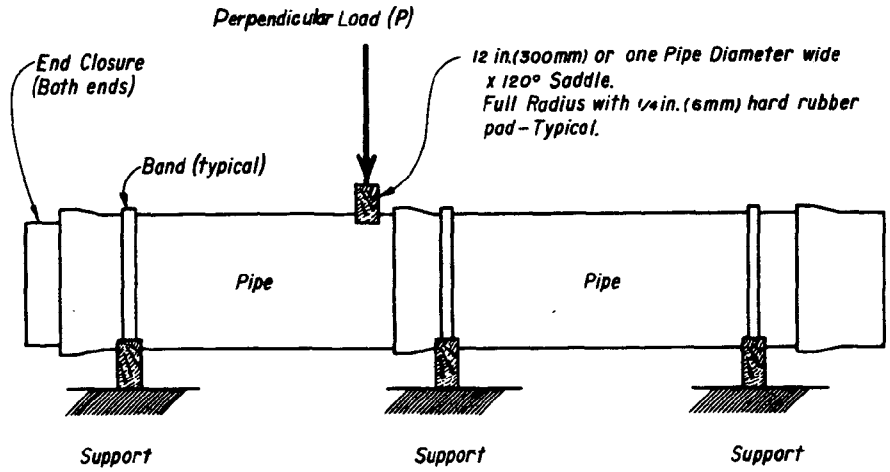
7.3 *Pipes in Laterally Offset Position (Shear Loading)*—Using a pipe and joint system as described in 7.1.2, the test sections shall be deflected while the pipe units are in a horizontal position, as shown in Fig. 3, by applying a perpendicular load. The load shall be 100 lb/in. (17.5 kN/m) in diameter. The load shall be uniformly applied over an arc of not more than 120° along a longitudinal distance equal to one pipe diameter or 12 in. (300 mm), whichever is the smaller, at the unsupported spigot end of the pipe immediately adjacent to the bell of the assembled joint. The pipe in the test shall be supported on adequate blocks placed immediately behind or on the bells, as indicated in Fig. 3. Bands may be required to secure the pipe to the blocks. There shall be no leakage when the appropriate internal hydrostatic test pressure is applied for 10 min after application of the load.

7.4 *Vacuum or External Pressure Test*—The assembled joint shall withstand an external pressure of 11.6-psi (80-kPa) gage or an internal vacuum of −11.6-psi (−80-kPa) gage while in the angularly deflected position, as in 7.2, and in the laterally offset position, as in 7.3. Allow the pressure to stabilize for 30 min, then seal off for a minimum of 10 min. The maximum permissible pressure increase inside of the pipe during the seal-off period shall be 0.1 psi (0.7 kPa). Some grades of pipe may not have the capability in the pipe wall of withstanding the above vacuum or external pressure. In such cases, the joint design may be considered as meeting these criteria if a pipe and joint system, incorporating a geometrically identical joint and heavier-walled pipe, meets the criteria satisfactorily.

8. Retesting

8.1 If any failure occurs during performance of the tests specified in Section 7, the joint may be retested to establish

Copyright by the ASTM International
Wed Feb 02 02:02:15 2005



NOTE 1—The load shall be applied perpendicular to the axis of the pipe. It may be applied vertically, as shown in this figure, or at any other circumferential orientation.

FIG. 3 Shear Loading-Test Setup

conformity in accordance with agreement between the purchaser and the manufacturer.

9. Keywords

9.1 angular deflection; bell and spigot; coupling; elastomeric seals; flexible gasket; glass-fiber-reinforced; pipe joints; specification; thermosetting resin

SUMMARY OF CHANGES

Committee D20 has identified the location of selected changes to this standards since the last issue (D 4161–96) that may impact the use of this standard.

(1) Modified ISO equivalence statement.
(2) Revised numbering of 6.3 to clarify. (Only applies to circular gaskets.)
(3) Added 7.2.1 relating to high pressure points.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Designation: E 814 – 00

An American National Standard

Standard Test Method for Fire Tests of Through-Penetration Fire Stops[1]

This standard is issued under the fixed designation E 814; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

INTRODUCTION

Characteristically fire spreads from one building compartment to another by the collapse of a barrier, or by openings through which flames or hot gases may pass, or by transfer of sufficient heat to ignite combustibles beyond the barrier. Test Methods E 119 describe the method to be used to measure the fire-resistive performance of these barriers.

However, various techniques of providing for the distribution of services within a structure sometimes require that openings be made in fire-resistive walls and floors to allow the passage of such penetrating items as cables, conduits, pipes, trays, and ducts through to the adjacent compartment. Fire-stop material is installed into these openings to resist the spread of fire.

The performance of through-penetration fire stops should be measured and specified according to a common standard that describes the method of fire exposure and rating criteria.

1. Scope

1.1 This test method is applicable to through-penetration fire stops of various materials and construction. Fire stops are intended for use in openings in fire-resistive walls and floors that are evaluated in accordance with Test Methods E 119.

1.2 Tests conducted in conformance with this test method record fire-stop performance during the test exposure; but such tests shall not be construed to determine suitability of the fire stop for use after test exposure.

1.3 This test method also measures the resistance of fire stops to an external force stimulated by a hose stream. However, this test method shall not be construed as determining the performance of the fire stop during actual fire conditions when subjected to forces such as failure of cable support systems and falling debris.

1.4 The intent of this test method is to develop data to assist others in determining the suitability of the fire stops for use where fire resistance is required.

1.5 *This standard is used to measure and describe the response of materials, products, or assemblies to heat and flame under controlled conditions, but does not by itself incorporate all factors required for fire-hazard or fire-risk assessment of materials, products, or assemblies under actual fire conditions.*

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.7 The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered requirements of the standard.

2. Referenced Documents

2.1 *ASTM Standards:*

E 119 Test Methods for Fire Tests of Building Construction and Materials[2]

3. Terminology

3.1 *Definition:*

3.1.1 *fire stop*—a through-penetration fire stop is a specific construction consisting of the materials that fill the opening around penetrating items such as cables, cable trays, conduits, ducts, and pipes and their means of support through the wall or floor opening to prevent spread of fire.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *test specimen*—the fire stop being tested.

3.2.2 *test assembly*—the wall or floor into which the test specimen(s) is (are) mounted or installed.

4. Summary of Test Method

4.1 This method of testing through-penetration fire stops exposes fire stops to a standard temperature-time fire, and to a subsequent application of a hose stream.

4.2 Ratings are established on the basis of the period of resistance to the fire exposure, prior to the first development of through openings, flaming on the unexposed surface, limiting

[1] This method is under the jurisdiction of Committee E05 on Fire Standards and is the direct responsibility of Subcommittee E05.11 on Construction Assemblies.

Current edition approved Aug. 10, 2000. Published October 2000. Originally published as E 814 – 81. Last previous edition E 814 – 97.

[2] *Annual Book of ASTM Standards*, Vol 04.07.

Copyright by the ASTM International
Wed Feb 02 02:02:40 2005

thermal transmission criterion, and acceptable performance under application of a hose stream.

5. Significance and Use

5.1 This test method is used to determine the performance of a fire stop with respect to exposure to a standard time-temperature fire test and a hose stream test. The performance of a fire stop is dependent upon the specific assembly of materials tested including the number, type, and size of penetrations and the floors or walls in which it is installed.

5.2 Two ratings are established for each fire stop. An *F* rating is based upon flame occurrence on the unexposed surface, while the *T* rating is based upon the temperature rise as well as flame occurrence on the unexposed side of the fire stop. These ratings, together with detailed performance data such as the location of through-openings and temperatures of penetrating items are intended to be one factor in assessing performance of fire stops.

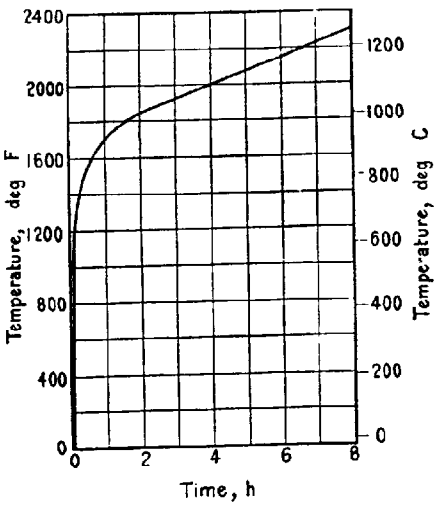
6. Control of Fire Tests

6.1 *Time-Temperature Curve*—The fire environment within the furnace shall be in accordance with the standard time-temperature curve shown in Fig. 1. The points on the curve that determine its character are:

Ambient at 0 min
1000°F (538°C) at 5 min
1300°F (704°C) at 10 min
1550°F (843°C) at 30 min
1700°F (927°C) at 60 min
1850°F (1010°C) at 120 min
2000°F (1093°C) at 240 min
2300°F (1260°C) at 480 min or over

6.2 *Furnace Temperatures*:

6.2.1 The temperature fixed by the curve shall be the average temperature obtained from the readings of thermocouples symmetrically disposed and distributed within the test furnace to show the temperature near all parts of the assembly.



NOTE—For a closer definition of the temperature-time curve, see Annex A1.

FIG. 1 Temperature-Time Curve

Use a minimum of three thermocouples, with not fewer than five thermocouples per 100 ft^2 (9.29 m^2) of floor surface, and not fewer than nine thermocouples per 100 ft^2 of wall specimen surface.

6.2.2 Enclose the thermocouples in sealed protection tubes of such materials and dimensions that the time constant of the protected thermocouple assembly lies within the range (see Note 1) from 300 to 400 s. The exposed length of the pyrometer tube and thermocouple in the furnace chamber shall be not less than 12 in. (300 mm). Use of other types of protection tubes or pyrometers is acceptable provided that temperature measurements obtained in accordance with Fig. 1 are within the limit of accuracy that applies for furnace temperature measurements.

NOTE 1—A typical thermocouple meeting these time-constant requirements may be fabricated by fusion-welding the twisted ends of No. 18 B and S gage (0.040 in.) (1.02 mm) Chromel-Alumel wires, mounting the leads in porcelain insulators and inserting the assembly so the thermocouple bead is 0.50 in. (13 mm) from the sealed end of a standard weight, nominal ½-in. iron, steel, or Inconel pipe. (Inconel is a trademark of Inco Alloys, Inc., 3800 Riverside Dr., P.O. Box 1958, Huntington, WV 25720.) The time constant for this and for several other thermocouple assemblies was measured in 1976. The time constant may also be calculated from knowledge of its physical and thermal properties. See Research Report RR:E05-1001, available from ASTM Headquarters.

6.2.3 For floors, place the junction of the thermocouples 12 in. (300 mm) away from the exposed face of the assembly. In the case of walls, place the thermocouples 6.0 in. (150 mm) away from the exposed face.

6.2.4 Read the temperature at intervals not exceeding 5 min during the first 120 min. Thereafter, the intervals shall not exceed 10 min.

6.2.5 The accuracy of the furnace control shall be such that the area under the temperature-time curve, obtained by averaging the results from the pyrometer or thermoelectric device readings, is within 10 % of the corresponding area under the standard temperature-time curve shown in Fig. 1 for fire tests of 60 min or less duration; within 7.5 % for those over 60 min and not more than 120 min; and within 5 % for tests exceeding 120 min in duration.

6.3 *Unexposed Surface Temperatures*:

6.3.1 Make at least one measurement at each of the following locations on the unexposed surface of the test sample and floor or wall assembly as shown in Fig. 2.

6.3.2 Additional temperature measurements are made at the discretion of the testing agency to obtain representative information on the performance of the fire stops.

6.3.3 Measure temperatures on the surface of the fire stop and assembly with thermocouples placed under flexible pads specified in Annex A2. The pads shall be held firmly against the surface and shall fit closely about the thermocouples. The thermocouple junction shall be located under the center of the pads. The thermocouple leads under the pads shall be not heavier than No. 18 B and S gage (0.040 in.) (1.02 mm) and shall be electrically insulated with heat-resistant moisture-resistant coverings.

6.3.4 Measure temperatures of each type and size of penetrating item with at least one thermocouple located 1.0 in. (25.4 mm) from the unexposed surface of the fire-stop material.

Floor Assembly-Plan View
Wall Assembly-Elevation View

Floor Assembly-Elevation View
Wall Assembly-Plan View

Legend:

A—At a point on the surface of the fire stop 1 in. (25 mm) from one through-penetrating item for each type of penetrating item employed in the field of the fire stop. If the grouping of penetrating items through the test sample prohibits placement of the thermocouple pad, the thermocouple shall not be required.

B—At a point on the fire stop surface at the periphery of the fire stop.

C—At a minimum of three points on the fire stop surface approximately equidistant from a penetrating item or group of penetrating items in the field of the fire stop and the periphery.

D—At one point on any frame that is installed about the perimeter of the opening.

E—At one point on the unexposed surface of the wall or floor that is a minimum of 12 in. (305 mm) from any opening.

F—At one point on each type of through-penetrating item. If the through-penetrating item is insulated or coated on the unexposed side, the thermocouple shall be located on the exterior surface of the insulation or coating. If the coating or insulation does not extend the full length of the penetrating item on the unexposed side, an additional thermocouple shall be installed on the penetrating item 1.0 in. (25.4 mm) beyond the termination of the insulation or coating.

FIG. 2 Temperature Measurement Locations

The thermocouple bead shall be held firmly against the penetrating item. The thermocouple leads shall not be heavier than No. 22 B and S gage (0.025 in.) (0.635 mm) and shall be electrically insulated with heat-resistant and moisture-resistant coverings. The pads as described above shall be held firmly against the penetrating item and shall fit closely about the thermocouples.

6.3.5 Temperature readings shall be taken at intervals not exceeding 15 min until a reading exceeding 212°F (100°C) has been obtained at any one point. Thereafter, at the discretion of the testing body, the readings shall be taken more frequently, but the intervals need not be less than 5 min.

6.4 *Differential Pressure*:

6.4.1 The pressure differential between the exposed and unexposed surfaces of the test assembly, as defined in 3.2.2, shall be measured at two points 0.78 in. (20 mm) from the exposed surface of the test assembly as follows:

6.4.1.1 *Walls*—At two points along the vertical center line. The two points shall be separated by a vertical distance that is equal to or greater than one-half of the height of the test assembly.

6.4.1.2 *Floors*—At approximately the quarter points along the longitudinal center line.

6.4.2 The pressure-measuring probes shall be a Tee-shaped probe or a tube probe and shall be manufactured from stainless steel or other suitable material.

6.4.3 Measure the pressure by means of a manometer or equivalent transducer. The manometer or transducer shall be capable of reading 0.01-in. H_2O (2.5-Pa) increments with a measurement precision of 0.005 in. H_2O (1.25 Pa).

6.4.4 The furnace shall be controlled such that the differential pressure between the exposed and the unexposed surfaces of the test assembly complies with either 6.4.4.1 or 6.4.4.2.

6.4.4.1 *Standard Pressure Condition*—Except for the first 10 min. of the test, the furnace pressure shall be at least 0.01 in. wg (2.5 Pa) greater than the pressure on the unexposed side of the test assembly at the following locations:

(1) Walls—At the lowest elevation of the test specimen (see Note 2).

(2) Floors—At the location of the pressure-measuring probes.

NOTE 2—A supplementary pressure probe, in addition to the two probes specified in 6.4.1.1, may be used to determine compliance with this requirement.

6.4.4.2 *Unique Pressure Condition*—The differential pressure shall be specified by the test sponsor. The furnace shall be controlled such that the specified differential pressure is maintained throughout the duration of the test, excluding the first 10 min., within 20 % of the specified pressure.

7. Test Specimen

7.1 *Construction and Size*:

7.1.1 The construction of the test fire stops shall be of sufficient size and include all conduits, pipes, cables (jacket types, sizes, conductor types, percent fills), required supports, or other through-penetrating items so as to produce a representative fire stop for which evaluation is being sought. Install and test fire stops in each construction type for which ratings are being sought.

7.1.2 Install through-penetrating items so that they extend

Copyright by the ASTM International
Wed Feb 02 02:02:56 2005

12 in. (300 mm) on the exposed side and 36 in. (900 mm) on the unexposed side unless either or both of these extensions are not typical of actual field installations. In such cases, the installation shall be representative of actual field installations. Support the extended portion of through-penetrating items on the unexposed side so as to minimize relative movement between the through-penetrating item and the restraining frame in which the test assembly is mounted. Cap or otherwise seal the individual ends of through-penetrating items on the exposed side. When the through-penetrating item is a closed system that in actual field practice is not vented or open to the atmosphere, the through-penetrating item shall be capped or sealed on the unexposed side. In such cases, a pressure relief hole shall be provided through the cap or seal on the unexposed side. Otherwise, through-penetrating items shall not be capped or sealed on the unexposed side.

7.1.3 The periphery of the fire stop shall not be closer than 1½ times the thickness of the test assembly or a minimum of 12 in. (300 mm) to the furnace edge, whichever is greater (see Note 3).

NOTE 3—The distance between fire stop periphery and furnace edge may be reduced if the testing agency demonstrates and reports that the edge effects do not affect the results.

8. Protection and Conditioning

8.1 Prior to fire test, condition the floor or wall assembly and fire stops to provide, a moisture condition representative of that existing in similar construction in buildings. For the purposes of standardization, this condition is established at equilibrium resulting from drying in an ambient atmosphere of 50 % relative humidity at 73°F (23°C). However, with some assemblies and fire stops it is difficult or impossible to achieve such uniformity. Therefore, floor or wall assemblies and fire stops are eligible for testing when their dampest portion has achieved a moisture content corresponding to drying to equilibrium with air in the range from 50 to 75 % relative humidity at 73 ± 5°C (23 ± 3°C). If the assembly or fire stops dried in a heated building fail to meet these requirements after a 12-month conditioning period, or if the nature of the construction is such that drying of the assembly or fire stop interior will be prevented by hermetic sealing, these requirements are waived, except as to attainment of the required strength as described in 9.1, and the assembly or fire stop is tested in the condition in which it then exists.

NOTE 4—A method for determining the relative humidity within a hardened concrete specimen with electric sensing elements is described in Appendix I of a paper by C.A. Manzel, "A Method for Determining the Moisture Condition of Hardened Concrete in Terms of Relative Humidity," *Proceedings*, ASTM, Vol 55, 1955, p. 1083. A similar procedure with electric sensing elements can be used to determine the relative humidity within fire test assemblies and fire stops made with other materials.

8.2 Protect the testing equipment, specimen, and assembly undergoing the fire test from any condition of wind or weather that is capable of leading to abnormal results. The ambient air temperature at the beginning of the test shall be within the range from 50 to 90°F (10 to 32°C). The velocity of air across the unexposed surface measured just before the test begins shall not exceed 4.4 ft/s (1.3 m/s) as determined by an anemometer placed at right angles to the unexposed surface. If mechanical ventilation is employed during the test, do not direct an air stream across the surface of the specimen.

9. Conduct of Tests

9.1 *Time of Testing*—Do not test the test specimen until the test assembly has developed sufficient strength to retain the fire stops securely in position.

9.2 *Fire Test*—Continue the test until the evaluation period being sought is reached or until the rating criteria of Section 10 are satisfied.

9.3 *Hose Stream Test*:

9.3.1 Subject a duplicate specimen to a fire-exposure test for a period equal to one half of that indicated as the resistance period in the fire test, but not more than 60 min, immediately after which subject the specimen to the impact, erosion, and cooling effects of a hose stream as described in Table 1 directed first at the middle and then at all parts of the exposed face, with changes in direction being made slowly.

9.3.2 When requested by the test sponsor, and with the advice and consent of the testing body, the hose stream test shall be made on the specimen subjected to the fire test immediately following the fire test.

9.3.3 Deliver the stream through a 2½-in. (63.5-mm) hose and discharge through a National Standard playpipe of corresponding size equipped with a 1⅛-in. discharge tip of the standard-taper, smooth-bore pattern without a shoulder at the orifice. The water pressure and duration of application shall be as specified in Table 1.

9.3.4 The nozzle orifice shall be 20 ft (6.1 m) from the center of the exposed surface of the test specimen if the nozzle is so located that, when directed at the center, its axis is normal to the surface of the test specimen. If otherwise located, its distance from the center shall be less than 20 ft (6.1 m) by an amount equal to 1 ft (300 mm) for each 10° of deviation from the normal.

10. Rating Criteria

10.1 *F Rating*:

10.1.1 A fire stop shall have met the requirements for the *F* rating when it remains in the opening during the fire test and hose stream test and the following conditions are met.

10.1.2 The fire stops shall have withstood the fire test for the rating period by preventing the passage of flame through openings, or the occurrence of flaming on any element of the unexposed side of the fire stops.

TABLE 1 Pressure and Duration—Hose Stream Test[A]

Resistance Period	Water Pressure at Base of Nozzle, psi (kPa)	Duration of Application, s/ft²(m²) of Exposed Area
240 min and over if less than 480 min	45 (310)	3.0 (32)
120 min and over if less than 240 min	30 (210)	1.5 (16)
90 min and over if less than 120 min	30 (210)	0.90 (10)
60 min and over if less than 90 min	30 (210)	0.60 (6)
Less than 60 min if desired	30 (210)	0.60 (6)

[A]When a single fire stop is tested, calculation of the area to be exposed to the hose stream may include more than the outside dimensions of the fire stop if the hose stream uniformly traverses that area. Where multiple test fire stops are tested in the same wall or floor assembly, the rectangular area encompassing all of the fire stops shall be considered as the exposed area since the hose stream must traverse this calculated area during its application.

Copyright by the ASTM International
Wed Feb 02 02:02:56 2005

10.1.3 During the hose stream test, the fire stop shall not develop any opening that allows a projection of water from the stream beyond the unexposed side.

10.2 *T Rating*:

10.2.1 A fire stop shall have met the requirements for the *T* rating when it remains in the opening during the fire test and hose stream test and the following conditions are met.

10.2.1.1 The transmission of heat through the fire stops during the rating period shall not have been such as to raise the temperature of any thermocouple on the unexposed surface of the fire stop or on any penetrating item more than 325°F (181°C) above its initial temperature. Also, the fire stops shall have withstood the fire test during the rating period by preventing the passage of flame through openings, or the occurrence of flaming on any element of the unexposed side of the fire stops.

10.2.1.2 During the hose stream test, the fire stop shall not develop any opening that allows a projection of water from the stream beyond the unexposed side.

11. Report

11.1 Report results in accordance with the performance in the tests prescribed in this test method. Express the results in time periods of resistance to passage of flame to the nearest integral minute. Reports shall include the following:

11.1.1 Description of the assembly and materials; identify and describe penetrating items of the test fire stop. Drawings depicting geometry, exact size (length, width, thickness), and location of fire stops within the test assembly.

11.1.2 The relative humidities of the test assembly and fire stop materials, if applicable.

11.1.3 The furnace and the unexposed side temperatures for the duration of the standard fire test.

11.1.4 The *F* and *T* ratings for each fire stop in the time period of resistance.

11.1.5 The location of pressure probes and the differential pressures between the exposed and unexposed surfaces of the test assembly measured during the fire test. When the test is conducted with a unique pressure condition in accordance with 6.4.4.2, the report shall state the basis for the specified pressure.

11.1.6 Record observations of significant details of the behavior of the fire stops during the test and after the furnace fire is extinguished. These shall include cracks, deformation, flaming, and smoke issuance. Also, these include continued burning within the fire stop after termination of the fire test.

11.2 When the indicated fire stop rating period is 60 min or over, a correction shall be applied for variation of the furnace exposure from the prescribed, where it will affect the rating, by multiplying the indicated period by two thirds of the difference in area between the curve of average furnace temperature and the standard curve for the first three fourths of the period and dividing the product by the area between the standard curve above a base line of 68°F (20°C) for the same part of the indicated period, the latter area increased by 54°F·h or 30°C·h (3240°F·min or 1800°C·min), to compensate for the thermal lag of the furnace thermocouples during the first part of the test. For fire exposure in the test higher than standard, the indicated rating period shall be increased by the amount of the correction and be similarly decreased for fire exposure below surface. The correction is expressed as follows:

$$C = \frac{2I(A - A_s)}{3(A_s + L)} \quad (1)$$

where:

C = correction in the same units as I,
I = indicated fire-resistance period,
A = area under the curve of indicated average furnace temperature for the first three fourths of the indicated period,
A_s = area under the standard furnace curve for the same part of the indicated period, and
L = lag correction in the same units as A and A_s(54°F·h or 30°C·h; 3240°F·min or 1782°C·min).

12. Precision and Bias

12.1 The precision and bias of this test method have not been determined.

A2. REQUIREMENTS FOR THERMOCOUPLE PADS

A2.1 The pads used in measurements of temperature of unexposed surfaces of specimens shall be of suitable inorganic material and shall exhibit the following properties:

A2.1.1 *Length and Width*—2.00 ± 0.04 in. (50.8 ± 1 mm).

A2.1.2 *Thickness*—0.40± 0.05 in. (10 ± 1 mm).

A2.1.3 *Density*—31.2± 0.6 lb/ft^3 (500 ± 10 kg/m^3).

A2.1.4 *Thermal Conductivity at 150°F*—0.380 ± 0.027 Btu·in./h·ft^2·°F (0.055 ± 0.003 W/m·K).

A2.2 The pads shall be capable of being shaped without breaking. The complete pad shall contact the surface against which it is placed.

APPENDIX

(Nonmandatory Information)

X1. DISCUSSION OF SEVERAL ITEMS IN THIS TEST METHOD

X1.1 Introduction

X1.1.1 In writing this standard, various comments and engineering points of view were considered. This test method was written to reflect the broadest possible consensus of these comments.

X1.1.2 This appendix provides a brief discussion of several significant items that were considered. It is intended that the basis for the items included in this test method as well as conflicting points of view, be presented in this discussion.

X1.2 Applicability

X1.2.1 This test method is applicable to through-penetration fire stops of various materials and construction. These fire stops are intended for use in openings in fire resistive walls and floors.

X1.2.2 This test method does not apply to termination devices intended to provide electrical, communication, or other circuitry at the surface of the assembly, and which are evaluated as an integral part of an assembly in accordance with Test Methods E 119.

X1.3 Criteria

X1.3.1 *General*—This fire test method for fire stops is intended to be concerned with evaluating protection provided for openings created in walls or floors that otherwise have a fire resistance rating established in accordance with Test Methods E 119. Presently fire doors and windows, which are similar items, are evaluated by other ASTM standards. Accordingly, the objective of this test method is to assure that the use of such fire stops would not jeopardize the required fire resistance performance of the wall or floor assembly. The rating criteria are accordingly predicated on those conditions relevant to ratings of walls and floors by Test Methods E 119, modified to the extent necessary to take cognizance of the special conditions represented by the occurrence of the fire stops including the penetrating items. In Test Methods E 119, conditions of acceptance include (*1*) passage of flame and hot gases, (*2*) unexposed surface temperature rise, (*3*) ignition of cotton waste, and (*4*) hose stream.

X1.3.2 *Passage of Flame and Hot Gases and Ignition of Cotton Waste*—In Test Methods E 119 one criterion of acceptance of a floor-ceiling or wall is that the assembly shall have withstood the fire endurance test without passage of flame or gases hot enough to ignite cotton waste. The object of this criterion is to minimize the potential for igniting combustible material that might be placed in contact with the unexposed surface. In this test method, the use of cotton waste is excluded and the judgment shall be based only upon visual observation and surface temperatures.

X1.3.3 In Test Methods E 119, visual observation of the passage of flames and hot gases is supplemented with the use of cotton waste. The cotton waste serves as an additional indicator where visual observations are insufficient to determine whether passage of hot gases is occurring. In this test method the cotton waste criterion was excluded for the following reasons: (*1*) the through-penetrating items of a fire stop that continue beyond the wall or floor surface often constitute the combustibles at the unexposed surface, while at the same time minimize the opportunity for other combustibles to come in contact with the wall or floor at the vicinity of the penetration and (2) the through-penetrating items may be of a nature that they inhibit placement of the cotton waste on the protection material surface, while at the same time often being of sufficient temperature that contact with the cotton waste would ignite the cotton waste, thus giving a false indication of fire stop surface ignition.

X1.3.4 *Unexposed Surface Temperatures*—It has been argued that temperatures on the unexposed surface should not be considered in determining the performance of the fire stops, since the fire stops will be installed in such places where they will not be in contact with wood, carpeting, plastic, or other such materials which may ignite at relatively low temperatures. It is further argued a temperature limitation should not be imposed on frames about the opening of fire stop devices or systems since they represent a direct path for heat to flow through to the unexposed surface.

X1.3.5 While these arguments may be valid for some installations, it will be true that the fire stop devices will also be used in areas where they will come in contact with wood, dust, carpeting, paint, wall coverings, or other such materials.

X1.3.6 Further, there are cases where rigorous regulations prohibit combustibles, other than the material that passes

Copyright by the ASTM International
Wed Feb 02 02:02:57 2005

through the wall or floor, from the area in which the fire stops are located. However, the record clearly establishes that combustible materials such as dust accumulation, workman's clothing items, and miscellaneous building and repair items may well be found in such locations.

X1.3.7 It has been argued that the use of temperature limitation as described in Test Methods E 119 must be retained if the overall character of the fire-resistance rating is to be retained.

X1.3.8 In order to satisfy both positions this test method provides two ratings: a *T* rating incorporating temperature and flame limitation, and an *F* rating predicated only on observation of passage of flame or hot gases.

X1.3.9 The *F* rating is based upon observation of passage of flame. The *T* rating is based upon passage of flame and a maximum individual temperature limitation of 325°F (181°C) above ambient. Therefore, depending upon the construction, the authority having jurisdiction may choose the rating that is most appropriate to fulfill the particular needs of the building.

X1.3.10 Placement of thermocouples as specified by the test method is predicated on obtaining temperatures representative of the various fire-stop items, and the difference in heat transmission through the fire-stop material at various locations.

X1.3.11 A location of approximately 1.0 in. (25 mm) from a penetrating item on the unexposed surface of the fire stop would represent a hot point on fire-stop surface. The distance of 1.0 in. (25 mm) was obtained since one size of standard thermocouple pads is 2.0 by 2.0 in. (50 by 50 mm), and the thermocouple junctions shall be at the center of the pad. This fixes 1.0 in. (25 mm) as the closest permitted spacing from penetrating items.

X1.3.12 A location at a point on the surface at the periphery of the fire-stop material, and at a point approximately equidistant from penetrating items in the field of the fire stop and the periphery would obtain temperature information helpful in evaluating the thermal transmission through the fire stop.

X1.3.13 Also, temperatures of any frame about the opening and the temperatures of penetrating items (that is, cable conductor, conduit) shall be recorded in evaluating the thermal transmission performance of the fire stop.

X1.3.14 The test method indicates that the use of additional thermocouples may be required as determined for individual fire stops.

X1.3.15 *Hose Stream Test*—Passage of the hose stream test was included as an acceptance criterion since it is an indicator of the integrity of the fire stop during fire exposure and the overall reliability of the material to perform its intended function. The hose stream test method as outlined in Test Methods E 119 is considered as applicable to the fire stops.

X1.3.16 Not to conduct a hose stream test without applying any design live load to the test assemblies, would be fire testing the assemblies while ignoring their integrity. It is important that an indication of the integrity of performance be obtained for the fire stops. Failure of the integrity of the fire stops would aid the spread of fire by causing passages for the flames and hot gases.

X1.3.17 However, it was argued that conducting the hose stream test may be difficult to perform at various testing facilities without significant modifications to equipment.

X1.3.18 It was proposed that the hose stream test be included as an option only. Also, it was argued that different hose streams (pressure, spray, durations) be included as an option.

X1.3.19 Although the hose stream tests provide a measure of the structural performance of the fire stop material, it should not be construed as a measure of the load carrying ability of the fire stop tested.

X1.3.20 Also, the hose stream test is not intended to evaluate the structural performance of the floor or wall after the inclusion of the various fire stops.

X1.4 Test Specimen

X1.4.1 The cables, conduits, pipes and other penetrating items used in the fire stops shall be representative of the fire stop for which evaluation is desired. It is intended that the data and information provided by the testing of the fire stops with various penetrating items would be used to determine acceptability of a specific fire stop in the construction.

X1.4.2 Through-penetrating items, as contemplated by this test method, generally represent a small portion of a much larger mechanical, electrical, or similar system. Since this test method is intended to focus on the performance of firestops, standard support and capping provisions are defined for through-penetrating items. Users are cautioned that these standard support and capping provisions are not necessarily representative of field installations nor do they represent worst-case conditions. At the scale contemplated by this test method, it is not feasible to simulate or evaluate all of the performance characteristics associated with these systems that may effect a penetration through a fire-resistive wall or floor. For example, in an actual building fire, significant relative movement may occur between a through-penetrating item and a fire-resistive floor or wall. This test method specifies that, in general, through-penetrating items be supported on the unexposed side by brackets that are attached to the frame in which the test assembly is mounted. Thus, some relative moment may occur due to the deflection of the test assembly. This relative movement is not, however, indicative of that which may occur in actual field installations due to the limited span of the test assembly and other factors. Furthermore, the extension or termination, or both, of these systems will vary considerably. This test method requires that, in general, through-penetrating items be capped or otherwise sealed on the exposed side. This test method also specifies that cables, conduits, pipes, and other through-penetrating items extend 12 in. (300 mm) into the furnace chamber and 36 in. (900 mm) beyond the unexposed surface. From a heat transfer standpoint, previous testing has shown that this arrangement satisfactorily represents continuous cables and conduit as would be encountered in the field. Exceptions for different support and termination conditions have been included for through-penetrating items that will not extend significantly beyond the test assembly in actual field installations. With respect to capping or sealing, an exception has been included for through-penetrating items that will not normally be open to the atmosphere in field installations.

X1.5 Conduct of Tests

X1.5.1 This test method provides two alternatives for specifying the pressure in the furnace chamber with respect to the unexposed surface. The first, which reflects typical building code provisions that reference this test method, is identified as a *standard pressure condition* and requires that the pressure in the furnace be at least 0.01 in. wg (2.5 Pa) greater than the pressure on the unexposed side of the test assembly at the location of the test specimen (firestop assembly). Other than reporting the actual pressure differentials, no further substantiation is required for tests that are conducted in accordance with the standard pressure condition. The second alternative, which is identified as a *unique pressure condition*, permits the testing of firestop assemblies with a furnace pressure that is less than the standard pressure condition. For tests conducted in accordance with this procedure, the laboratory is required to report the basis for the selected test pressure.

X1.5.2 The issue of pressure differentials that exist in real fires is complex. Normally, a fully-developed fire within an enclosed room will vent through openings, such as windows or open doorways, or both, in the compartment boundaries (walls). A positive pressure in the range of 0.03 to 0.05 in. wg (7.5 to 12.5 Pa) will exist in the upper regions of the fire compartment, due to buoyancy effects, with respect to the atmosphere to which the fire has vented. A negative pressure will exist in the lower regions of the fire compartment. This does not necessarily mean that compartment boundaries in real buildings will be exposed to these pressure differentials. For a given compartment, other pressure differentials may also exist due to the effects of wind, mechanical systems, compartment location within the building, and ambient temperature differences between the inside and outside of the building. As a consequence, during an actual fire, the pressure differential that exists across a given compartment boundary can conceivably be as great as 0.50 in. wg (125 Pa) and either positive or negative. Cooper has published one discussion of this issue (1).[3] Many other excellent references are included in the literature. As a result, the selection of any specific pressure condition for testing purposes is necessarily an arbitrary decision and users should be aware of this shortcoming.

X1.5.3 In studying this issue, the committee has considered a number of other factors. There is, for example, a general consensus that positive pressure testing represents a more severe exposure condition than negative pressure testing. Furthermore, pressure differentials tend to be more important when the test assembly includes joints or openings, or both, which is the case with this test. For some firestop systems, there is evidence that the exact magnitude of the pressure differential does not have a significant impact on performance, provided that the pressure differential is positive (2). Even though this data covers a fairly extensive range of systems and pressure conditions, it is not possible to state that this *rule-of-thumb* applies across the board. And lastly, given the design of many currently available furnaces, testing at significant levels of positive pressure can necessitate complex test equipment modifications (for example, the use of negative pressure chambers on the unexposed surface of the assembly).

X1.5.4 As a result of all of the foregoing, different regulatory authorities have specified different pressure conditions for tests of this nature (3-6). Within the United States, however, model building code provisions that reference this test method specify a minimum positive pressure differential of 0.01 in. wg (2.5 Pa) (3-5). The standard pressure condition is intended to be consistent with these requirements. Users are, however, cautioned that a greater positive pressure differential is specified in Canada in certain instances (6). Since the standard pressure condition specifies a *minimum* positive pressure differential, it is conceivable that a testing program can be carefully designed to satisfy both United States and Canadian building code requirements. As long as the specified pressure differential is positive and at least 0.01 in. wg (2.5 Pa), such tests can be conducted in complete accordance with the standard pressure condition.

X1.5.5 The unique pressure condition alternative is included in recognition of the fact that other regulatory authorities may specify different pressure conditions (including negative pressure differentials). If this alternative is used, 11.1.5 requires that the testing laboratory report the basis for the specified test pressure.

X1.5.6 Within the volume of a furnace, gas temperatures will tend to be reasonably uniform. As a result, a linear static pressure differential relationship will exist between the gases in the furnace and ambient conditions within the laboratory. Higher pressure differentials will exist in the upper portions of the furnace and lower pressure differentials in the lower portions of the furnace. The gradient of this pressure differential relationship can be calculated based upon the average furnace temperature. Even though this gradient will vary with time during the course of a test, an average gradient of approximately 0.01 in. wg/ft of height (8.2 Pa/m) will exist during the majority of a test. The vertical location of the neutral plane (that is, that elevation at which the furnace pressure is equal to the laboratory pressure) will be determined by the operating characteristics of the furnace. As a consequence, for tests involving wall assemblies, the vertical location of the test specimen (firestop assembly) with respect to the neutral plane will determine the applicable pressure differential and test specimens located at different elevations will be exposed to different pressure differentials. This test method therefore requires that the pressure differential be measured at two different elevations for vertical (wall) furnaces (6.4.1.1).

X1.5.7 For tests involving walls, two alternatives can be used to determine whether or not a test specimen (firestop assembly) has been exposed to a minimum positive pressure differential. The elevation of the neutral plane can be determined based upon the measured pressure differentials. The elevation above which the specified positive pressure differential exists can then be calculated based upon an assumed gradient of 0.01 in. wg/ ft of height (8.2 Pa/m). Test specimens located above this elevation will be exposed to the specified minimum positive pressure differential. Test specimens located below this elevation will not. Alternatively, an additional pressure probe can be located at or below the lowest elevation

[3] The boldface numbers in parentheses refer to a list of references at the end of this standard.

Copyright by the ASTM International
Wed Feb 02 02:02:57 2005

of the test specimen and this probe can be used to determine the minimum pressure differential by direct measurement.

X1.5.8 In the case of floor tests, this degree of complexity is not required since floors will typically be exposed to a uniform pressure differential. For the standard pressure condition, this test method simply requires that the min-imum positive pressure differential of 0.01 in. wg (2.5 Pa) be maintained at the elevation of the required pressure probes.

Standard Specification for Polytetrafluoroethylene (PTFE) Plastic-Lined Ferrous Metal Pipe, Fittings, and Flanges[1]

This standard is issued under the fixed designation F 423; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers factory-made polytetrafluoroethylene (PTFE) plastic-lined ferrous metal pipe, fittings, and flanges primarily intended for conveying corrosive fluids. Included are requirements for material, workmanship, dimensions, working pressure and temperature, design, fabrication, test methods, marking, as well as qualification requirements.

NOTE 1—This specification does not include products coated with PTFE.

1.2 This specification covers ANSI Class 150 and 300 PTFE-lined pipe, flanges, and fittings in nominal diameters of ½ to 24 in. Pressure limitations shall be those established by the manufacturer considering both pressure and temperature limitations of the ferrous metal housings and sealing ability of the linear at flanged joints.

1.3 The PTFE-lined flanged pipe and fitting assemblies are limited for use from −20 to 500°F (−29 to 260°C). For use below −20°F (−29°C) consult the manufacturer.

NOTE 2—The temperature limitations are based on noncorrosive test conditions. Use in specific aggressive environments may alter temperature limitations. In such instances, specific temperature limits shall be established by mutual agreement between the purchaser and manufacturer.

1.4 The values given in parentheses are provided for information purposes only.

3. Terminology

3.1 *Terminology*—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise specified. The abbreviation for polytetrafluoroethylene is PTFE.

4. Materials

4.1 *Lining:*
4.1.1 *Material*—The lining shall be made from polytetrafluoroethylene resins conforming to the requirements of Specification D 1457, except that a maximum of 1 % by weight of additives or colorants, or both, is permissible for identification or other purposes. Organic additives or colorants, or both, if used, shall be identified in the manufacturer's specification.
4.1.2 The lining shall be made from virgin resin meeting Specification D 1457 or clean unsintered reworked resin capable of meeting the performance requirements of this specification.
4.1.3 *Mechanical Properties*—When tested in accordance with Specification D 1457 the minimum longitudinal tensile strength and elongation shall be 3000 psi (21 MPa) and 250 % respectively and the transverse minimum values 2500 psi (17 MPa) and 200 %.
4.1.4 *Specific Gravity*—The linings manufactured from PTFE resins meeting Specification D 1457, Types I and IV, shall have a specific gravity from 2.14 to 2.19, and those manufactured from Type III shall have a specific gravity

[9] *Annual Book of ASTM Standards*, Vol 01.02.

from 2.13 to 2.21, when tested in accordance with Test Methods D 792 or D 1505.

4.2 *Pipe and Fittings:*

4.2.1 Mechanical properties of pipe and fitting shall conform to the requirements of the appropriate specification of Table 1 except as they are influenced by accepted methods of processing in the industry, that is, Van Stone flaring, bending, swaging, and welding. The carbon steel pipe and fittings shall be welded or seamless steel, Schedule 40 or Schedule 80, except that Schedule 30 may be used for pipe with 8 and 10-in. nominal size. Schedule 20 may be used for 12-in. nominal size and above with the agreement of the purchaser. Lighter schedules may be used by mutual agreement between the purchaser and the manufacturer.

4.2.2 *Welding*—All fusion welding shall be done by welders or welding operators using welding procedures qualified under the provisions of Section IX of the ASME Boiler and Pressure Vessel Code.

4.2.3 *Finish*—The interior surfaces of all housings shall be clean and free of mold burrs, rust, scale, or other protrusions that may adversely affect the integrity or performance of the lining.

4.3 *Back-Up Gaskets*—Back-up gaskets shall be used to cover the pipe end and gasket face of threaded or slip-on flanges unless a full radius is provided at the end of the pipe and a smooth transition is provided at the junction of the pipe and flange. Gaskets may also be required on fittings to provide accommodation or elimination, or both, of sharp corners that could damage the lining.

5. Requirements

5.1 *Dimensions:*

5.1.1 *Housings*—Housing installation dimensions are as required in the applicable material specification listed in Table 1.

5.1.2 *Wall Thickness*—Pipe and fitting linings shall have a minimum wall thickness and gasket face thickness as follows:

Minimum Linear and Gasket Face Thickness

Nominal Pipe Size, in.	Liner Wall, in. (mm)	Gasket Face Thickness, in. (mm)
1 to 4	0.050 (1.3)	0.040 (1.0)
6 to 14	0.100 (2.5)	0.080 (2.0)
16, 18	0.125 (3.2)	0.100 (2.5)
20, 24	0.150 (3.8)	0.120 (3.0)

5.1.3 *Lining Flare Diameter*—The outside diameter of the PTFE flare covering the gasket face portion of the flange or the full face of the lap-joint stub end shall not be less than the diameter specified in Table 2. The flared portion of the lining shall be concentric with the flared portion of the pipe within 1/16 in. (1.6 mm).

5.1.4 *Tolerances*—Tolerances for pipe, flanges, and fittings shall be as specified in Table 3. Bolt holes in both flanges on a fixed flange spool shall straddle the same center line to facilitate alignment. Finished lined (plastic flare to plastic flare) fabricated fittings shall conform to the nominal face-to-face dimensions as specified in ANSI B16.42 or B16.5 with the applicable tolerances.

TABLE 2 PTFE Flare Diameter

Nominal Pipe Size, in.	Minimum PTFE Flare Diameter, in. (mm)
1/2	1 1/4 (31.8)
3/4	1 9/16 (39.7)
1	1 7/8 (47.6)
1 1/2	2 11/16 (68.3)
2	3 7/16 (87.3)
3	4 5/8 (117.5)
4	5 15/16 (150.8)
6	8 (203.2)
8	10 1/16 (255.6)
10	12 1/4 (311.2)
12	14 3/8 (365.1)
14	15 1/2 (393.7)
16	17 3/4 (450.9)
18	20 1/4 (514.4)
20	22 1/4 (565.2)
24	26 1/4 (666.8)

Copyright by the ASTM International
Wed Feb 02 02:03:29 2005

TABLE 3 Tolerances for Pipe, Flanges, and Fittings, in. (mm)

Pipe:	
Length	±⅛ (±3.2)
Fixed flange bolt hole alignment	±1/16 (±1.6)
Flange perpendicularity (with pipe centerline)	3/32 in./ft (7.8 mm/m) of diameter
Flanges:	
All dimensions	See ANSI B16.42 or ANSI B16.5
Fittings:	
All dimensions	See ANSI B16.42 or ANSI B16.5

5.2 *Flange Construction:*

5.2.1 Screw-type flanges shall be secured in position to prevent inadvertent turning of the flange.

5.2.2 Socket-type flanges shall be fully backwelded to the pipe housing and the inside surfaces of the socket flanges shall be ground smooth.

5.2.3 Slip-on flanges shall be fully backwelded.

NOTE 3—No welding *shall be done* on lined components in the field unless absolutely necessary and then only under the supervision of experienced and qualified personnel, since excessive heat can cause linear decomposition and failure. It is recommended that lined components be hydrostatically tested as specified in 6.2.1.1 after any welding in the field.

5.2.3.1 Modified slip-on flanges used as lap-joint flanges may be used with flared laps formed by flaring the pipe. The radius of the fillet of the flared lap shall not exceed ⅛ in. (3.8 mm) and the backing flange for the flared metallic lap shall have a ⅛-in. bevel or ⅛-in. corner radius at the bore to provide clearance for the fillet of the flared lap. The outside diameter of the flared lap shall be in accordance with the dimensions of an ANSI B16.9 lap-joint stub.

5.2.4 Lap-joint (or Van Stone) flanged ends may be manufactured by standard forming techniques or by using fully welded Type A MSS SP-43 or ANSI B16.9 lap-joint stub ends. Van Stone flares shall have a fillet radius compatible with the corner radius of the mating flange and shall not contain any cracks or buckles. Van Stone flares and stub ends shall have a radius to provide a smooth transition for the PTFE flare. Only lap joint flanges in accordance with ANSI B16.42 and B16.5 shall be used.

5.3 *Venting*—Each pipe and fitting shall be provided with a venting system that will release any pressure between the liner and the housing.

NOTE 4—A series of 1/16 to 5/32-in. (1.6 to 4.0-mm) diameter holes in the housings, or a helical groove system inside the housing, that connects flange vents, has provided adequate venting.

5.4 *Workmanship:*

5.4.1 Pipe and fitting linings shall show no evidence of pinholes, porosity, or cracks when inspected in accordance with 5.5.2. The linings shall fit snugly inside the pipe and fitting housings. Any bulges or other obvious indication of poor contact with the housing shall be cause for rejection.

5.4.2 The gasket seating surface of the linings shall be free of surface defects that could impair sealing effectiveness. Scratches, dents, nicks, or tool marks on the seating surface shall not be deeper than 10 % of the wall thickness.

5.5 *Performance:*

5.5.1 *Qualification*—Lined pipe and fittings must be capable of meeting the qualification requirements specified in 6.1.

5.5.2 *Inspection*—Each spool and fitting, prior to shipment, shall be hydrostatically or spark tested in accordance with 6.2.1.1 or 6.2.1.2 and shall subsequently be visually inspected to verify conformance to the requirements of 5.4.

6. Test Methods

6.1 *Qualification Tests:*

6.1.1 *Temperature Test*—Cycle representative production samples of lined pipe and fittings in an oven from room temperature to 500°F (260°C) to determine the ability of the lined components to withstand heat aging and temperature cycling. Test a minimum of two pipe spools, tees, and 90° elbows in each size.

6.1.1.1 *Test Method*—Install blind flanges with a center vent hole at the manufacturer's recommended torque value, and affix a thermocouple to the ferrous housing to measure the temperature. Pipe spools shall be at least 3 ft (1 m) long up to the 4-in. size and 10 pipe diameters in sizes 6 in. and larger to a 10-ft (3-m) maximum length. After 1 h in an oven at 500°F (260°C) as indicated by the thermocouple, air cool the lined component to 122°F (50°C) maximum. Repeat this test for a total of three cycles.

6.1.1.2 *Inspection*—Inspect lined pipe and fittings after each cycle for distortion or cracks in the lining. At the completion of the third cycle, subject tested specimens to the hydrostatic or electrostatic test described in 6.2.1.1 or 6.2.1.2.

6.1.2 *Steam-Cold Water Cycling Test*—Subject representative production samples of lined pipe and fittings to steam-cold water cycling to determine the ability of the lined components to withstand rapid temperature changes. Test a minimum of two pipe spools, tees, and 90° elbows in each size.

6.1.2.1 *Test Method*—Assemble lined pipe and fitting with suitable blind flanges having provision for the introduction of steam, air, cold water, and for drainage. Install the flanges using the manufacturer's recommended torque value. Pipe spool length shall be 10 ft (3 m). Mount the sample in such a manner as to permit complete drainage and venting. Then subject it to 100 consecutive steam-cold water cycles, each consisting of the following in the sequence given:

(*1*) Circulate 125 ± 5 psi (862 ± 35 kPa) gage saturated steam through the sample until the ferrous housing skin temperature adjacent to the flange at the outlet end of the sample has been maintained at the maximum stabilized temperature for 10 min.

(*2*) Close off steam.

(*3*) Circulate water at a maximum temperature of 77°F (25°C). Circulate the cooling water until the ferrous housing skin temperature adjacent to the flange at the outlet end of the sample measures 122°F (50°C).

(*4*) Vent and introduce air to purge the sample for a minimum of 1 min, making certain that it is completely drained of water.

6.1.2.2 *Inspection*—There shall be no evidence of leakage from the venting system during the 100 cycles. At the completion of the test, the liner shall evidence no buckling, cracking, or crazing. Formation of water blisters shall not be cause for rejection.

NOTE 5—These surface blisters are formed due to absorption of the steam vapors by the liner and subsequent condensation in the liner. The blisters do not adversely affect liner performance.

Copyright by the ASTM International
Wed Feb 02 02:03:29 2005

6.1.2.3 Subject the lined pipes or fittings to either the hydrostatic test described in 6.2.1.1 or, after drying, to the electrostatic test described in 6.2.1.2.

6.1.3 *Vacuum Testing*—Test representative production samples of lined pipe and fittings to determine the vacuum ratings of the lined components. Test a minimum of two pipe spools, tees, and 90° elbows in each size. Conduct tests at room temperature, at the manufacturer's maximum recommended service temperature, and at two intermediate temperature levels.

NOTE 6—Vacuum-temperature ratings for pipe and fittings are published in the manufacturers' literature.

NOTE 7—The above vacuum test is performed on pipe and fittings that have not been exposed to prior service. Use in specific environments may alter the vacuum-temperature ratings and these shall be established by mutual agreement between purchaser and manufacturer.

6.1.3.1 *Test Method*—For pipe spools, specimen length shall be at least ten pipe diameters. Install a flange incorporating a sight glass at one end and a blind flange suitable for drawing a vacuum at the other end. Make provision for measuring the ferrous housing temperature. Uniformly heat the specimen externally with the sight glass end visible, and after reaching the desired ferrous housing temperature, begin the test. Hold a selected initial vacuum level for a minimum of 8 h and if no failure occurs, increase the vacuum by 5 in. Hg (17 kPa) up to the 4-in. size and by 2 in. Hg (6.8-kPa) increments for sizes 6 in. and larger. Repeat for 8-h minimum periods until failure or full vacuum is reached. Failure is defined as any buckling or collapse of the liner. If failure occurs at the initial vacuum level selected, test a new specimen at a lower vacuum level to determine the failure threshold. The failure threshold vacuum is defined as 1 in. Hg (3.4 kPa) below that at which failure occurs.

NOTE 8—The external pressure method can be used to simulate higher than full vacuum to establish the failure threshold when full vacuum does not produce failure. With the use of pressure taps, an external pressure is applied between the liner outside diameter and the pipe inside diameter.

6.1.3.2 Set the vacuum ratings 20 % below the failure threshold.

6.1.3.3 At the test completion and after establishing the vacuum rating, place a duplicate specimen in an oven at the test temperature. Apply the rated vacuum to the specimen after the desired skin temperature has been reached. Achieve the rated vacuum within 2 min and apply continuously for 48 h. If no liner buckling or collapse occurs, the rated vacuum shall be considered acceptable.

6.1.4 *Retest*—When a test specimen fails to meet the requirements of either 6.1.1.2, 6.1.2.2, or 6.1.3.3, seek and correct the cause of failure and repeat the specified test, doubling the number of test specimens.

6.2 *Inspection Requirements:*

6.2.1 *Hydrostatic or Electrostatic Testing*—Subject each lined pipe and fitting, prior to shipment, to a hydrostatic test or electrostatic test as specified in 6.2.1.1 or 6.2.1.2. The test to be used shall be at the option of the manufacturer, unless otherwise specified by the purchaser.

6.2.1.1 *Hydrostatic Pressure Test*—The internal test pressure shall be 400 psi (2758 kPa) minimum, and the test shall be conducted at ambient temperature. Fill the pipe or fitting completely with clean water and bleed the system free of all air prior to the application of pressure. Reach full test pressure within 1 min and maintain for 3 min. Observe the pressure gage and the venting system in the test specimen throughout the pressure test for any evidence of leakage, which shall be cause for rejection.

6.2.1.2 *Electrostatic Test*—Conduct the test with a nondestructive high-voltage tester at an output voltage of 10 000 V. A visible or audible spark, or both, that occurs at the probe when electrical contact is made because of a defect in the liner, shall be cause for rejection.

6.2.2 *Final Inspection*—After the requirements of 6.2.1 have been met, visually inspect each lined pipe and fitting prior to shipment to verify conformance to the design and dimensional requirements of this specification and 5.4.

6.2.3 Each spool or fitting shall bear an inspection verification mark on the housing to indicate compliance with the requirements of this specification.

7. Finish

7.1 The outside surface of all lined pipe and fittings shall be coated with a corrosion-resistant primer over a properly prepared surface.

8. Marking

8.1 *Quality of Marking*—The markings shall be applied to the pipe in such a manner that it remains legible (easily read) after installation and inspection have been completed.

8.2 The pipe and fittings shall be marked with the following information:

8.2.1 Nominal pipe size,

8.2.2 Liner material identification (PTFE),

8.2.3 Manufacturer's name (or trademark),

8.2.4 This designation "ASTM F 423," and

8.2.5 Length (on pipe only).

8.3 Other information such as, order numbers, part numbers, item numbers, etc., shall be provided at the request of the purchaser.

8.4 Pipe liner identification shall be provided on a band containing the raised letters "PTFE." The band shall typically be located near the flange.

9. Packaging

9.1 The gasket face of each spool shall be protected by end plates or other suitable protective means.

9.2 Fittings shall have the same protective covers on the gasket faces unless protected by other means, such as individual boxing.

10. Federal Procurement

10.1 *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

Copyright by the ASTM International
Wed Feb 02 02:03:30 2005

NOTE 9—In federal contracts, the contractor is responsible for inspection.

10.2 *Packaging and Marking for U.S. Government Procurement:*

10.2.1 *Packaging*—Unless otherwise specified in the contract, the material shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition, and that will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules.

10.2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE 10—The inclusion of U.S. Government procurement requirements shall not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

11. Quality Assurance

11.1 When the product is marked with this designation, F 423, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Standard Specification for Threaded Chlorinated Poly(Vinyl Chloride) (CPVC) Plastic Pipe Fittings, Schedule 80[1]

This standard is issued under the fixed designation F 437; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers chlorinated poly(vinyl chloride) (CPVC) threaded Schedule 80 pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—The CPVC fittings covered by this specification were covered previously in Specification D 2464.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 2—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious safety hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are given for information only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions are in accordance with Terminology F 412 and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for chlorinated poly(vinyl chloride) is CPVC.

4. Classification

4.1 *General*—This specification covers threaded Schedule 80 CPVC pipe fittings, intended for use with threaded Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings, caps, nipples, etc., shall be molded or machined from extruded stock.

4.1.2 Fittings fabricated by backwelding are not included in this specification.

5. Materials and Manufacture

5.1 This specification covers CPVC pipe fittings made from compounds meeting the requirements of Class 23447 as defined in Specification D 1784.

NOTE 3—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.2 *Rework Material*—The manufacturers shall use only their own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *Dimensions and Tolerances*:

6.1.1 The dimensions and tolerances of the fittings shall be as shown in Table 1 and Table 2 when measured in accordance with Test Method D 2122. Minimum dimensions have zero negative tolerances. Bushings shall have thread lengths applicable to the corresponding sizes. Counterbore, which is optional, is not shown in Table 1, and is not included in the center-to-end or end-to-end dimensions.

6.1.2 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

6.1.3 *Fittings Not Illustrated*—All fittings, whether illustrated in Table 1 and Table 2 or not, shall have wall thicknesses and thread dimensions conforming to 6.1 and 6.2.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.3.1 The minimum burst strength of the fittings shall be not less than that calculated for the size and wall thickness of the pipe with which it is to be used, when calculated from the following equation:

$$S = P(D_o - t)/2t \quad (1)$$

where:

S = hoop stress, psi (or MPa),
P = internal pressure, psi (or MPa),
D_o = average outside diameter, in. (or mm), and
t = minimum wall thickness, in. (or mm).

Fittings tested in accordance with 8.5 shall withstand the minimum burst pressure shown in Table 3.

6.3.2 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish, and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the Standard Laboratory Atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 4—For individual orders or specifications where supplemental

TABLE 3 Burst Pressure Requirements for Water at 73°F (23°C) for CPVC Threaded Pipe Fittings, Schedule 80

Nominal Size, in.	Min Burst Strength[A] Class 23447	
	psi	(MPa)
1/4	3620	(24.96)
3/8	2940	(20.27)
1/2	2720	(18.75)
3/4	2200	(15.17)
1	2020	(13.93)
1 1/4	1600	(11.44)
1 1/2	1510	(10.41)
2	1290	(8.89)
2 1/2	1360	(9.38)
3	1200	(8.27)
4	1040	(7.17)
6	890	(6.14)

[A]This table was calculated for Schedule 80 pipe using the ISO formula and a stress level as follows:

	psi	MPa
Class 23447 (Type IV Grade 1 (CPVC))	6400	44.1

tests are required, only those tests and numbers of tests specifically agreed upon between the purchaser and seller need be conducted.

8.4 *Threads*—All taper pipe threads shall be gaged in accordance with Specification F 1498.

8.5 *Burst Pressure*—Determine the minimum burst pressure with at least five specimens in accordance with Test Method D 1599. Join the fittings to the pipe sufficiently strong and in such a manner that no failures shall occur in the assembly at a pressure less than the pressure requirement given in Table 3. The time of testing each assembly shall be between 60 and 70 s.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the tests(s) shall be conducted again only by agreement between the purchaser and seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Product Marking

10.1 *Quality of Marking*—The markings shall be applied to the fittings in such a manner that they remain legible under normal handling and installation practices.

10.2 *Content of Marking*:

10.2.1 Fittings shall be marked with the following:

10.2.1.1 Manufacturer's name or trademark,

10.2.1.2 Material designation CPVC for CPVC 23447,

10.2.1.3 The seal or mark of the laboratory making the evaluation for potable water contact,

10.2.1.4 Size, and

10.2.1.5 This designation "F 437," with which the fitting complies.

10.3 Where the size of the fitting does not allow complete marking, omit identification marking in the following sequence: size, material designation, F 437, manufacturer's name or trademark.

10.4 Markings or symbols shall be molded, hot-stamped, or applied to fittings by any other suitable method, such as printing.

10.5 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

11. Quality Assurance

11.1 When the product is marked with this designation, F 437, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this

Copyright by the ASTM International
Wed Feb 02 02:04:00 2005

specification and has been found to meet the requirements of this specification.

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to Federal/Military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S3. Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: F 438 – 01

An American National Standard

Standard Specification for Socket-Type Chlorinated Poly(Vinyl Chloride) (CPVC) Plastic Pipe Fittings, Schedule 40[1]

This standard is issued under the fixed designation F 438; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers chlorinated poly(vinyl chloride) (CPVC) Schedule 40 socket-type pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—The CPVC fittings covered by this standard were covered previously in Specification D 2466.

1.2 The products covered by this specification are intended for use with the distribution of pressurized liquids only, which are chemically compatible with the piping materials. Due to inherent hazards associated with testing components and systems with compressed air or other compressed gases some manufacturers do not allow pneumatic testing of their products. Consult with specific product/component manufacturers for their specific testing procedures prior to pneumatic testing.

NOTE 2—Pressurized (compressed) air or other compressed gases contain large amounts of stored energy which present serious saftey hazards should a system fail for any reason.

1.3 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.4 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are given for information only.

1.5 The following safety hazards caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

D 1784 Specification for Rigid Poly(Vinyl Chloride) (PVC) Compounds and Chlorinated Poly(Vinyl Chloride) (CPVC) Compounds[2]

D 2122 Test Method for Determining Dimensions of Thermoplastic Pipe and Fittings[3]

D 2749 Symbols for Dimensions of Plastic Pipe Fittings[3]

F 412 Terminology Relating to Plastic Piping Systems[3]

F 1498 Specification for Taper Pipe Threads 60° for Thermoplastic Pipe and Fittings[3]

2.2 *Federal Standard:*

Fed. Std. No. 123 Marking for Shipment (Civil Agencies)[4]

2.3 *Military Standard:*

MIL-STD-129 Marking for Shipment and Storage[5]

2.4 *NSF Standard:*

Standard No. 14 for Plastic Piping Components and Related Materials[5]

3. Terminology

3.1 *Definitions:*

3.1.1 Definitions are in accordance with Terminology F 412 and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for chlorinated poly(vinyl chloride) is CPVC.

4. Classification

4.1 *General*—This specification covers Schedule 40 CPVC pipe fittings, socket-type, intended for use with Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings, caps, nipples, etc., shall be molded or machined from extruded stock.

4.1.2 Fittings fabricated by backwelding are not included in this specification.

---

5. Materials and Manufacture

5.1 This specification covers CPVC pipe fittings made from compounds meeting the requirements of Class 23447 as defined in Specification D 1784.

NOTE 3—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.2 *Rework Material*—The manufacturers shall use only their own clean rework fitting material and the fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *Dimensions and Tolerances*:

6.1.1 Fitting sockets, inside diameters (waterways), minimum wall thicknesses, and dimensions shall be as shown in Table 1, Table 2, and Table 3 when measured in accordance with Test Method D 2122.

6.1.2 When multistep reducer bushings are cored out, the inner socket shall be reinforced from the outer wall by a minimum of three ribs extending from the top of the inner socket in the deepest extremity of the coring. The transition from D to DJ (Table 3) shall be straight, tapered as shown, or radiused. A positive taper in the same direction of the taper in the socket on the outside diameter of the bushing is optional.

6.1.3 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

6.1.4 The minimum wall thickness of fittings shall be 125 % of the minimum wall thickness of the corresponding size of Schedule 40 pipe for which they are designed to be used, except that for the socket, the wall thickness shall be at least equal to the minimum wall thickness of the corresponding size of Schedule 40 pipe. For any threaded transition fitting the minimum wall thickness of the threaded portion shall be at least equal to the thickness of material under the thread root of threaded Schedule 80 pipe of the same size.

6.1.5 The minimum inside diameter of the fittings shall be not less than the minimum specified inside diameter of the corresponding size of Schedule 40 pipe. Any fitting having a male thread shall have an internal diameter not larger than Schedule 80 pipe of the same size.

6.1.6 Minimum dimensions have zero negative tolerance. Tolerances on other dimensions are shown in Table 1 and Table 3.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.3.1 The minimum burst strength of the fittings shall be not less than that calculated for the size and wall thickness of the pipe with which it is to be used, when calculated from the following equation:

$$S = P (D_O - t)/2t \quad (1)$$

where:

S = hoop stress, psi (or MPa),
P = internal pressure, psi (or MPa),
D_O = average outside diameter, in. (or mm), and
t = minimum wall thickness, in. (or mm).

Fittings tested in accordance with 8.5 shall withstand the minimum burst pressure shown in Table 4.

6.3.2 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish, and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition the test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the Standard Laboratory Atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 4—For individual orders or specifications where supplemental tests are required, only those tests and numbers of tests specifically agreed upon between the purchaser and the seller need be conducted.

8.4 *Threads*—All taper pipe threads shall be gaged in accordance with Specification F 1498.

8.5 *Burst Pressure*—Determine the minimum burst pressure in accordance with Test Method D 1599. The time of testing each specimen shall be between 60 and 70 s.

8.5.1 *Apparatus*—Fittings shall be tested while held in a test jig constructed in such a manner as to seal the socket by means of O-rings, or gaskets but not to reinforce or support the fittings, except where contact is necessary because of the shape of the fitting to keep the fitting in the test jig. Such contact shall be held to the minimum. The socket plug portion of the test fixture must extend one third to two thirds of the socket depth. Failure of any part of the test apparatus does not constitute failure of the fittings.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the tests(s) shall be conducted again only by agreement between the purchaser and seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Product Marking

10.1 *Quality of Marking*—The markings shall be applied to the fittings in such a manner that they remain legible under normal handling and installation practices.

10.2 *Content of Marking*:

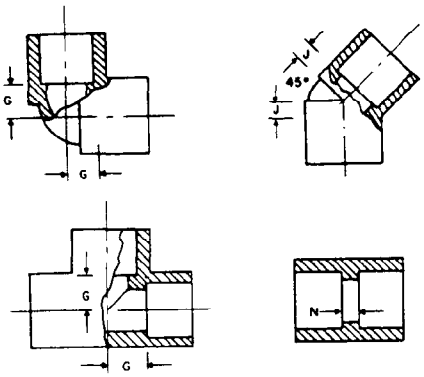
TABLE 2 Minimum Dimension from Center to End of Sockets (Laying Length) for Couplings, Tees, 90° and 45° Elbows, CPVC Socket-Type Pipe Fittings, Schedule 40, in. (mm)[A]



Nominal Pipe Size	*G*, min in. (mm)	*J*, min in. (mm)	*N*, min in. (mm)
¼	5/16 (7.94)	5/32 (3.97)	1/16 (1.59)
⅜	⅜ (9.53)	3/16 (4.76)	3/32 (2.38)
½	½ (12.70)	¼ (6.35)	3/32 (2.38)
¾	9/16 (14.29)	5/16 (7.94)	3/32 (2.38)
1	11/16 (17.46)	5/16 (7.94)	3/32 (2.38)
1¼	⅞ (22.22)	⅜ (9.53)	3/32 (2.38)
1½	1 (25.40)	7/16 (11.11)	3/32 (2.38)
2	1¼ (31.75)	⅝ (15.88)	3/32 (2.38)
2½	1½ (38.10)	11/16 (17.46)	3/16 (4.76)
3	1 13/16 (46.04)	¾ (19.05)	3/16 (4.76)
3½	2⅛ (53.98)	1 (25.40)	3/16 (4.76)
4	2 5/16 (58.74)	1 (25.40)	3/16 (4.76)
5	3 (76.20)	1⅜ (34.92)	3/16 (4.76)
6	3½ (88.90)	1¾ (44.45)	¼ (6.35)

[A] The sketches and designs of fittings are illustrative only.

10.2.1 Fittings shall be marked with the following:

10.2.1.1 Manufacturer's name or trademark,

10.2.1.2 Material designation CPVC for CPVC 23447,

10.2.1.3 The seal or mark of the laboratory making the evaluation for potable water contact,

10.2.1.4 Size, and

10.2.1.5 This designation F 438, with which the fitting complies.

10.3 Where the size of the fitting does not allow complete marking, omit identification marking in the following sequence: size, material designation, F 438, manufacturer's name or trademark.

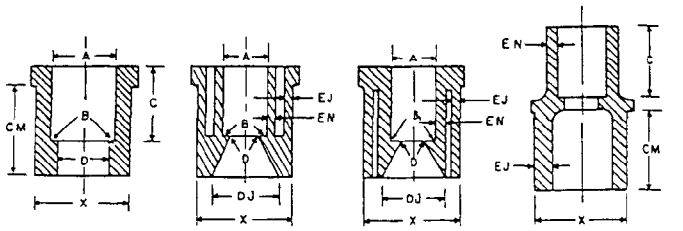
10.4 Markings or symbols shall be molded, hot-stamped, or applied to fittings by any other suitable method, such as printing.

10.5 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

11. Quality Assurance

11.1 When the product is marked with this designation, F 438, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

TABLE 3 Dimensions of Reducer Bushings, CPVC Socket-Type Pipe Fittings, Schedule 40,[A] in.



Nominal Size	*X*, Outside Diameter	Tolerance on Outside Diameter (includes out-of-round)
⅜ by ¼	0.675	0.016 (0.41)
½ by ⅜, ¼	0.840	0.016 (0.41)
¾ by ½, ⅜, ¼	1.050	0.020 (0.51)
1 by ½, ¾	1.315	0.020 (0.51)
1¼ by ½, ¾, 1	1.660	0.024 (0.61)
1½ by ½, ¾, 1, 1¼	1.900	0.024 (0.61)
2 by ½, ¾, 1, 1¼, 1½	2.375	0.024 (0.61)
2½ by 2	2.875	0.030 (0.76)
3 by 2½, 2	3.500	0.030 (0.76)
3½ by 2½, 2	4.000	0.030 (0.76)
4 by 3½, 3, 2½, 2	4.500	0.030 (0.76)
5 by 4	5.563	0.060 (1.52)
6 by 5	6.625	0.070 (1.78)

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to Federal/Military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2.1—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

POTABLE WATER REQUIREMENT

This requirement applies whenever a Regulatory Authority or user calls for product to be used to convey or to be in contact with potable water.

S3. Products intended for contact with potable water shall be evaluated, tested and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Designation: F 439 – 01

Standard Specification for Chlorinated Poly (Vinyl Chloride) (CPVC) Plastic Pipe Fittings, Schedule 80[1]

This standard is issued under the fixed designation F 439; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

1. Scope

1.1 This specification covers chlorinated poly(vinyl chloride) (CPVC) Schedule 80 pipe fittings. Included are requirements for materials, workmanship, dimensions, and burst pressure.

NOTE 1—The threaded CPVC fittings covered by this specification were covered previously in Specification F 437.

1.2 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this specification.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values in parentheses are given for information only.

1.4 The following safety hazards caveat pertains only to the test method portion, Section 8, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.3 *Military Standard:*

MIL-STD-129 Marking for Shipment and Storage[4]

2.4 *NSF Standard:*

Standard No. 14 for Plastic Piping Components and Related Materials[5]

Standard No. 61 for Drinking Water System Components—Health Effects[5]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology F 412 and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated. The abbreviation for chlorinated poly(vinyl chloride) is CPVC.

4. Classification

4.1 *General*—This specification covers Schedule 80 CPVC pipe fittings, intended for use with Iron Pipe Size (IPS) outside-diameter plastic pipe.

4.1.1 Fittings covered by this specification are normally molded. In-line fittings, such as couplings, unions, bushings, caps, nipples, and so forth, shall be molded or machined from extruded stock.

4.1.2 Fittings fabricated by back welding or butt fusion are not included in this specification.

5. Materials and Manufacture

5.1 This specification covers CPVC pipe fittings made from compounds meeting the requirements of Class 23447 and Class 23448 as defined in Specification D 1784.

NOTE 2—Mechanical strength, heat resistance, flammability, and chemical resistance requirements are covered in Specification D 1784.

5.2 *Rework Material*—The manufacturers shall use only their own clean rework fitting material, and the fittings produced shall meet all the requirements of this specification.

6. Requirements

6.1 *Dimensions and Tolerances*:

6.1.1 Fitting sockets, inside diameters (waterways), minimum wall thicknesses, and dimensions shall be as shown in Tables 1-5 when measured in accordance with Test Method D 2122.

6.1.2 When multistep reducer bushings are cored out, the inner socket shall be reinforced from the outer wall by a minimum of three ribs extending from the top of the inner socket to the deepest extremity of the coring. The transition from D to DJ (Table 3) shall be straight, tapered as shown, or radiused. A positive taper in the same direction of the taper in the socket on the outside diameter of the bushing is optional.

6.1.3 The maximum angular variation of any opening shall be not more than ½° off the true centerline axis.

6.1.4 The minimum wall thickness of fittings shall be 125 % of the minimum wall thickness of the corresponding size of Schedule 80 pipe for which they are designed to be used, except that for the socket, the wall thickness shall be at least equal to the minimum wall thickness of the corresponding size of Schedule 80 pipe.

6.1.5 The minimum inside diameter of the fittings shall be not less than the minimum specified inside diameter of the corresponding size of Schedule 80 pipe. This is calculated as follows:

$$(\text{minimum OD}) - 2 \times (\text{maximum wall}) = \text{minimum ID} \quad (1)$$

6.1.6 Minimum dimensions have zero negative tolerance. Tolerances on other dimensions are shown in Tables 1 and 3.

6.1.7 *Fitting Not Illustrated*—All fittings, whether illustrated in Tables 1-5 or not, shall maintain the dimensions conforming to 6.1 and 6.2.

6.2 *Threads*—For all fittings having taper pipe threads, threads shall conform to Specification F 1498 and be gaged in accordance with 8.4.

6.3 *Burst Pressure*:

6.3.1 The minimum burst strength of the fittings shall be not less than that calculated for the size and wall thickness of the pipe with which it is to be used, when calculated from the following equation:

$$S = P(D_O - t)/2t \quad (2)$$

where:

S = hoop stress, psi (MPa),
P = internal pressure, psi (MPa),
D_O = average outside diameter, in. (mm), and
t = minimum wall thickness, in. (mm).

Fittings tested in accordance with 8.5 shall withstand the minimum burst pressure shown in Table 6.

6.3.2 Pressures shown are minimum burst pressures and do not imply rated working pressures. The burst pressure shall be used only as an indication of quality.

7. Workmanship, Finish and Appearance

7.1 The fittings shall be homogeneous throughout and free of cracks, holes, foreign inclusions, or other defects. The fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

8. Test Methods

8.1 *Conditioning*—Condition of test specimens at 73.4 ± 3.6°F (23 ± 2°C) and 50± 5 % relative humidity for not less than 40 h prior to test in accordance with Procedure A of Practice D 618, for those tests where conditioning is required.

8.2 *Test Conditions*—Conduct tests in the standard laboratory atmosphere of 73.4 ± 3.6°F (23 ± 2°C) and 50 ± 5 % relative humidity, unless otherwise specified in the test methods or in this specification.

8.3 *Sampling*—A sufficient quantity of fittings as agreed upon between the seller and the purchaser shall be selected at random from each lot or shipment and tested to determine that the basic design is in conformance with this specification.

NOTE 3—For individual orders or specifications where supplemental tests are required, only those tests and numbers of tests specifically agreed upon between the purchaser and the seller need be conducted.

8.4 *Threads*—All taper pipe threads shall be gaged in accordance with Specification F 1498.

8.5 *Burst Pressure*—Determine the minimum burst pressure in accordance with Test Method D 1599. The time of testing each specimen shall be between 60 and 70 s.

9. Retest and Rejection

9.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and the seller. Under such agreement, minimum requirements shall not be lowered, changed, or modified, nor shall specification limits be changed. If upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

10. Marking

10.1 *Quality of Marking*—The markings shall be applied to the fitting in such a manner that they remain legible under normal handling and installation practices.

10.2 *Content of Marking*:

10.2.1 Fittings shall be marked with the following:

10.2.1.1 Manufacturer's name or trademark,

10.2.1.2 Material designation CPVC for CPVC 23447 and designation CPVC 42 for CPVC 23448,

10.2.1.3 The seal or mark of the laboratory making the evaluation for potable water contact,

10.2.1.4 Size, and

10.2.1.5 This designation "F 439," with which the fitting complies.

10.3 Where the size of the fitting does not allow complete marking, omit identification marking in the following sequence: size, material designation, F 439, and the manufacturer's name or trademark.

10.4 Markings or symbols shall be molded, hot-stamped, or applied to fittings by any other suitable method, such as printing.

10.5 Where recessed marking is used, care shall be taken to see that in no case marking causes cracks or reduces the wall thickness below the minimum specified.

6	1.44 (36.58)	1.50 (35.10)	2.000 (50.80)	0.504 (12.80)	0.500 (12.10)	2.125 (53.98)	7.625 (193.68)

[A] The sketches and designs of fittings shown are illustrative only.
[B] Symbols for dimensions are in accordance with Symbols D 2749.
[C] At the manufacturer's option, the head of the plug shall be hexagonal, octagonal, square, or round.

TABLE 6 Burst Pressure Requirements for Water at 73°F (23°C) for CPVC Pipe Fittings, Schedule 80

Nominal Size, in.	Minimum Burst Strength[A]	
	Class 23447	
	psi	MPa
¼	3620	24.96
⅜	2940	20.27
½	2720	18.75
¾	2200	15.17
1	2020	13.93
1¼	1660	11.44
1½	1510	10.41
2	1290	8.89
2½	1360	9.38
3	1200	8.27
3½	1110	7.65
4	1040	7.17
5	930	6.41
6	890	6.14
8	790	5.45

[A] This table was calculated for Schedule 80 pipe using the ISO formula and a stress level as follows:

	psi	MPa
Class 23447 (CPVC)	6400	44.1
Class 23448 (CPVC 42)	6400	44.1

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply only to Federal/Military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

Copyright by the ASTM International
Wed Feb 02 02:05:12 2005

NOTE S1.1—In U.S. Federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2.1—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

POTABLE WATER REQUIREMENT

This requirement applies whenever a regulatory authority or user calls for the product to be used to convey or to be in contact with potable water.

S3. Products intended for contact with potable water shall be evaluated, tested, and certified for conformance with ANSI/NSF Standard No. 61 or the health effects portion of NSF Standard No. 14 by an acceptable certifying organization when required by the regulatory authority having jurisdiction.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

This standard is copyrighted by ASTM, 100 Barr Harbor Drive, PO Box C700, West Conshohocken, PA 19428-2959, United States. Individual reprints (single or multiple copies) of this standard may be obtained by contacting ASTM at the above address or at 610-832-9585 (phone), 610-832-9555 (fax), or service@astm.org (e-mail); or through the ASTM website (www.astm.org).

Standard Specification for Poly(Vinylidene Fluoride) (PVDF) Plastic-Lined Ferrous Metal Pipe and Fittings[1]

This standard is issued under the fixed designation F 491; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers factory-made poly(vinylidene fluoride) (PVDF) plastic-lined ferrous metal pipe and fittings, primarily intended for conveying corrosive liquids and gases. Requirements for materials, workmanship, dimensions, design, construction, working pressures and temperatures, test methods, and markings are included.

NOTE 1—This specification does not include products *coated* with PVDF nor does it define the suitability of PVDF-lined components in chemical environments.

1.2 The ferrous piping products shall meet the requirements of the relevant specification listed in 1.2.1. Nominal sizes from 1 through 10 in. in 150 and 300-psi ratings are covered.

1.2.1 *For Ferrous Pipe:*

Title of Specification	ASTM Designation
Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless (Types E and S)	A 53
Seamless Carbon Steel Pipe for High-Temperature Service	A 106
Electric-Resistance Welded Steel Pipe	A 135
Electric-Welded Low-Carbon Steel Pipe for the Chemical Industry	A 587
Seamless and Welded Austenitic Stainless Steel Pipe	A 312
Electric-Resistance Welded Carbon and Alloy Steel Mechanical Tubing	A 513

1.2.2 *For Ferrous Flanges:*

Title of Specification	ASTM Designation
Forgings, Carbon Steel, for Piping Components	A 105
Forged or Rolled Steel Pipe Flanges, Forged Fittings and Valves and Parts for General Service	A 181
Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service	A 182
Carbon-Steel Castings Suitable for Fusion Welding for High-Temperature Service (Grade WCB)	A 216
Ferritic Ductile Iron Pressure Retaining Castings for Use at Elevated Temperatures (60-40-18)	A 395
Ductile Iron Castings (60-40-18, 64-45-12, 80-55-06)	A 536

1.2.3 *For Ferrous Fittings:*

Title of Specification	ASTM Designation
Forgings, Carbon Steel, for Piping Components	A 105
Forged or Rolled Steel Pipe Flanges, Forged Fittings, and Valves and Parts for General Service	A 181
Carbon Steel Castings Suitable for Fusion Welding for High-Temperature Service (Grade WCB)	A 216
Piping Fittings of Wrought Carbon Steel and Alloy Steel for Moderate and Elevated Temperatures	A 234
Austenitic Steel Castings for High-Temperature Service	A 351
Alloy Steel Castings Specially Heat-Treated for Pressure-Containing Parts Suitable for High-Temperature Service	A 389
Ductile Iron Castings (60-40-18, 64-45-12, 80-55-06)	A 536
Ferritic Ductile Iron Pressure Retaining Castings for Use at Elevated Temperatures (60-40-18)	A 395
Wrought Austenitic Stainless Steel Piping Fittings	A 403

NOTE 2—The PVDF sealing faces may prevent achievement of the full pressure rating of the ferrous housings. For pressure limitations, the manufacturer should be consulted.

1.3 The PVDF-lined flanged pipe and fitting assemblies are limited to use from −18 to 135°C (0 to 275°F). For use below −18°C (0°F) consult the manufacturer. Use in specific aggressive environments may alter the above temperature range. The operating temperature limits shall be established by mutual agreement between the purchaser and the seller.

D 3222 Specification for Unmodified Poly(Vinylidene Fluoride) (PVDF) Molding, Extrusion and Coating Materials[3]

F 412 Terminology Relating to Plastic Piping Systems[4]

2.2 *ANSI Standard:*

B16.5 Steel Pipe Flanges and Flanged Fittings[5]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise specified. The abbreviation for poly(vinylidene fluoride) is PVDF.

4. Materials

4.1 *Lining:*

4.1.1 *Material*—The lining shall be made from PVDF resins conforming to the requirements of Specification D 3222, except that a maximum of 1 % by weight of additives or colorants, or both, is permissible. Organic color-

[1] This specification is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.11 on Composite.

Wed Feb 02 02:05:36 2005

ants, if used, shall be identified in the manufacturer's specification.

4.1.2 The PVDF lining shall be made from virgin resin or clean reworked resin.

4.1.3 *Mechanical Properties*—The lining shall have a minimum tensile strength at yield of 5000 psi and a minimum elongation at yield of 8 % when tested in accordance with the requirements of Specification D 3222, except that the test specimens shall be obtained from extruded or molded PVDF liner. The minimum values for tensile strength and elongation shall apply to both the longitudinal and circumferential directions.

4.2 *Ferrous Pipe Fittings:*

4.2.1 The mechanical properties of the pipes and fittings shall conform to the requirements of the appropriate specification of 1.2 except as they are influenced by accepted methods of processing in the industry—for example, Van Stone flaring, bending, swagging, and welding. The carbon steel pipe and wrought fittings shall be welded or seamless steel, Schedule 40 or Schedule 80, except that Schedule 30 pipe may be used in 8 and 10-in. nominal size.

4.2.2 *Finish*—The interior surfaces of all housings shall be clean and free of mold burrs, rust, scale, or other protrusions that may adversely affect the integrity or performance of the lining.

4.3 *Back-Up Gaskets:*

4.3.1 *General*—Back-up gaskets shall be used to cover the pipe end and gasket face of threaded or slip-on flanges unless a full radius is provided at the end of the pipe and flange. Gaskets may also be required on fittings to provide accommodation or elimination, or both, of sharp corners that could damage the lining.

4.3.2 *Material*—Plain gaskets meeting the temperature requirements, or perforated metallic gaskets, may be used.

5. Requirements

5.1 *Dimensions:*

5.1.1 *Housing*—Housing installation dimensions are as required in the specifications listed in 1.2.

5.1.2 *Wall Thickness*—Fitting linings shall have minimum wall thickness of 3/32 in. and a uniform face thickness of not less than 3/32 in. Pipe linings shall have a minimum wall thickness of 0.050 in. and the flared radius and gasket faces shall have a uniform thickness not less than 80 % of the wall thickness.

5.1.3 *PVDF Face Diameter*—The outside diameter of the PVDF covering the gasket face of the flange or the full face of the lap-joint stub end shall not be less than the diameter specified in the following table. They shall be concentric within 1/16 in.

PVDF Face Diameter

Nominal pipe size, in.	Minimum PVDF face diameter, in.
1	1 7/8
1 1/2	2 11/16
2	3 7/16
3	4 5/8
4	5 15/16
6	8
8	10 1/16
10	12 1/4

5.1.4 *Tolerances*—Tolerances for pipe, flanges, and fittings shall be as specified in the following table. Bolt holes in both flanges on a fixed flange spool shall straddle the same center line to facilitate alignment. Finished lined (plastic face to plastic face) fabricated fittings shall conform to the nominal face-to-face, etc. as specified in ANSI B16.5 with the applicable tolerances.

Tolerances for Pipe, Flanges, and Fittings, in.

Pipe	Tolerance
Length	±1/8
Fixed flange bolt hole alignment	±1/16
Flange perpendicularity (with pipe centerline)	3/32 in./ft of diameter
Flanges and Fittings	
All dimensions	in accordance with ANSI B16.5

5.2 *Flange Construction:*

5.2.1 Screw-type flanges shall be secured in position to prevent inadvertent turning of the flange.

5.2.2 Socket-type flanges shall be fully back-welded to the pipe housing and the inside surfaces of the socket flanges shall be welded and ground smooth.

5.2.3 Slip-on flanges shall be fully back-welded.

NOTE 3—No welding shall be done on lined components.

5.2.4 Lap-joint (or Van Stone) flanged ends may be manufactured by standard forming techniques or by using fully welded stub ends or collars. Lap-joints shall not contain any cracks or buckles.

NOTE 4—The use of lap-joint flanges in a piping system may simplify alignment.

5.3 *Venting*—Each pipe and fitting have a liner thickness less than that shown in the following table shall be provided with a venting system that will release any gases between the liner and the housing and will also indicate any leakage through the liner, in the event of liner failure. Such a system may consist of a series of 1/16 to 5/32-in. diameter holes in the housings.

NOTE 5—Vent holes should not be plugged with paint, cement, etc. since this negates the intended purposes listed in 5.3.1.

Minimum Liner Thickness for Non-Vented Piping

Nominal pipe size, in.	Liner thickness, in.
1	0.100
1 1/2	0.120
2	0.130
3	0.150
4	0.160
6	0.180
8	0.180
10	0.180

5.4 *Workmanship:*

5.4.1 Pipe and fitting linings shall show no evidence of pinholes, porosity, or cracks when inspected in accordance with 5.5.2. The linings shall fit snugly inside the pipe and fitting housings. Any bulges or other obvious indication of poor contact with the housing shall be cause for rejection.

5.4.2 The gasket face of the PVDF linings shall be free of surface defects that could impair sealing effectiveness. Scratches, dents, nicks, or tool marks on the gasket surface shall not be deeper than 10 % of the wall thickness.

5.5 *Performance:*

5.5.1 *Qualification*—PVDF-lined pipe and fittings must be capable of meeting the requirements specified in Section 6.

Copyright by the ASTM International
Wed Feb 02 02:05:43 2005

5.5.2 *Inspection:*

5.5.2.1 Each lined pipe and fitting, prior to shipment, shall be subjected to a hydrostatic test or an electrostatic test, or both, as specified in 7.1 or 7.2. The test or tests to be used shall be at the option of the manufacturer, unless otherwise specified by the purchaser.

5.5.2.2 Each lined pipe and fitting shall subsequently be visually inspected prior to shipment to verify conformance to the design and dimensional requirements of 5.4.

5.5.2.3 Each lined pipe and fitting shall bear an inspection verification impression stamp on the housing to indicate compliance with the requirements of this specification.

6. Qualification Tests

6.1 *Temperature Test:*

6.1.1 Cycle representative production samples of PVDF-lined pipe and fittings in an oven from room temperature to 135 ± 3°C (275 ± 5°F) to determine the ability of the lined components to withstand heat aging and temperature cycling. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size.

6.1.2 Install companion flanges at the manufacturer's recommended torque value, and affix a thermocouple to the ferrous housing to measure the temperature. Pipe spools shall be at least 3 ft long. After 3 h in an oven at 135°C (275°F) as indicated by the thermocouple, air cool the lined components to 50°C (122°F) maximum. Repeat this test for a total of three cycles.

6.1.3 Inspect PVDF-lined pipe and fittings after each cycle for distortion or cracks in the PVDF lining. At the completion of the third cycle, subject specimens to either the hydrostatic or electrostatic test described in 7.1 or 7.2.

6.2 *Steam-Cold Water Cycling Test:*

6.2.1 Subject representative production samples of PVDF-lined pipe and fittings to steam-cold water cycling to determine the ability of the lined components to withstand rapid temperature changes. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size.

6.2.2 Assemble PVDF-lined pipe and fittings with suitable blind flanges having provision for the introduction of steam, air, or cold water, and for drainage. Install the flanges using the manufacturer's recommended torque value. Pipe spool length shall be 10 ft minimum. Mount the test specimens in such a manner as to permit complete drainage and then subject them to 100 steam-cold water cycles, each of which shall consist of the following in the sequence given:

6.2.2.1 Circulate 30 ± 2 psig saturated steam through the specimens until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen has been maintained at the maximum stabilized temperature for 30 min.

6.2.2.2 Close off steam.

6.2.2.3 Vent and introduce air to purge the specimens for a minimum of 1 min.

6.2.2.4 Circulate water at a maximum temperature of 25°C (77°F) until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen measures 50°C (122°F) maximum.

6.2.2.5 Drain, then introduce air to purge the specimens for a minimum of 1 min, making certain that specimens are completely drained.

6.2.3 There shall be no evidence of leakage from the venting system or the flanges during the 100 cycles. At the completion of the test, the liner shall show no evidence of buckling, cracking, or crazing.

6.2.4 At the conclusion of the testing specified in 6.2.2, subject the PVDF-lined pipe or fitting to the hydrostatic test specified in 7.1 or, after drying, to the electrostatic test specified in 7.2.

6.3 *Vacuum Test:*

6.3.1 Test representative production samples of PVDF-lined pipe and fittings to determine the vacuum ratings of the lined components. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size. Conduct tests at room temperature, at the manufacturer's maximum recommended service temperature, and at one intermediate temperature if a full vacuum rating cannot be achieved at the maximum recommended service temperature. Full vacuum is defined as 29.6 in. Hg corrected.

NOTE 5—Vacuum-temperature ratings should be published in the manufacturer's literature.

6.3.2 For pipe spools, specimen length shall be at least 10 pipe diameters. Install a flange incorporating a sight glass at one end and a blind flange suitable for drawing a vacuum at the other end. Make provision for measuring the ferrous housing temperature.

6.3.2.1 Heat the specimens uniformly externally with the sight glass end visible. Begin the test after the desired ferrous housing temperature has been reached. Hold a selected initial vacuum level for 24 h and if no failure occurs, increase the vacuum by 2 in. Hg. Repeat this every 24 h until failure or full vacuum is reached. Failure is defined as any buckling or collapse of the liner. If failure occurs at the initial vacuum level selected, test a new test specimen at a lower vacuum level to determine the failure threshold. The vacuum failure threshold is defined as 1 in. Hg below that at which failure occurs.

NOTE 6—The external pressure method to simulate higher than full vacuum can be used to establish the failure threshold when full vacuum is achievable. With the use of pressure taps, an external pressure is applied between the liner outside diameter and the pipe inside diameter.

6.3.3 The vacuum rating shall be 80 % of the failure threshold value.

6.3.4 At the test completion and after the vacuum rating is established, heat a duplicate specimen to the test temperature. Apply the rated vacuum to the specimen after the desired skin temperature has been reached. Achieve the rated vacuum within 2 min and apply continuously for 48 h. If no liner buckling or collapse occurs, the vacuum rating shall be considered acceptable.

6.4 *Retest*—When a test specimen fails to meet the requirements of 6.1, 6.2, or 6.3, the cause of failure shall be sought and corrected. Repeat the temperature test specified in 6.1, the steam-cold water cycling test specified in 6.2, and the vacuum test specified in 6.3, using double the number of test specimens.

7. Inspection Tests

7.1 *Hydrostatic Pressure Test*—The internal test pressure

Copyright by the ASTM International
Wed Feb 02 02:05:43 2005

shall be 425 psi minimum. Conduct the test at ambient temperature. Completely fill the pipe and fitting with clean water and bleed the system free of all air prior to the application of pressure. Reach full test pressure within 1 min and maintain for a further 3 min. Observe the pressure gage and the venting system in the test specimen throughout the test for any evidence of leakage, which shall be cause for rejection.

7.2 *Electrostatic Test*—Conduct the test with a nondestructive high-voltage tester at an output voltage of 10 kV. A visible or audible spark (or one that is both), that occurs at the probe when electrical contact is made with the housing because of a defect in the liner, shall be cause for rejection.

8. Finish

8.1 The outside surface of all lined pipe and fittings, other than stainless steel, shall be coated with a corrosion-resistant primer over a properly prepared surface.

9. Marking

9.1 Marking on the pipe and fitting shall include the following:

9.1.1 Nominal pipe size,

9.1.2 Liner material identification ("PVDF"),

9.1.3 Manufacturer's name (or trademark),

9.1.4 This ASTM designation "ASTM F 491,"

9.1.5 Length (on pipe only), and

9.1.6 Other information such as order numbers, part numbers, item numbers, etc., which shall be provided at the purchaser's request.

9.2 Pipe liner identification shall be provided on a band containing the raised letters "PVDF." One band is required on fittings and on pipe lengths up to 6 ft; two bands are required for pipe lengths over 6 ft. The band will typically be located near the flange.

10. Packaging

10.1 The gasket face of each lined pipe and each fitting shall be protected by end plates or other suitable protective means, such as individual boxing.

11. Quality Assurance

11.1 When the product is marked with this designation, F 491, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Standard Specification for Propylene and Polypropylene (PP) Plastic-Lined Ferrous Metal Pipe and Fittings[1]

This standard is issued under the fixed designation F 492; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers factory-made propylene and polypropylene (PP) plastic-lined ferrous metal pipe and fittings, primarily intended for conveying corrosive liquids and gases. Requirements for materials, workmanship, dimensions, design, construction, working pressures and temperatures, test methods, and markings are included.

NOTE 1—In this specification, propylene plastics cover those materials defined as both polypropylene plastics and propylene plastics in Definitions D 883. Both materials are identified as "PP" on the product. Note that this is at variance with Abbreviations D 1600, where PP is the abbreviation for polypropylene.

NOTE 2—This specification does not include products *coated* with PP nor does it define the suitability of PP-lined components in chemical environments.

1.2 The ferrous piping products shall meet the requirements of the relevant specifications listed in 1.2.1. Nominal sizes from ½ through 12 in. in Class 125, 150, and 300-psi are covered.

NOTE 3—The PP sealing faces may prevent achievement of the full pressure rating of the ferrous housings. For pressure limitations, the manufacturer should be consulted.

NOTE 4—Flanged fittings are not available in sizes ½ and ¾.

1.2.1 *For Ferrous Pipe:*

Title of Specification	ASTM Designation
Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless (Types E and S)	A 53
Seamless Carbon Steel Pipe for High-Temperature Service	A 106
Electric-Resistance Welded Steel Pipe	A 135
Electric-Welded Low-Carbon Steel Pipe for the Chemical Industry	A 587
Seamless and Welded Austenitic Stainless Steel Pipe	A 312
Electric-Resistance Welded Carbon and Alloy Steel Mechanical Tubing	A 513

1.2.2 *For Ferrous Flanges:*

Title of Specification	ASTM Designation
Gray Iron Castings	A 48
Forgings, Carbon Steel, for Piping Components	A 105
Gray Iron Castings for Valves, Flanges, and Pipe Fittings	A 126
Forgings, Carbon Steel, for General-Purpose Piping	A 181
Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service	A 182
Carbon-Steel Castings Suitable for Fusion Welding for High-Temperature Service (Grade WCB).	A 216
Gray Iron Castings for Pressure-Containing Parts for Temperatures Up to 650°F (345°C)	A 278
Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures (60-40-18)	A 395
Ductile Iron Castings (60-40-18, 65-45-12, 80-55-06)	A 536

1.2.3 *For Ferrous Fittings:*

Title of Specification	ASTM Designation
Gray Iron Castings	A 48
Forgings, Carbon Steel, for Piping Components	A 105
Gray Iron Castings for Valves, Flanges, and Pipe Fittings	A 126
Forgings, Carbon Steel, for General-Purpose Piping	A 181
Carbon Steel Castings Suitable for Fusion Welding for High-Temperature Service (Grade WCB)	A 216
Piping Fittings of Wrought Carbon Steel and Alloy for Moderate and Elevated Temperatures Steel Welding Fittings	A 234
Gray Iron Castings for Pressure-Containing Parts for Temperatures up to 650°F (345°C)	A 278
Austenitic Steel Castings for High-Temperature Service	A 351
Alloy Steel Castings Specially Heat-Treated for Pressure-Containing Parts Suitable for High-Temperature Service	A 389
Ductile Iron Castings (60-40-18, 64-45-12, 80-55-06)	A 536
Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures (60-40-18)	A 395
Wrought Austenitic Stainless Steel Piping Fittings	A 403

1.3 The PP-lined flanged pipe and fitting assemblies are limited to use from −18 to 107°C (0 to 225°F). For use below −18°C (0°F) consult the manufacturer. Use in specific aggressive environments may alter the above temperature range. The operating temperature limits shall be established by mutual agreement between the purchaser and the seller.

1.4 The values stated in inch-pound units are to be regarded as the standard.

2.3 *Federal Standard:*
Fed. Std. No. 123 Marking for Shipment (Civil Agencies)[6]
2.4 *Military Standard:*
MIL-STD-129 Marking for Shipment and Storage[6]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated.

4. Materials

4.1 *Lining:*

4.1.1 *Material*—The lining shall be made from PP resins conforming to the requirements of Specification D 2146, except that (*1*) a maximum of 1 % by weight of colorants is permissible for identification, and (*2*) up to 30 % by weight glass fiber filler is permissible to modify physical properties. Organic colorants, if used, shall be identified in the manufacturer's specification.

4.1.2 The PP lining shall be made from virgin resin or clean reworked resin which is not thermally degraded.

4.1.3 Two types of PP resins are covered in this specification. Type I materials are polypropylene homopolymer resins; Type II are propylene copolymer resins.

4.1.4 *Mechanical Properties*—The following table lists minimum tensile strength and minimum elongation at yield for each PP type when tested in accordance with the requirements of Specification D 2146, except that the test specimens shall be obtained from extruded or molded PP liner. The minimum values for tensile strength and elongation shall apply to both the longitudinal and circumferential directions.

Mechanical Properties of PP

PP Type	Minimum Tensile Properties at Yield	
	Strength, psi (MPa)	Elongation, %
Type I (Homopolymer)	4000 (28)	10
Type II (Copolymer)	3000 (21)	10
30 % Glass Fiber Filled	2500 (17)	2

4.1.5 *Flow Rate*—PP resins used to manufacture the PP liner and molded fittings shall have the following flow rate when tested in accordance with Condition L of Test Method D 1238.

Type I—0.2 to 0.6 g/10 min
Type II—0.3 to 0.8 g/10 min
30 % Glass Fiber Filled—3.0 to 6.0 g/10 min

The flow rate of PP linings made from Type I and Type II resins shall not exceed 1.7 g/10 min, or 1.7 times the flow rate of the original resin, whichever is smaller. The melt flow rate of PP linings made from 30 % glass filled materials shall not exceed 7.5 g/10 min, or 1.25 times the melt flow rate of the original resin, whichever is smaller.

[6] Available from Standardization Documents Order Desk, Bldg. 4 Section D, 700 Robbins Ave., Philadelphia, PA 19111-5094, Attn: NPODS.

4.2 *Ferrous Pipe and Fittings:*

4.2.1 The mechanical properties of the pipes and fittings shall conform to the requirements of the appropriate specification of 1.2 except as they are influenced by accepted methods of processing in the industry, for example, Van Stone flaring, bending, swagging, and welding. The carbon steel pipe and wrought fittings shall be welded or seamless steel, Schedule 40 or Schedule 80, except that Schedule 30 pipe may be used in 8, 10, and 12-in. nominal size. Schedule 20 may also be used for 12-in. nominal size with the agreement of the purchaser.

4.2.2 *Finish*—The interior surfaces of all housings shall be clean and free of mold burrs, rust, scale, or other protrusions that may adversely affect the integrity or performance of the lining.

4.3 *Back-Up Gaskets:*

4.3.1 *General*—Back-up gaskets shall be used to cover the pipe end and gasket face of threaded or slip-on flanges unless a full radius or chamfer is provided at the end of the pipe and flange. Gaskets may also be required on fittings to provide accommodation or elimination, or both, of sharp corners that could damage the lining.

4.3.2 *Material*—Plain gaskets meeting the temperature requirements, or perforated metallic gaskets, may be used.

5. Requirements

5.1 *Dimensions:*

5.1.1 *Housings*—Housing installation dimensions are as required in the applicable material specification listed in 1.2.

5.1.2 *Wall Thickness*—Fitting linings shall have a minimum wall thickness of 3/32 in. (24 mm), and shall have a uniform face thickness of not less than 3/32 in. (24 mm). Pipe linings shall have a minimum wall thickness of 0.050 in. (13 mm), and the flared radius and gasket faces shall have a uniform thickness not less than 80 % of the wall thickness. Molded faces shall not be less than 3/32 in. thick.

5.1.3 *PP Face Diameter*—The outside diameter of the PP covering the gasket face of the flange or the full face of the lap-joint stub end shall not be less than the diameter specified in the following table. They shall be concentric within 1/16 in.

Face Diameter

Nominal pipe size, in.	Minimum PP face diameter, in. (mm)
1	1 7/8 (48)
1 1/2	2 11/16 (68)
2	3 7/16 (87)
2 1/2	3 15/16 (100)
3	4 5/8 (119)
4	5 15/16 (151)
6	8 (203)
8	10 1/16 (256)
10	12 1/4 (311)
12	14 3/8 (365)

5.1.4 *Tolerances*—Tolerances for pipe, flanges, and fittings shall be as specified in the following table. Bolt holes in both flanges on a fixed flange spool shall straddle the same center line to facilitate alignment. Finished lined (plastic face to plastic face) fabricated fittings shall conform to the nominal face-to-face, etc., as specified in ANSI B16.1, B16.5, or B16.42 with the applicable tolerances.

Copyright by the ASTM International
Wed Feb 02 02:06:20 2005

Tolerances for Pipe, Flanges, and Fittings, in.

Pipe	Tolerance
Length	±⅛ (32 mm)
Fixed flange bolt hole alignment	±1/16 (16 mm)
Flange perpendicularity (with pipe centerline)	3/32 in./ft (80 mm/m) of diameter
Flanges and Fittings	
All dimensions	in accordance with ANSI B16.1, B16.5, or B16.42

5.2 *Flange Construction:*

5.2.1 Screw-type flanges shall be secured in position to prevent inadvertent turning of the flange.

5.2.2 Socket-type flanges shall be fully back-welded to the pipe housing and the inside surfaces of the socket flanges shall be welded and ground smooth.

5.2.3 Slip-on flanges shall be fully back-welded.

NOTE 5—No welding shall be done on lined components.

5.2.4 Lap-joint (or Van Stone) flanged ends may be manufactured by standard forming techniques or by using fully welded stub ends or collars. Lap-joints shall not contain any cracks or buckles.

NOTE 6—The use of lap-joint flanges in a piping system may simplify alignment.

5.3 *Workmanship:*

5.3.1 Pipe and fitting linings shall show no evidence of pinholes, porosity, or cracks when inspected in accordance with 5.4.2. The linings shall fit snugly inside the pipe and fitting housings. Any bulges or other obvious indication of poor contact with the housing shall be cause for rejection.

5.3.2 The gasket face portion of the linings shall be free of surface defects that could impair sealing effectiveness. Scratches, dents, nicks, or tool marks on the gasket surface shall not be deeper than 10 % of the wall thickness.

5.4 *Performance:*

5.4.1 *Qualification*—The lined pipes and fittings must be capable of meeting the requirements specified in Section 6.

5.4.2 *Inspection:*

5.4.2.1 Each lined pipe and fitting, prior to shipment, shall be subjected to a hydrostatic test or electrostatic test, or both, as specified in 7.1 or 7.2. The test or tests to be used shall be at the option of the manufacturer, unless otherwise specified by the purchaser.

5.4.2.2 Each lined pipe and fitting shall subsequently be visually inspected prior to shipment to verify conformance to the design and dimensional requirements of 5.3.

5.4.2.3 Each lined pipe and fitting shall bear an inspection verification impression stamp on the housing to indicate compliance with the requirements of this specification.

6. Qualification Tests

6.1 *Temperature Test:*

6.1.1 Cycle representative production samples of the lined pipes and fittings in an oven from room temperature to 225 ± 5°F (107 ± 3°C) to determine the ability of the lined components to withstand heat aging and temperature cycling. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size.

6.1.2 Install companion flanges at the manufacturer's recommended torque value, and affix a thermocouple to the ferrous housing to measure the temperature. Pipe spools shall be at least 3 ft (1 m) long. After 3 h in an oven at 225 ± 5°F (107 ± 3°C) as indicated by the thermocouple, air cool the lined components to 85°F (29°C) maximum. Repeat this test for a total of three cycles.

6.1.3 Inspect the lined pipe and fittings after each cycle for distortion or cracks in the lining. At the completion of the third cycle, subject specimens to either the hydrostatic or electrostatic test described in 7.1 or 7.2.

6.2 *Steam-Cold Water Cycling Test:*

6.2.1 Subject representative production samples of the lined pipe and fittings to steam-cold water cycling to determine the ability of the lined components to withstand rapid temperature changes. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size.

6.2.2 Assemble the lined pipe and fittings with suitable blind flanges having provision for the introduction of steam, air, or cold water, and for drainage. Install the flanges using the manufacturer's recommended torque value. Pipe spool length shall be 10 ft (3 m) minimum. Mount the test specimens in such a manner as to permit complete drainage and then subject them to 100 steam-cold water cycles, each of which shall consist of the following in the sequence given:

6.2.2.1 Circulate 4 ± 1-psig (28 ± 7-kPa) saturated steam through the specimens until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen has been maintained at the maximum stabilized temperature for 30 min.

6.2.2.2 Close off steam.

6.2.2.3 Vent and introduce air to purge the specimens for a minimum of 1 min.

6.2.2.4 Circulate water at a maximum temperature of 77°F (25°C). Circulate the cooling water until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen measures 100°F (38°C) maximum.

6.2.2.5 Drain and introduce air to purge the specimens for a minimum of 1 min, making certain that specimens are completely drained.

6.2.3 There shall be no evidence of leakage from the venting system or the flanges during the 100 cycles. At the completion of the test, the liner shall show no evidence of buckling, cracking, or crazing.

6.2.4 At the conclusion of the testing specified in 6.2.2, subject the lined pipe or fitting to the hydrostatic test specified in 7.1 or, after drying, to the electrostatic test specified in 7.2.

6.3 *Vacuum Test:*

6.3.1 Test representative production samples of the lined pipe and fittings to determine the vacuum ratings of the lined components. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size. Conduct tests at room temperature and at the manufacturer's maximum recommended service temperature.

NOTE 7—Vacuum-temperature ratings should be published in the manufacturer's literature.

6.3.2 For pipe spools, specimen length shall be at least 10 pipe diameters. Install a flange incorporating a sight glass at one end and a blind flange suitable for drawing a vacuum at the other end. Make provisions for measuring the ferrous housing temperature. Heat the specimens uniformly externally with the sight glass end visible, and after the desired ferrous housing temperature is reached, begin the test. Hold a selected initial vacuum level for 24 h and if no failure occurs, increase the vacuum by 2 in. Hg (6.7 kPa). Repeat

Copyright by the ASTM International
Wed Feb 02 02:06:21 2005

every 24 h until failure or full vacuum is reached. Failure is defined as any buckling or collapse of the liner. Full vacuum is defined as 29.6 in. Hg (100 kPa) corrected. If failure occurs at the initial vacuum level selected, test a new test specimen at a lower vacuum level to determine the failure threshold. The vacuum failure threshold is defined as 1 in. Hg (3.4 kPa) below that at which failure occurs.

NOTE 8—The external pressure method to simulate higher than full vacuum can be used to establish the failure threshold when full vacuum is achievable. With the use of pressure taps, an external pressure is applied between the liner outside diameter and the pipe inside diameter.

6.3.3 The vacuum rating shall be 80 % of the failure threshold value.

6.3.4 At the test completion and after the vacuum rating is established, heat a duplicate specimen to the test temperature. Apply the rated vacuum to the specimen after the desired skin temperature has been reached. Achieve the rated vacuum within 2 min and apply continuously for 48 h. If no liner buckling or collapse occurs, the vacuum rating shall be considered acceptable.

6.4 *Retest*—When a test specimen fails to meet the requirements of 6.1, 6.2, or 6.3, the cause of failure shall be sought and corrected. Repeat the temperature test specified in 6.1, the steam-cold water cycling test specified in 6.2, and the vacuum test specified in 6.3, using double the number of test specimens.

7. Inspection Tests

7.1 *Hydrostatic Pressure Test*—The internal test pressure shall be 250 psi (1.7 MPa) minimum for 125-psi (0.9-MPa) components and 425 psi (2.9 MPa) minimum for 150-psi (0.1-MPa) and 300-psi (2.1-MPa) components. Conduct the test at ambient temperature. Completely fill the pipe and fitting with clean water and bleed the system free of all air prior to the application of pressure. Reach full test pressure within 1 min and maintain for a further 3 min. Observe the pressure gage throughout the test for any evidence of leakage, which shall be cause for rejection.

7.2 *Electrostatic Test*—Conduct the test with a nondestructive high voltage tester at an output voltage of 10 kV. A visible or audible spark, or one that is both, that occurs at the probe when electrical contact is made with the housing because of a defect in the liner shall be cause for rejection.

8. Finish

8.1 The outside surface of all lined pipe and fittings, other than stainless steel, shall be coated with a corrosion-resistant coating over a properly prepared surface.

NOTE 9—Industry practice is to use a paint primer (generally either zinc-rich or epoxy bonded) which permits the user to apply a second layer of paint consistent with his color scheme or identification code, if he so desires.

9. Marking

9.1 Marking on the pipe and fitting shall include the following:

9.1.1 Nominal pipe size,

9.1.2 Liner material identification "PP,"

9.1.3 Manufacturer's name (or trademark),

9.1.4 This ASTM specification "ASTM F 492,"

9.1.5 Length (on pipe only), and

9.1.6 Other information such as order numbers, part numbers, item numbers, etc. shall be provided at the purchaser's request.

9.2 Pipe liner identification shall be provided on a band containing the raised letters "PP." One band is required on fittings and on pipe lengths up to 6 ft; two bands are required for pipe lengths over 6 ft. The band will typically be located near the flange.

10. Packaging

10.1 The gasket face of each lined pipe and each fitting shall be protected by end plates or other suitable protective means, such as individual boxing.

11. Quality Assurance

11.1 When the product is marked with this designation, F 492, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

Copyright by the ASTM International

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to federal/military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless the purchaser disapproves. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. federal contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the materials shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2.1—The inclusion of U.S. Government procurement requirements should not be construed as an indication that the U.S. Government uses or endorses the products described in this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Standard Specification for Poly(Vinylidene Chloride) (PVDC) Plastic-Lined Ferrous Metal Pipe and Fittings[1]

This standard is issued under the fixed designation F 599; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers factory-made poly(vinylidene chloride) (PVDC) plastic-lined ferrous metal pipe and fittings primarily intended for conveying corrosive liquids and gases. Requirements for materials, workmanship, dimensions, construction, working pressure and temperatures, test methods, and markings are included.

NOTE 1—This specification does not include products *coated* with PVDC nor does it define the suitability of PVDC-lined components in chemical environments.

1.2 The values given in parentheses are provided for information purposes only.

1.3 The ferrous piping products shall meet the requirements of the relevant specifications listed in 1.3.1, 1.3.2, and 1.3.3. Nominal sizes from 1 through 8 in. in 125, 150, and 300 psi ratings are covered.

NOTE 2—The PVDC sealing faces may prevent achievement of the full pressure rating of the ferrous housing. For pressure limitations, the manufacturer should be consulted.

1.3.1 *For Ferrous Pipe:*

Title of Specification	ASTM Designation
Pipe, Steel, Black, and Hot-Dipped, Zinc-Coated, Welded and Seamless	A 53
Seamless Carbon Steel Pipe for High-Temperature Service	A 106
Electric-Resistance-Welded-Carbon and Alloy Steel Mechanical Tubing.	A 513
Electric-Resistance-Welded Steel Pipe	A 135
Electric-Welded Low-Carbon Steel Pipe for the Chemical Industry	A 587

1.3.2 *For Ferrous Flanges:*

Title of Specification	ASTM Designation
Gray Iron Castings	A 48
Forgings, Carbon Steel for Piping Components	A 105
Gray Iron Castings for Valves, Flanges, and Pipe Fittings	A 126
Forgings, Carbon Steel for General Purpose Piping	A 181
Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service	A 182
Carbon-Steel Castings Suitable for Fusion Welding for High-Temperature Service	A 216
Gray Iron Castings for Pressure-Containing Parts for Temperatures up to 650°F (345°C)	A 278
Ferritic Ductile Iron Pressure-Retaining Castings for Use At Elevated Temperatures	A 395
Ductile Iron Castings	A 536

1.3.3 *For Ferrous Fittings:*

Title of Specification	ASTM Designation
Gray Iron Castings	A 48
Forgings, Carbon Steel for Piping Components	A 105
Gray Iron Castings for Valves, Flanges and Pipe Fittings	A 126
Forgings, Carbon Steel, for General Purpose Piping	A 181
Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service	A 182
Carbon-Steel Castings Suitable for Fusion Welding for High-Temperature Service	A 216
Piping Fittings of Wrought Carbon Steel and Alloy Steel for Moderate and Elevated Temperatures	A 234
Gray Iron Castings for Pressure-Containing Parts for Temperatures up to 650°F (345°C)	A 278
Alloy Steel Castings Specially Heat-Treated for Pressure-Containing Parts Suitable for High-Temperature Service	A 389
Ferritic Ductile Iron Pressure-Retaining Castings for Use at Elevated Temperatures	A 395
Wrought Austenitic Stainless Steel Piping Fittings	A 403

1.4 The PVDC-lined pipe and fitting assemblies are limited to use from −18 to 79°C (0 to 175°F). For use below −18°C (0°F) consult the manufacturer. Use in specific aggressive environments may alter the above temperature range. The operating temperature range shall be established by mutual agreement between consumer and producer.

NOTE 3—Storage or handling below −7°C (20°F) of uninstalled 4, 6, and 8-in. lined pipe should be avoided.

B16.5 Steel Pipe Flanges and Flanged Fittings[4]

3. Terminology

3.1 The terminology used is in accordance with Terminology F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise specified.

[1] This specification is under the jurisdiction of ASTM Committee F-17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.11 on Composite.

Current edition approved Sept. 10, 1995. Published November 1995. Originally published as F 599 – 78. Last previous edition F 599 – 93.

3.2 The abbreviation for poly(vinylidene chloride) is PVDC.

4. Materials

4.1 *Lining:*

4.1.1 *Material*—The lining shall be made from PVDC compounds conforming to the requirements of Specification D 729, except that up to a 20 weight % glass fiber filler is used to modify physical properties, and a maximum of 1 weight % of colorant is permissible for identification. Organic colorants, if used, shall be identified in the manufacturer's specification.

4.1.2 The PVDC shall be virgin compound or clean reworked compound.

4.1.3 *Mechanical Properties*—The minimum tensile strength and minimum elongation at yield when tested in accordance with Specification D 729 shall be 1500 psi (10.34 MPa) and 2 % respectively. The minimum values for tensile strength and elongation shall apply to both the longitudinal and circumferential directions.

4.1.4 *Specific Gravity*—The linings manufactured from PVDC resins with 20 % glass fibers shall have a relative density of 1.8 to 1.9 when tested in accordance with the requirements of Test Methods D 792 and D 1505.

4.2 *Ferrous Pipe and Fittings:*

4.2.1 *Mechanical Properties*—The mechanical properties of the pipe and fittings shall conform to the requirements of the appropriate specification of 1.3 except as they are influenced by accepted methods of processing in the industry, for example, Van Stone flaring, bending, swaging, and welding. The carbon steel pipe and wrought fittings shall be welded or seamless steel, Schedule 40 or Schedule 80, except that Schedule 30 pipe may be used in 8-in. nominal size.

4.2.2 *Finish*—The interior surfaces of all housings shall be clean and free of mold burrs, rust, scale, or other protrusions which may adversely affect integrity or performance of the lining.

4.3 *Back-Up Gaskets:*

4.3.1 *General*—Back-up gaskets shall be used to cover the pipe end and gasket face of threaded or slip-on flanges unless a full radius or chamfer is provided at the end of the pipe and flange. Gaskets may also be required on fittings to provide accommodation or elimination, or both, of sharp corners which could damage the lining.

4.3.2 *Material*—Plain gaskets meeting the temperature requirements, or perforated metallic gaskets, may be used.

5. Requirements

5.1 *Dimensions:*

5.1.1 *Housings*—Housing installation dimensions are as required in the applicable material specification listed in 1.3.

5.1.2 *Wall Thickness*—Fitting linings shall have a minimum wall thickness of 3/32 in. (2.4 mm), and shall have a uniform face thickness of not less than 3/32 in. Pipe linings shall have a minimum wall thickness of 3/32 in., and the flared radius and gasket faces shall have a uniform thickness of not less than 80 % of the wall thickness. Molded faces shall not be less than 3/32 in. thick.

5.1.3 *PVDC Face Diameter*—The outside diameter of the PVDC covering the gasket face of the flange or the full face of the lap-joint stub end shall not be less than the diameter specified in Table 1. They shall be concentric within 1/16 in. (1.6 mm).

5.1.4 *Tolerances*—Tolerance for pipe, flanges, and fittings shall be as specified in Table 2. Bolt holes in both flanges on a fixed spool shall straddle the same center line to facilitate alignment. Finish lined (plastic face to plastic face) fabricated fittings shall conform to the nominal face-to-face, etc., as specified in ANSI B16.1 or B16.5 with the applicable tolerances.

5.2 *Flange Construction:*

5.2.1 Screw-type flanges shall be secured in position to prevent inadvertent turning of the flange.

5.2.2 Socket-type flange shall be fully back-welded to the pipe housing and the inside surfaces of the socket flanges shall be welded and ground smooth.

5.2.3 Slip-on flanges shall be fully back-welded.

NOTE 4—No welding shall be done on lined components.

5.2.4 Lap-joint (or Van Stone) flanged ends may be manufactured by standard forming techniques or by using fully welded stub ends or collars. Lap-joints shall not contain any cracks or buckles.

NOTE 5—The use of lap-joint flanges in a piping system may simplify alignment.

5.3 *Workmanship:*

5.3.1 Pipe and fitting linings shall show no evidence of pinholes, porosity, or cracks when inspected in accordance with 5.4.2. The lining shall fit snugly inside the pipe and fitting housings. Any bulges or other obvious indication of poor contact with the housing shall be cause for rejection.

5.3.2 The gasket face portion of the PVDC linings shall be free of surface defects that could impair sealing effectiveness. Scratches, dents, nicks, or tool marks on the gasket surface shall not be deeper than 10 % of the wall thickness.

5.4 *Performance:*

5.4.1 *Qualification*—PVDC-lined pipe and fittings must be capable of meeting the requirements specified in Section 6.

5.4.2 *Inspection:*

5.4.2.1 Each lined pipe and fitting, prior to shipment, shall be subjected to a hydrostatic test or an electrostatic test,

TABLE 1 PVDC Face Diameter

Nominal Pipe Size, in.	Minimum PVDC Face Diameter, in. (mm)
1	1 7/8 (47.62)
1.5	2 11/16 (68.26)
2	3 7/16 (87.31)
2.5	3 15/16 (104.01)
3	4 5/8 (117.48)
4	5 15/16 (150.81)
6	8 (203.20)
8	10 1/16 (255.59)

TABLE 2 Tolerances for Pipe, Flanges, and Fittings

	Tolerance, in. (mm)
Pipe:	
Length	±1/8 (±3)
Fixed flange bolt hole alignment	±1/16 (±1.6)
Flange perpendicularity (with pipe centerline)	3/32 in./ft (2.38 mm/m) of diameter
Flanges and Fittings:	
All dimensions	per ANSI B16.1 or ANSI B16.5

or both, as specified in 7.1 or 7.2. The test or tests to be used shall be at the option of the manufacturer, unless otherwise specified by the purchaser.

5.4.2.2 Each lined pipe and fitting shall subsequently be visually inspected prior to shipment to verify conformance to the design and dimensional requirements of 5.3.

5.4.2.3 Each lined pipe and fitting shall bear an inspection verification impression stamp on the housing to indicate compliance with the requirements of this specification.

6. Qualification Tests

6.1 *Temperature Test:*

6.1.1 Representative production samples of PVDC-lined pipe and fittings shall be cycled in an oven from room temperature to 79 ± 3°C (175 ± 5°F) to determine the ability of the lined components to withstand heat aging and temperature cycling. A minimum of two pipe spools, tees, and 90-deg elbows shall be tested in each size.

6.1.2 Install companion flanges at the manufacturer's recommended torque value, and affix a thermocouple to the ferrous housing to measure the temperature. Pipe spools shall be at least 3-ft (0.9-m) long. After 3 h in an oven at 79°C (175°F) as indicated by the thermocouple, air cool the lined components to 29°C (85°F) maximum. Repeat this test for a total of three cycles.

6.1.3 Inspect the PVDC-lined pipe and fittings after each cycle for distortion or cracks in the lining. At the completion of the third cycle, subject specimens to either the hydrostatic or electrostatic test described in 7.1 or 7.2.

6.2 *Thermo Cycling Test:*

6.2.1 Subject representative production samples of PVDC-lined pipe and fittings to hot water-cold water cycling to determine the ability of the lined components to withstand rapid temperature changes. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size.

6.2.2 Assemble the PVDC-lined pipe and fittings with suitable-blind flanges having provision for the introduction of air, hot and cold water, and drainage. Install the flanges using the manufacturer's recommended torque value. Pipe-spool length shall be 10 ft (3 m) minimum. Mount the test specimens in such a manner as to permit complete drainage and then subject them to 100 hot water-cold water cycles, each of which shall consist of the following in the sequence given:

6.2.2.1 Circulate 79 ± 3°C (175 ± 5°F) water through the specimens until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen has been maintained at the maximum stabilized temperature for 30 min.

6.2.2.2 Close off hot water.

6.2.2.3 Drain and introduce air to purge the specimens for a minimum of 1 min.

6.2.2.4 Circulate water at a maximum temperature of 25°C (77°F). Circulate the cooling water until the ferrous housing-skin temperature adjacent to the flange at the outlet end of the test specimen measures 38°C (100°F) maximum.

6.2.2.5 Drain and introduce air to purge the specimens for a minimum of 1 min, making certain that specimens are completely drained.

6.2.3 There shall be no evidence of leakage from the flanges during the 100 cycles. At the completion of the test, the liner shall show no evidence of buckling, cracking, or crazing.

6.2.4 At the conclusion of the testing specified in 6.2.2, the lined pipe or fitting shall be subjected to the hydrostatic test specified in 7.1, or, after drying, to the electrostatic test specified in 7.2.

6.3 *Vacuum Testing:*

6.3.1 Test representative production samples of the PVDC-lined pipe and fittings to determine the vacuum ratings of the lined components. Test a minimum of two pipe spools, tees, and 90-deg elbows in each size. Conduct tests at room temperature and at the manufacturer's-maximum recommended service temperature.

NOTE 6—Vacuum-temperature ratings should be published in the manufacturer's literature.

6.3.2 For pipe spools, specimen length shall be at least ten pipe diameters. Install a flange incorporating a sight glass at one end and a blind flange suitable for drawing a vacuum at the other end. Make provisions for measuring the ferrous housing temperature. Heat the specimens uniformly externally with the sight-glass end visible, and after the specified ferrous housing temperature is reached, begin the test. Hold a selected initial vacuum level for 8 h, and if no failure occurs, increase the vacuum by 2 in. Hg (6.8 kPa). Repeat every 8 h until full vacuum is reached. Failure is defined as any buckling or collapse of the liner. Full vacuum is defined as 29.6 in. Hg (100 kPa) corrected (a gage pressure of −100 kPa). If failure occurs at the initial-vacuum level selected, test a new specimen at a lower-vacuum level to determine the failure threshold. The vacuum-failure threshold is defined as 1 in. Hg (3.4 kPa) below that at which failure occurs.

NOTE 7—The external-pressure method to simulate higher than full vacuum can be used to establish the failure threshold when full vacuum is achievable. With the use of pressure taps, an external pressure is applied between the liner outside diameter and the pipe inside diameter.

6.3.3 The vacuum rating shall be 80 % of the failure threshold value.

6.3.4 At the test (6.3.2) completion, and after the vacuum rating (6.3.3) is established, heat a duplicate specimen to the specified test temperature. Apply the rated vacuum to the specimen after the specified-skin temperature has been reached. Achieve the rated vacuum within 2 min, and apply continuously for 48 h. If no liner buckling or collapse occurs, the vacuum rating shall be considered acceptable.

6.4 *Retest*—When a test specimen fails to meet the requirements of 6.1, 6.2, or 6.3, the cause of failure shall be sought and corrected. Repeat the temperature test specified in 6.1, the hot water-cold water cycling test specified in 6.2, and the vacuum test specified in 6.3, using double the number of test specimens.

7. Inspection Tests

7.1 *Hydrostatic-Pressure Test*—The internal test pressure shall be 250 psi (1720 kPa) minimum for 125-psi (862-kPa) components and 425 psi (2930 kPa) for 150-psi and 300-psi components. Conduct the test at ambient temperature. Completely fill the pipe and fitting with clean water and bleed the system free of all air prior to application of pressure. Reach full test pressure within 1 min and maintain for a further 3 min. Observe the pressure gage and test

Copyright by the ASTM International
Wed Feb 02 02:06:53 2005

specimen, throughout the test for any evidence of leakage which shall be cause for rejection.

7.2 *Electrostatic Test*—Conduct the test with a nondestructive high-voltage tester at an output voltage of 10 kV. A visible or audible spark, or both, that occurs at the probe when electrical contact is made with the housing because of a defect in the liner, shall be cause for rejection.

8. Finish

8.1 The outside surface of all lined pipe and fittings, other than stainless steel, shall be coated with a corrosion-resistant primer over a properly prepared surface.

9. Marking

9.1 Marking on pipe and fittings shall include the following:

9.1.1 Nominal pipe size,

9.1.2 Liner material identification (PVDC),

9.1.3 Manufacturer's name (or trademark),

9.1.4 This designation "ASTM F 599,"

9.1.5 Length (on pipe only), and

9.1.6. Other information such as order numbers, part numbers, item numbers, etc., at the purchaser's request.

9.2 Pipe-liner identification shall be provided on a band containing the raised letters "PVDC". One band is required on fittings and on pipe lengths up to 6 ft (2 m); two bands are required for pipe lengths over 6 ft. The band will typically be located near the flange.

10. Packaging

10.1 The gasket face of each lined pipe and fitting shall be protected by end plates or other suitable protective means, such as individual boxing.

11. Quality Assurance

11.1 When the product is marked with this designation, F 599, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Designation: F 628 – 01

An American National Standard

Standard Specification for Acrylonitrile-Butadiene-Styrene (ABS) Schedule 40 Plastic Drain, Waste, and Vent Pipe With a Cellular Core[1]

This standard is issued under the fixed designation F 628; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers coextruded acrylonitrile-butadiene-styrene (ABS) plastic drain, waste, and vent pipe made to Schedule 40 iron pipe sizes (IPS) and produced by the coextrusion process with concentric inner and outer solid ABS layers and the core consisting of closed-cell cellular ABS. Plastic which does not meet the material requirements specified in Section 5 is excluded from single layer and all coextruded layers.

1.2 Fittings suitable for use with pipe meeting the requirements of this specification are given in Annex A1. Fittings meeting the requirement of Specification D 2661 are also acceptable.

1.3 Acrylonitrile-butadiene-styrene plastic which does not meet the definitions of virgin ABS plastic as given in 3.2.4 is excluded, as performance of plastic other than those defined as virgin was not determined. ABS rework plastic which meets the requirements of rework plastic as given in 5.3 is acceptable.

1.4 Reprocessed plastic or recycled plastic as defined in Terminology D 883 is excluded.

1.5 Recommendations for storage, joining, and installation are provided in Appendixes X1, X2, and X3, respectively.

1.6 The text of this specification references notes, footnotes, and appendixes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

1.7 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

3.1.1 *cellular plastic*—a plastic containing numerous cells, intentionally introduced, interconnecting or not, distributed throughout the mass.

3.1.2 *closed-cell cellular plastic*—cellular plastic in which almost all the cells are noninterconnecting.

3.1.3 *coextruded pipe*—pipe consisting of two or more concentric layers of material bonded together in processing by any combination of temperature, pressure, grafting, crosslinking, or adhesion.

3.1.4 *coextrusion*—a process whereby two or more heated or unheated plastic material streams forced through one or more shaping orifice(s) become one continuously formed piece.

3.1.5 *room temperature*—a temperature in the range from 68 to 85 ± 3.6°F (20 to 30 ± 2°C).

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *lot*—a lot shall consist of all pipe produced, of one size, from one extrusion line, during one designated 24-h period.

3.2.2 *recycled plastic*—a plastic prepared from discarded articles that have been cleaned and reground.

3.2.3 *reprocessed plastic*—a thermoplastic prepared from usually melt processed scrap or reject parts by a plastics processor, or from nonstandard or nonuniform virgin material.

3.2.4 *virgin ABS plastic*—plastic in the form of pellets, granules, powder, floc, or liquid that has not been subjected to use or processing other than that required for its initial manufacture.

4. Classification

4.1 Pipe produced in accordance with this specification is intended to provide pipe suitable for the drainage and venting of sewage and certain other liquid wastes.

NOTE 1—Before installing pipe for waste disposal use, the approval of the cognizant building code authority should be obtained as conditions not commonly found in normal use may be encountered and temperatures in excess of 180°F (82°C) may be encountered.

5. Materials

5.1 *Material Specification*—Virgin ABS plastic shall conform to the requirements prescribed in Specification D 3965 with a cell classification of 4-2-2-2-2. The color and form of the material shall be as agreed upon between the seller and the purchaser in accordance with Specification D 3965.

5.2 The ABS plastic shall conform to the following requirements:

5.2.1 *Acrylonitrile-Butadiene-Styrene (ABS) Plastic*—Plastic shall contain a minimum of 15 % acrylonitrile, 6 % butadiene, and 15 % styrene or substituted styrene, or both, of polymers or blends of polymers.

5.2.2 ABS plastic shall contain no more than 10 % of other monomeric or polymeric components plus other necessary compounding ingredients.

5.3 *Rework Material*—The manufacturer shall use only his own clean rework pipe material conforming with these cell class requirements. Use it only in the core layer. The pipe produced shall meet all the requirements of this specification.

6. Requirements

6.1 *General*—The pipe and fittings should be homogeneous throughout and free of visible cracks, holes, foreign inclusions, or other injurious defects. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

6.1.1 The requirements in this section are intended only for use as quality control tests, not as simulated service tests.

6.2 *Dimension and Tolerance*:

6.2.1 *Outside Diameter*—The outside diameter and tolerances shall meet the requirements of Table 1 when measured in accordance with Test Method D 2122. The tolerances for out-of-roundness shall apply to pipe prior to shipment.

6.2.2 *Wall Thickness*—The wall thickness and tolerances shall meet the requirements of Table 2 when measured in accordance with Test Method D 2122.

6.2.3 *Length*—The pipe shall be in either 10 or 20-ft (3.05 or 6.1-m) lengths, unless otherwise specified. The allowable tolerance on length shall be +½, –0 in. (+12, –0 mm).

6.3 *Performance Requirements*:

6.3.1 *Pipe Stiffness*—The minimum pipe stiffness values at 5 % deflection when measured in accordance with Test Method D 2412, shall equal or exceed the values in Table 3. The rate of crosshead motion shall be 0.20 to 0.25 in./min (5.1 to 6.3 mm/min). Three specimens shall be tested. If all three meet this requirement, the sample meets this requirement. If one or two fail, additional testing shall be conducted in accordance with 6.3.1.1. If all three fail, the sample does not meet the requirement.

6.3.1.1 *Pipe Stiffness and Lower Confidence Limit*—In the event that one or two of the specimens tested in 6.3.1 fail to meet the minimum requirement, the average pipe stiffness of eleven specimens shall meet or exceed the minimum requirement given in Table 3. The 99 % lower confidence limit (LCL)

TABLE 1 Outside Diameters and Tolerances for ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe Produced by the Coextrusion Process with Concentric Inner and Outer Solid ABS-Layers and the Core Consisting of Closed-Cell Cellular ABS

Nominal Pipe Size, in.	Outside Diameter		
	Average, in. (mm)	Tolerance on Average, in. (mm)	Out-of-Roundness Maximum Diameter Minus Minimum Diameter, in. (mm)[A]
1¼	1.660 (42.16)	+0.010, –0.000 (+0.25, –0.00)	0.024 (0.60)
1½	1.900 (48.26)	+0.010, –0.000 (+0.25, –0.00)	0.024 (0.60)
2	2.375 (60.32)	+0.010, –0.000 (+0.25, –0.00)	0.024 (0.60)
3	3.500 (88.90)	+0.015, –0.000 (+0.38, –0.00)	0.030 (0.76)

TABLE 2 Wall Thickness and Tolerance for ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe Produced by the Coextrusion Process with Concentric Inner and Outer Solid ABS Layers and the Core Consisting of Closed-Cell Cellular ABS

Nominal Pipe Size, in.	Wall Thickness[A]	
	Minimum Total Wall, in. (mm)	Tolerance, in. (mm)
1¼	0.140 (3.56)	+0.020 (+0.50)
1½	0.145 (3.68)	+0.020 (+0.50)
2	0.154 (3.91)	+0.020 (+0.50)
3	0.216 (5.42)	+0.026 (+0.66)
4	0.237 (6.02)	+0.028 (+0.71)
6	0.280 (7.11)	+0.034 (+0.86)

[A] The minimum is the lowest wall thickness of the pipe at any cross section.

TABLE 3 Pipe Stiffness of ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe Produced by the Coextrusion Process with Concentric Inner and Outer Solid ABS Layers and the Core Consisting of Closed-Cell Cellular ABS

Nominal Pipe Size, in.	Minimum Pipe Stiffness at 5 % Deflection	
	psi	(MPa)
1¼	600	(4.13)
1½	535	(3.69)
2	300	(2.06)
3	280	(1.93)
4	175	(1.21)
6	75	(0.52)

shall be within 15 % of the average value. The LCL shall be calculated using the Student's "*t*" distribution, with *N*-1 degrees of freedom, where *N* is the number of specimens. The critical *t* value shall be used to at least three significant digits. Alternatively, if the LCL exceeds the minimum pipe stiffness requirement in Table 3, but is not within 15 % of the average, the sample meets the requirements of the Pipe Stiffness testing. The eleven specimens include the three tested under 6.3.1, and an additional eight with rotation by 35°, as specified in Test Method D 2412, continuing throughout the remaining specimens.

6.3.1.2 The LCL based on testing eleven specimens is calculated as follows:

$$\text{LCL} = (\text{avg PS}) - \{2.76(\text{std. dev.})/\sqrt{(N)}\}$$

where:

$$(\text{avg PS}) = [\Sigma(\text{PS}_i)]/(11) \quad (1)$$

$$(\text{std. dev.}) = \left[\frac{\Sigma\,\text{PS}^2 - (\Sigma\text{PS})^2/N}{N-1}\right]^{1/2}$$

$$N = 11.$$

6.3.1.3 The 15 % requirement is calculated as follows:

$$(\text{avg} - \text{LCL})/(\text{avg}) \times 100 \leq 15\ \%$$

NOTE 2—For quality control testing, a single specimen may be used with the thinnest wall at the top.

NOTE 3—The 5 % deflection criterion, which was arbitrarily selected for testing convenience, should not be considered as a limitation with respect to in-use deflection. The engineer is responsible for establishing the acceptable deflection limit.

NOTE 4—The strength and load-carrying capabilities of plastic pipe are measured and reported as pipe stiffness, which is determined in accordance with Test Method D 2412. The term "crush strength" is not applicable to plastic piping because the values obtained can be significantly different, depending on the bedding, loading, or testing technique used, and the term derives from rigid pipe and refers to its ultimate strength at rupture.

6.3.2 *Pipe Flattening*—There shall be no evidence of rupture when pipe is deflected 25 % of the initial inside diameter when tested in accordance with Test Method D 2412. Three specimens shall be tested; all shall meet the requirements. Failure shall be a crack or break extending entirely through the pipe wall visible to the unaided eye.

6.3.3 *Impact Strength*—The minimum impact resistance, when tested at the time of manufacture, shall comply with Table 4. Test in accordance with Test Method D2444 using Tup A and Holder B. Use 12–lb (5 kg) tup for testing pipe sizes 4 in. and smaller and a 20–lb (10–kg) tup for sizes larger than 4 in.

6.3.3.1 Test 10 specimens. When 9 or 10 specimens pass, accept the lot. When 2 or more specimens fail, test 10 additional specimens. When 17 of 20 specimens tested pass, accept the lot. When 4 or more of 20 specimens fail, test 20 additional specimens. When 32 of 40 specimens pass, accept the lot. When 9 or more of 40 specimens fail, the lot does not meet the requirements of this specification.

6.3.3.2 Failure of the test specimen shall be shattering or any crack or break extending entirely through the pipe wall and visible to the unaided eye.

6.3.4 *Bond*—The bond between layers shall be strong and uniform. It shall not be possible to separate any two layers with a probe or point of a knife blade so that the layers separate cleanly, or so the probe or knife blade moves freely between the layers; nor shall separation of bond occur between layers during testing performed under the requirements of this specification.

6.3.5 *Pigments or Screening Agents*—The ABS compound used in the outer layer shall contain pigments or screening agents to provide protection against UV radiation.

6.4 *Other Requirements*:

6.4.1 *Inspection*—Inspection shall be made prior to installation of all pipe. Pipe that does not meet the requirements of 6.1 shall be returned to the seller.

6.4.2 *Joining*—Coextruded ABS Schedule 40 drain, waste, and vent pipe with a cellular core are joined using molded

TABLE 4 Impact Resistance of ABS Schedule 40 Plastic Drain, Waste, and Vent Pipe Produced by the Coextrusion Process and Concentric Inner and Outer Solid ABS Layers and the Core Consisting of Closed-Cell Cellular ABS

fittings meeting the requirements of Specifications D 2661 and D 3311 or the requirements for fittings listed in the Annex of this specification.

6.4.3 *Solvent Cement*—In the assembly of solvent cement joints, the safety requirements of Practice F 402 shall be followed using solvent cement meeting the requirements of Specification D 2235.

7. Sampling and Conditioning

7.1 *Sampling*—For the purpose of testing, the lot shall consist of all pipe produced of one size, from one extrusion line, during one designated 24-h period. The number of specimens designated for each test shall be taken from pipe selected at random from each lot in accordance with the random sampling plan of Practice D 1898.

NOTE 5—Also see Practices E 105 and E 122.

7.2 *Number of Test for Quality Control*— When evaluating a product against this specification, the following minimum number of specimens shall be tested for each lot.

7.2.1 *Outside Diameter*—One specimen per extrusion line.

7.2.2 *Wall Thickness*—One specimen per extrusion line.

7.2.3 *Length*—One specimen per extrusion line.

7.2.4 *Pipe Stiffness*—A minimum of three specimens per extrusion line.

7.2.5 *Pipe Flattening*—A minimum of three specimens per extrusion line.

7.2.6 *Impact Strength*—A minimum of 10 specimens and a maximum of 40.

7.2.7 *Bond*—One specimen per extrusion line.

7.3 *Conditioning* :

7.3.1 For referee testing at 73°F, condition the specimens prior to the test at 73.4 ± 3.6° (23 ± 2°C) and 50 ± 5 % relative humditity in accordance with Practice D 618, Procedure A.

7.3.2 For routine quality control testing at 73°F, condition the specimens at the tempertaure and humidity of the manufacturers testing facility for not less than 1 h or until the specimens are at the room temperature.

7.3.3 For referee testing at 32°F, condition the specimens at 32 ± 3.6°F (0 ± 2°C) for at least 2 h, or in ice water for at least 1 h.

7.4 *Test Conditions*:

7.4.1 For referee purposes, conduct tests in the standard laboratory atmosphere of 73.4 ± 3.6 F° (23 ± 2°C) and 50 ± 5 % relative humidity.

7.4.2 For routine quality control testing, conduct tests at the temperature and humditiy of the manufacturers testing area.

7.4.3 For testing at 32°F, complete the test as soon as possible after removal from the conditioning atmosphere, but in any case within 15 s.

7.5 *Test Methods*—Only ASTM test methods specified shall be used.

8. Retest and Rejection

8.1 If the results of any test(s) do not meet the requirements of this specification, the test(s) shall be conducted again only by agreement between the purchaser and the seller. Under such agreement, minimum requirements shalll not be lowered, changed, or modified, nor shall specification limits be changed. If, upon retest, failure occurs, the quantity of product represented by the test(s) does not meet the requirements of this specification.

9. Product Marking

9.1 *Quality of Marking*—The marking shall be applied to the pipe in such a manner that it remains legible (easily read) after installation and inspection.

9.2 *Content of Marking*—The pipe shall be marked in letters not less than 3/16in. (5 mm) high, in a contrasting color, spaced at intervals of not more than 5 ft. (1.5 m), with the following information:

9.2.1 Manufacturer's name (or trademark).

9.2.2 This designation "ASTM F 628".

9.2.3 The wording "COEXTRUDED ABS CELLULAR CORE DWV".

9.2.4 Nominal pipe size (for example: 2 in. (51 mm)).

9.2.5 Manufacturer's code for resin manufacture, lot number, and date of manufacture.

10. Quality Assurance

10.1 When the product is marked with this designation, F 628, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

11. Keywords

11.1 ABS; cellular; DWV; fittings; pipe; plastic; thermoplastic; Schedule 40

SUPPLEMENTARY REQUIREMENTS

GOVERNMENT/MILITARY PROCUREMENT

These requirements apply *only* to federal/military procurement, not domestic sales or transfers.

S1. *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

NOTE S1.1—In U.S. Federal Government contracts, the contractor is responsible for inspection.

S2. *Packaging and Marking for U.S. Government Procurement:*

S2.1 *Packaging*—Unless otherwise specified in the contract, the material shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition and which will be acceptable to the carrier at lowest rates. Containers and packing shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

S2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE S2.1—The inclusion of U.S. Federal Government procurement requirements should not be construed as an indication that the U.S. Federal Government uses or endorses the products described in this specification.

ANNEX

(Mandatory Information)

A1. ABS FITTINGS

A1.1 The pattern, dimension, and laying length of fittings shall meet the requirements of Specification D 3311 and Table A1.1 when determined in accordance with Test Method D 2122.

A1.2 Fittings produced by any molding process shall be made of virgin ABS plastic which shall conform to the requirements prescribed in Specification D 3965 with a cell classification of 3-2-2-2-2. The color and form of the material shall be as agreed upon between the seller and the purchaser in accordance with Specification D 3965.

A1.3 *Rework Material*—The manufacturer shall use only his own clean rework pipe material conforming with these cell class requirements. Use it only in the core layer. The pipe produced shall meet all the requirements of this specification.

A1.4 The spigot dimensions of the fittings shall meet the requirements of Table 1 of this specification.

A1.5 For all fittings having taper pipe threads, threads shall conform to and be gaged in accordance with Specification F 1498.

A1.6 Individual fittings assembled shall withstand a minimum load of 750 lbf/ft (11 kN/m) of centerline length without visible evidence of failure when tested in accordance with Test Method D 2412.

A1.7 Individual fittings assembled shall meet a minimum impact of 20 ft·lbf (27 J) when tested in accordance with Test Method D 2444 at 73°F (23°C) using a 12-lb (5-kg) Tup C and Holder B.

A1.8 Solvent cement meeting the requirements of Specification D 2235 shall be used to join pipe and fittings.

A1.9 Fittings shall be marked on the body or hub with the manufacturer's name or trademark, this designation, "ASTM F 628", and the symbol "ABS".

1½	1.910 (48.51)	+0.010 (0.25) −0.005 (0.13)	0.024 (0.61)	1.895 (48.13)	±0.005 (0.13)	0.024 (0.61)	0.687 (17.45)	0.156 (3.96)	0.140 (3.56)	2.127 (54.03)	0.687 (17.4)
2	2.385 (60.58)	+0.010 (0.25) −0.005 (0.13)	0.024 (0.61)	2.370 (60.19)	±0.005 (0.13)	0.024 (0.61)	0.750 (19.05)	0.156 (3.96)	0.140 (3.56)	2.634 (66.90)	0.750 (19.0)
3	3.515 (89.28)	+0.010 (0.25) −0.005 (0.13)	0.030 (0.76)	3.495 (88.73)	+0.005 (0.13) −0.010 (0.25)	0.030 (0.76)	1.500 (38.1)	0.218 (5.54)	0.196 (4.98)	3.841 (97.56)	1.187 (30.15)
4	4.515 (114.68)	+0.010 (0.25) −0.005 (0.13)	0.030 (0.76)	4.495 (114.17)	+0.005 (0.13) −0.010 (0.25)	0.030 (0.76)	1.750 (44.45)	0.250 (6.35)	0.225 (5.72)	4.907 (124.64)	1.281 (32.54)
6	6.647 (168.83)	±0.011 (0.28)	0.060 (1.52)	6.614 (167.99)	±0.011 (0.28)	0.060 (1.52)	3.000 (76.20)	0.281 (7.14)	0.253 (6.43)	7.203 (182.96)	1.500 (38.10)

[A] The average wall thickness is the minimum wall thickness plus the opposite wall thickness divided by 2. The average shall equal or exceed that shown in the table. The minimum wall thickness, due to core shift, shall equal or exceed the value shown in the table. The minimum wall thickness is determined by allowing a 10 % variation due to core shift.

[B] The average is the maximum plus the minimum diameters divided by 2.

APPENDIXES

(Nonmandatory Information)

X1. STORAGE

X1.1 *Outside Storage*—Plastic pipe should be stored on a flat surface or supported in a manner that will prevent sagging or bending. Do not store pipe in direct sunlight forlong periods.

X1.2 Inventories of plastic pipe should be used on a first-in-first-out basis.

X2. JOINING

X2.1 *Field Inspection*—Prior to use, all pipe should be carefully inspected for cuts, gouges, deep scratches, damaged ends, and other major imperfections. Defective pipe should be rejected and damaged sections should be cut out.

X2.2 *Pipe Fit*—Pipe is manufactured to close tolerances to ensure satisfactory "interference" fit between the pipe and the fittings socket during assembly. Use only combinations of pipe and fittings that give interference fits. Pipe that is a loose fit in the socket may not properly bond. The allowable tolerance assures a forced fit and when solvent cement is applied, the pipe and fitting will readily mate, thus assuring proper adhesion. The pipe should enter the dry fitting socket to between one half and two thirds of the fitting socket depth.

X2.3 *Cutting*—Pipe can be easily cut with an ordinary hacksaw or carpenter's saw. Fine-tooth blades with little or no set should be used for best results. The pipe should be cut square and all burrs removed with a sharp knife, a fine-tooth file, or other suitable tool such as chamfering tool or reamer. A miter box is recommended to ensure square cut ends. Standard steel pipe or tubing cutters are not recommended for cutting ABS pipe since they may cause excessive heat and pressure, which can result in cracked or irregular pipe ends. There are special plastic pipe cutters available with extra wide rollers and thin cutting wheels that have been especially designed for cutting plastic pipe, and their use is recommended.

X2.4 *Cleaning*—Remove burrs from inside and outside pipe edges. Wipe off all dust, dirt, and moisture from surfaces to be cemented with a clean dry rag or a paper towel. At no time should pipe or fittings be assembled that are wet or damp. Pipe and fittings must be dry before assembly to obtain good joints.

X2.5 *Safety Requirements for Solvent Cement and Primers*—Follow Practice F 402.

X2.6 *Solvent Cement*—Use only solvent cement designed for ABS. Use a solvent cement meeting the requirements of Specification D 2235.

X2.6.1 *Application of Cement*—Using the applicator supplied with the can of solvent cement, or a brush or roller with a width of about one half the pipe diameter for pipe sizes above 2 in. (51 mm), apply a moderate even coating of cement in the fitting socket to cover only the surfaces to be joined. Heavy or excessive application of solvent cement may become an obstruction in the pipe and prevent satisfactory joining. Quickly apply a heavy coat of solvent cement to the outside of the pipe. Make sure that the coated distance on the pipe is equal to the depth of the fitting socket.

X2.7 *Assembly*—Make the joint as quickly as possible after application of the solvent cement and before the solvent cement dries. Should the solvent cement dry partially before the joint is made up, reapply solvent cement before assembling. Insert the pipe into the fitting socket, making sure that the pipe is inserted to the full depth of the fitting socket. Hold joint together firmly for about 30 s for small diameter pipe and 60 s for diameters above 6 in. (152 mm) to avoid push-out. Remove excessive solvent cement from the exterior of the joint with a clean, dry cloth.

X2.8 *Set Time*—Do not attempt to disturb the pipe and fitting joint until after the solvent cement has set or damage to the joint and loss of fit may result. Reasonable handling of assembly is permissible within 2 min after joining. Allow 15 min for the joint to develop good handling strength and the joint will withstand the stresses of normal installation. A badly misaligned installation will cause excessive stresses in the joint, pipe, and fittings and constitutes a plumbing code violation and should be avoided. The recommendation of the solvent cement manufacturer should be followed for best results.

X2.9 *Cure Time*—Joint strength development is very rapid during periods of high ambient temperatures, low relative humidity, and using interference-type fittings. Joint strength development is not as rapid during periods of low ambient temperatures, high relative humidity, and using loose fits. Therefore, the recommendations of the solvent cement manufacturer should be followed for best results prior to leak testing.

Wed Feb 02 02:07:27 2005

X3. INSTALLATION

X3.1 *Underground Installation*—Underground installations of pipe shall be in accordance with the excavation, bedding and backfill provisions of the Plumbing Code having jurisdiction, except maximum aggregate size shall be limited to ½ in. (13 mm) for angular and ¾ in. (19 mm) for rounded particles. For special conditions consult Practice D 2321.

X3.2 *DWV Installation*—Pipe should be installed in conformance with governing building codes. In areas not governed by codes, pipe should be installed in accordance with accepted engineering practices.

X3.3 *Installation Under Freezing Conditions*—Plastic pipe has decreased resistance to impact under freezing conditions. Increased care should be exercised if installation is likely to occur under these conditions, particularly during handling, transportation, installation, and backfilling. Where possible, installation should be avoided during freezing conditions. Allowance shall be made for expansion that will occur when the temperature of the pipe is raised.

X3.4 *Alignment and Grade*—Align all piping system components properly without strain. Do not bend or pull pipe into position after being solvent cemented. The grade of horizontal drainage and vent piping shall be as specified in the applicable code.

X3.5 *Supports and Spacing*—Hangers and straps should not compress, distort, cut, or abrade the piping and should allow free movement of pipe. Support all piping at intervals of not more than 4 ft (1.2 m) at end of branches and at changes of direction or elevation. Supports should allow free movement. Maintain vertical piping in straight alignment with supports at each floor level or at 10-ft (3.1-m) intervals, whichever is less. Support trap arms in excess of 3 ft (0.9 m) in length as close as possible to the trap. Securely fasten closed flanges with corrosion-resistant fasteners to the floor with the top surface ¼ in. (6.4 mm) above the finish floor level. Stabilize closet bends or stubs against all horizontal or vertical movement. Protect pipe exposed to damage by sharp surfaces with gromets or sleeves of rubber or plastic.

X3.6 *Threaded Connections*—Do not cut threads on pipe. Molded threads on adapter fittings for transition to threaded construction is necessary except in the case of cleanout plugs. The joint between the pipe and transition fittings should be of the solvent cement type. Only approved thread tape or thread lubricant specifically intended for use with ABS plastic pipe should be used. Conventional pipe thread compound, putty, linseed oil base products, and unknown mixtures should be avoided.

X3.7 *Thread Tightness*—Where a threaded joint is made, obtain tightness by a maximum hand tightening plus additional tightening with a strap wrench, not to exceed one full turn.

X3.8 *Connection to Nonplastic Pipe*—When connecting plastic pipe to other types of piping, use only approved types of fittings and adapters designed for the specific transition.

X3.9 *Connections to Traps*—Connect traps by means of approved threaded trap adapters.

X3.10 *Connection to Closet Flanges*—Install screw-type closet flanges in the drainage system by means of a threaded connection.

X3.11 *Transition to Bell-and-Spigot Pipe*—Make connections or transition to bell-and-spigot cast iron soil pipe and fittings, and to bell-and-spigot pipe and fittings of other materials with approved mechanical compression joints designed for this use, or caulk joints made in an approved manner.

X3.12 *Building Drains Under Floor Slabs*—Make trench bottoms smooth and of uniform grade with either undisturbed soil or a layer of selected and compacted-backfill so that no settlement will be encountered. Bottom of pipe must rest on this material throughout the entire length.

X3.13 *Thermal Expansion*—Allow for thermal expansion and movement in all piping installations by the use of approved methods. Support but do not rigidly restrain piping at branches or changes of direction. Do not anchor pipe rigidly in walls. Holes through framing members should be adequately sized to allow for free movement. Thermal expansion for installations subject to temperature changes may be determined from Table X3.1. The linear expansion shown is independent of the diameter of the pipe. Buried piping or piping installed in the crawl space under a building is normally subject to less than the ambient temperature changes.

X3.14 *Exposed Piping*—Provide adequate support where

TABLE X3.1 Thermal Expansion Table of ABS Schedule 40 Drain, Waste, and Vent Pipe Produced by the Coextrusion Process with Concentric Inner and Outer Solid ABS Layers and the Core Consisting of Closed-Cell Cellular ABS

Length, ft	Temperature Change, °F[A]						
	40	50	60	70	80	90	100
	Length of Change, in.[B]						
20	0.5	0.7	0.8	0.9	1.0	1.2	1.3
40	1.1	1.3	1.6	1.9	2.0	2.4	2.7
60	1.6	2.0	2.4	2.8	3.2	3.6	4.0
80	2.1	2.7	3.2	3.8	4.3	4.8	5.4

Length, m	Temperature Change, °C			
	20	30	40	50
	Length of Change, mm			
10	20	30	40	50
20	40	60	80	100
30	60	90	120	150

[A] Example of Temperature Change:

Highest Temperature Expected	100°F
Lowest Temperature Expected	50°F
Total variation	50°F

[B] For a length of run of 60 ft (20 m) the chart indicates that the installation should provide for a linear expansion of 2 in. (51 mm).

Copyright by the ASTM International
Wed Feb 02 02:07:27 2005

piping is exposed to wind, snow, and ice loading. Plumbing vents exposed to sunlight should be protected by water-base synthetic latex paints. Where surface temperatures exceed 165°F (74°C), piping shall be protected by means of shielding or some type of lightweight insulation. Exposure to sunlight during normal construction periods is not harmful. It is good practice to store pipe and fittings under suitable cover prior to installation.

X3.15 *Antifreeze Protection*—When necessary to protect traps and fixtures from freezing, do not use alcohol or petroleum products. Use only approved plastic pipe antifreeze packaged for this purpose or one of the following solutions:

X3.15.1 Sixty percent, by mass, of glycerin in water.

X3.15.2 Twenty-two percent, by mass, of magnesium chloride in water. Strong solutions of common table salt (sodium chloride) may also be used.

X3.16 *Commercial and Industrial Applications:*

X3.16.1 The DWV pipe will accommodate temperature of 180°F (82°C) encountered in household applications, but the nature of some applications is to run to higher temperatures; for example, commercial dishwashers, require special consideration.

X3.16.2 Waste disposal lines where concentrated agents and certain chemicals that are routinely present and that may be aggressive to ABS should only be installed with the specific approval of the cognizant building code authority. Service station bay area floor drains require special consideration.

X3.17 *Fire-Rated Construction*—When the piping is to be installed within or penetrating fire-rated constructions, the cognizant building code authorities should be consulted for approved methods of construction of fire barriers.

NOTE X3.1—Fire barriers are either mechanical devices that close off penetration openings or intumescent materials that expand with heat to form a char that make a flame and water-resistant seal.

X3.17.1 All fire barriers should bear the seal of approval and classification of the approving laboratory recognized as qualified to perform such evaluations, for example, UL.

NOTE X3.2—Use fire barrier products meeting this requirement.[7]

[7] Fire barrier products that have been found satisfactory for this purpose are: "Flamarest," available from Avco Systems Division, Lowell Industrial Park, Lowell, MA 01851; "Flameseal," available from Nelson Electric, P.O. Box 726, Tulsa, OK 74101; "Firebarrier," available from 3M, Electrical Products Division, 225-4N 3M Center, St. Paul, MN 55144 and "Fire Stop Foam," available from Dow Corning, Dept. A 6009, Midland, MI 48686.

X4. PREFABRICATED PLUMBING TREES

X4.1 When prefabricated plumbing trees are assembled, it is important that the recommendation of Appendix X2 on joining and Appendix X3 on installation, where applicable, be followed for satisfactory results.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Standard Specification for Perfluoro (Alkoxyalkane) Copolymer (PFA) Plastic-Lined Ferrous Metal Pipe and Fittings[1]

This standard is issued under the fixed designation F 781; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers factory-made perfluoro (alkoxyalkane) copolymer (PFA) plastic-lined ferrous metal pipe and fittings, primarily intended for conveying corrosive liquids and gases. Requirements for materials, workmanship, dimensions, design, construction, working pressures and temperatures, test methods, and markings are included.

1.2 The values given in parentheses are provided for information purposes only.

NOTE 1—This specification does not include products coated with PFA nor does it define the suitability of PFA-lined components in chemical environments.

1.3 The ferrous piping products shall meet the requirements of the relevant specification listed in 1.3.1 through 1.3.4. Nominal sizes from 1 through 12 in. in 150 and 300 psi (1.0 to 2.0 MPa) ratings are covered.

NOTE 2—The PFA sealing faces may prevent achievement of the full pressure rating of the ferrous housings. For pressure limitations, the manufacturer should be consulted.

1.3.1 *For Ferrous Pipe:*[2,3]

Title of Specification	ASTM Designation
Pipe, Steel, Black, and Hot-Dipped, Zinc-Coated Welded and Seamless	A 53
Seamless Carbon Steel Pipe and High-Temperature Service	A 106
Electric-Resistance-Welded Steel Pipe	A 135
Electric-Welded Low-Carbon Steel Pipe for the Chemical Industry	A 587
Seamless and Welded Austenitic Stainless Steel Pipe	A 312

1.3.2 *For Ferrous Flanges:*[2,3]

Title of Specification	ASTM Designation
Forgings, Carbon Steel, for Piping Components	A 105
Forged or Rolled Steel Pipe Flanges, Forged Fittings and Valves and Parts for General Service	A 181
Forged or Rolled Alloy-Steel Pipe Flanges, Forged Fittings, and Valves and Parts for High-Temperature Service	A 182
Carbon-Steel Castings Suitable for Fusion Welding for High-Temperature Service	A 216
Ferritic Ductile Iron for Pressure Retaining Castings for Use at Elevated Temperatures	A 395
Ductile Iron Castings	A 536

1.3.3 *For Ferrous Fittings:*[2,3]

Title of Specification	ASTM Designation
Forgings, Carbon Steel, for Piping Components	A 105
Forged or Rolled Steel Pipe Flanges, Forged Fittings, and Valves and Parts for General Service	A 181
Carbon Steel Castings Suitable for Fusion Welding for High-Temperature Service	A 216
Piping Fittings Wrought Carbon Steel and Alloy Steel for Moderate and Elevated Temperatures	A 234
Austenitic Steel Castings for High-Temperature Service	A 351
Alloy Steel Castings Specially Heat-Treated for Pressure Containing Parts Suitable for High-Temperature Service	A 389
Ferritic Ductile Iron for Pressure Retaining Castings for Use at Elevated Temperatures	A 395
Ductile Iron Castings	A 536
Ductile Iron for Pressure Containing Castings for Use at Elevated Temperatures	A 403

1.4 The PFA-lined flanged pipe and fitting assemblies are limited to use from −20 to 500°F (−29 to 260°C). For use below −29°C (−20°F) consult the manufacturer.

NOTE 3—The above temperature limitations are based on noncorrosive test conditions. Use in specific aggressive environments may alter the above temperatures, and these limits shall be established by mutual agreement between the purchaser and manufacturer.

TABLE 1 Face Diameter

Nominal Pipe Size, in.	Minimum PFA Face Diameter, in. (mm)
1	1⅞ (48)
1.5	2¹¹⁄₁₆ (68)
2	3⁷⁄₁₆ (87)
3	4⅝ (117)
4	5¹⁵⁄₁₆ (151)
6	8 (203)
8	10¹⁄₁₆ (256)
10	12¼ (311)
12	14⅜ (365)

4. Materials

4.1 *Lining:*

4.1.1 *Material*—The lining shall be made from PFA resins conforming to the requirements of Type II materials as defined in Specification D 3307 except that a maximum of 1 % by weight of additives or colorants, or both, is permissible. Organic colorants, if used, shall be identified in the manufacturer's specification.

4.1.2 *Mechanical Properties*—The minimum tensile strength and minimum elongation at yield when tested in accordance with the requirements of Specification D 3307 shall be 3800 psi (26 MPa) and 300 % respectively.

4.1.3 *Flow Rate*—PFA resins used to manufacture the liner and molded fittings shall have a maximum flow rate of 3.0 g/10 min when tested in accordance with Specification D 3307.

4.2 *Ferrous Pipe and Fittings:*

4.2.1 The mechanical properties of the pipes and fittings shall conform to the requirements of the appropriate specification of 1.3 except as they are influenced by accepted methods of processing in the industry, for example, Van Stone flaring, bending, swagging, and welding. The carbon steel pipe and wrought fittings shall be welded or seamless steel. Schedule 40 or Schedule 80, except that Schedule 30 pipe may be used in 8, 10, and 12-in. nominal size. Schedule 20 may also be used for 12-in. nominal size with the agreement of the purchaser.

4.2.2 *Finish*—The interior surfaces of all housings shall be clean and free of mold burrs, rust, scale, or other protrusions, that may adversely affect the integrity or performance of the lining.

4.3 *Back-Up Gaskets:*

4.3.1 *General*—Back-up gaskets shall be used to cover the pipe and gasket face of threaded or slip-on flanges unless a full radius is provided at the end of the pipe and flange. Gaskets may also be required on fittings to provide accommodation, or elimination, or both, of sharp corners that could damage the lining.

4.3.2 *Material*—Plain gaskets meeting the temperature requirements, or perforated metallic gaskets, may be used.

TABLE 2 Tolerances for Pipe, Flanges, and Fittings

Pipe	Tolerance, in. (mm)
Length	±⅛ (±3.2)
Fixed flange bolt hole alignment	±¹⁄₁₆ (±1.6)
Flange perpendicularity (with pipe centerline)	³⁄₃₂ in./ft. of diameter (7.8 mm/m of diameter
Flanges and Fittings	
All dimensions	per ANSI B16.5

5. Requirements

5.1 *Dimensions:*

5.1.1 *Housings*—Housing installation dimensions are as required in the applicable material specification listed in 1.3.

5.1.2 *Wall Thickness*—Fitting linings shall have a minimum wall thickness of ³⁄₃₂ in. (2.38 mm), and shall have a uniform face thickness of not less than ³⁄₃₂ in. (2.38 mm). Pipe linings shall have a minimum wall thickness of 0.050 in. (1.27 mm), and the flared radius and gasket faces shall have a uniform thickness not less than 80 % of the wall thickness.

5.1.3 *PFA Face Diameter*—The outside diameter of the PFA covering the gasket face of the flange or the full face of the lap-joint stub end shall not be less than the diameter specified in Table 1 and they shall be concentric within ¹⁄₁₆ in. (1.6 mm).

5.1.4 *Tolerances*—Tolerances for pipe, flanges, and fittings shall be as specified in Table 2. Bolt holes in both flanges on a fixed-flange spool shall straddle the same center line to facilitate alignment. Finished lined (plastic face to plastic face) fabricated fittings shall conform to the nominal face-to-face, etc. as specified in ANSI B16.5 with the applicable tolerances.

5.2 *Flange Construction:*

5.2.1 Screw-type flanges shall be secured in position to prevent inadvertent turning of the flange.

5.2.2 Socket-type flanges shall be fully back-welded to the pipe housing and the inside surfaces of the socket flanges shall be welded and ground smooth.

5.2.3 Slip-on flanges shall be fully backwelded.

NOTE 4—No welding shall be done on lined components.

5.2.4 Lap-joint (or Van Stone) flanged ends may be manufactured by standard forming techniques or by using fully welded stub ends or collars. Lap-joints shall not contain any cracks or buckles.

NOTE 5—The use of lap-joint flanges in a piping system may simplify alignment.

5.3 *Venting*—Each pipe and fittings shall be provided with a venting system that will release any gases between the linear and the housing (this system will also indiate any leakage through the liner). Two systems that provide adequate venting are a series of ¹⁄₁₆ to ⁵⁄₃₂-in. (1.6 to 4-mm) diameter holes in the housings or a helical groove system inside the housing that connects flange vents.

NOTE 6—Vent holes should not be plugged with paint, cement, etc., since this negates the intended purpose listed in 5.3.

5.4 *Workmanship:*

5.4.1 Pipe and fitting linings shall show no evidence of pinholes, porosity, or cracks when inspected in accordance with 5.5.2. The linings shall fit snugly inside the pipe and fitting housings. Any bulges or other obvious indication of poor contact with the housing shall be cause for rejection.

5.4.2 The gasket face of the PFA-linings shall be free of surface defects that could impair sealing effectiveness. Scratches, dents, nicks, or tool marks on the gasket surface shall not be deeper than 10 % of the wall thickness.

5.5 *Performance:*

5.5.1 *Qualification*—PFA-lined pipe and fittings must be capable of meeting the requirements specified in Section 6.

5.5.2 *Inspection:*

Copyright by the ASTM International
Wed Feb 02 02:07:58 2005

5.5.2.1 Each lined pipe and fitting, prior to shipment, shall be subjected to a hydrostatic test or an electrostatic test, or both, as specified in 7.1 or 7.2. The test or tests to be used shall be at the option of the manufacturer, unless otherwise specified by the purchaser.

5.5.2.2 Each lined pipe and fitting shall subsequently be visually inspected prior to shipment to verify conformance to the design and dimensional requirements of 5.4.

5.5.2.3 Each lined pipe and fitting shall bear an inspection verification impression stamp on the housing to indicate compliance with the requirements of this specification.

6. Qualification Tests

6.1 *Temperature Tests:*

6.1.1 Cycle representative production samples of PFA-lined pipe and fittings in an oven from room temperature to 500 ± 5°F (260 ± 3°C) to determine the ability of the lined components to withstand heat aging and temperature cycling. Test a minimum of two pipe spools, tees, and 90° elbows in each size.

6.1.2 Install companion flanges at the manufacturer's recommended torque value, and affix a thermocouple to the ferrous housing to measure the temperature. Pipe spools shall be at least 3 ft (0.9 m) long. After 3 h in an oven at 500°F (265°C) as indicated by the thermocouple, air-cool the lined components to 122°F (50°C) maximum. Repeat this test for a total of three cycles.

6.1.3 Inspect PFA-lined pipe and fittings after each cycle for distortion or cracks in the PFA lining. At the completion of the third cycle, subject-specimens to either the hydrostatic or electrostatic test described in 7.1 or 7.2.

6.2 *Steam-Cold Water Cycling Test:*

6.2.1 Subject representative production samples of PFA-lined pipe and fittings to steam-cold water cycling to determine the ability of the lined components to withstand rapid temperature changes. Test a minimum of two pipe spools, tees, and 90° elbows in each size.

6.2.2 Assemble PFA-lined pipe and fittings with suitable blind flanges having provision for the introduction of steam, air, or cold water and for drainage. Install the flanges using the manufacturer's recommended torque value. Pipe spool length shall be 10 ft (3.05 m) minimum. Mount the test specimens in such a manner as to permit complete drainage and then subject them to 100 steam-cold water cycles, each of which shall consist of the following in the sequence given:

6.2.2.1 Circulate saturated steam at a gage pressure of 125 ± 5 psi (862 ± 35 kPa) through the specimens until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen has been maintained at the maximum stabilized temperature for 30 min.

6.2.2.2 Close off steam. Vent and introduce air to purge the specimens for a minimum of 1 min.

6.2.2.3 Circulate water at a maximum temperature of 77°F (25°C) until the ferrous housing skin temperature adjacent to the flange at the outlet end of the test specimen measures 122°F (50°C) maximum.

6.2.2.4 Drain, then introduce air to purge the specimens for a minimum of 1 min, making certain that specimens are completely drained.

6.2.3 There shall be no evidence of leakage from the venting system or the flanges during the 100 cycles. At the completion of the test, the linear shall show no evidence of buckling, cracking, or crazing. Formation of water blisters shall not be cause for rejection.

NOTE 7—These surface blisters extend only partially into the wall thickness and are formed due to absorption of steam by the PFA liner and subsequent condensation in the liner. The blisters do not adversely affect PFA liner performance.

6.2.4 At the conclusion of the testing specified in 6.2.2, subject the PFA-lined pipe or fitting to the hydrostatic test specified in 7.1 or, after drying, to the electrostatic test specified in 6.2.

6.3 *Vacuum Testing:*

6.3.1 Test representative production samples of PFA-lined pipe and fittings to determine the vacuum ratings of the lined components. Test a minimum of two pipe spools, tees, and 90° elbows in each size. Conduct tests at room temperature and at the manufacturer's maximum recommended service temperature, and at one intermediate temperature if a full vacuum rating cannot be achieved at the maximum recommended service temperature. Full vacuum is defined as 29.6 in. Hg (100 kPa) corrected.

NOTE 8—Vacuum-temperature ratings are published in the manufacturer's literature.

6.3.2 For pipe spools, specimen length shall be at least ten pipe diameters. Install a flange incorporating a sight glass at one end and a blind flange suitable for drawing a vacuum at the other end. Provide for measuring the ferrous housing temperature.

6.3.3 Heat the specimens uniformly and externally with the sight glass end visible, and after the desired ferrous housing temperature is reached, begin the test. Hold a selected initial vacuum level for 24 h and if no failure occurs, increase the vacuum by 2 in. Hg (6.8 kPa). Repeat this every 4–6 h until failure or full vacuum is reached. Failure is defined as any buckling or collapse of the liner.

6.3.4 If failure occurs at the initial vacuum level selected, test a new test specimen at a lower vacuum level to determine the failure threshold. The vacuum failure threshold is defined as 1 in. Hg (3.4 kPa) below that at which failure occurs.

NOTE 9—The external pressure method to simulate higher than full vacuum can be used to establish the failure threshold when full vacuum is achievable. With the use of pressure taps, an external pressure is applied between the liner outside and the pipe inside diameter.

6.3.5 The vacuum rating shall be 80 % of the failure threshold value.

6.3.6 At the test completion and after the vacuum rating is established, heat a duplicate specimen to the test temperature. Apply the rated vacuum to the specimen after the desired skin temperature has been reached. Achieve the rated vacuum within 2 min and apply continuously for 48 h. If no liner buckling or collapse occurs, the vacuum rating shall be considered acceptable.

6.4 *Retest*—When a test specimen fails to meet the requirements of 6.1, 6.2, or 6.3, the cause of failure shall be sought and corrected. Then repeat the temperature test specified in 6.1 and the steam-cold water cycling test specified in 6.2 and vacuum test specified in 6.3, using double the number of test specimens.

7. Inspection Tests

7.1 *Hydrostatic Pressure Test*—The internal test pressure shall be 425 psi (2.93 MPa) minimum. Conduct the test at ambient temperature. Fill the pipe and fitting completely with clean water and bleed the system free of all air pior to the application of pressure. Reach full test pressure within 1 min and maintain for a further 3 min. Observe the pressure gage and the venting system in the test specimen throughout the test for any evidence of leakage, which shall be cause for rejection.

7.2 *Electrostatic Test*—Conduct the test with a non-destructive high-voltage tester at an output voltage of 10 000 V. A visible or audible spark, or both, that occurs at the probe when electrical contact is made with the housing because of a defect in the liner, shall be cause for rejection.

8. Finish

8.1 The outside surface all lined pipe and fittings, other than stainless steel, shall be coated with a corrosion-resistant primer over a properly prepared surface.

9. Marking

9.1 The markings shall be applied to the pipe in such a manner that they remain legible (easily read) after installation and inspection.

9.2 Marking on the pipe and fitting shall include the following:

9.2.1 Nominal pipe size,

9.2.2 Liner material identification (PFA),

9.2.3 Manufacturer's name (or trademark),

9.2.4 This designation "ASTM F 781", and

9.2.5 Length (on pipe only).

9.2.6 Other information such, as order numbers, part numbers, item numbers, etc., shall be provided at the purchaser's request.

9.3 Pipe liner indentification shall be provided on a band containing the raised letters "PFA".

10. Packaging

10.1 The gasket face of each lined pipe and each fitting shall be protected by end plates or other suitable protective means, such as, individual boxing.

11. Federal Procurement

11.1 *Responsibility for Inspection*—Unless otherwise specified in the contract or purchase order, the producer is responsible for the performance of all inspection and test requirements specified herein. The producer may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

NOTE 10—In Federal contracts, the contractor is responsible for inspection.

11.2 *Packaging and Marking for U.S. Government Procurement:*

11.2.1 *Packaging*—Unless otherwise specified in the contract, the material shall be packaged in accordance with the supplier's standard practice in a manner ensuring arrival at destination in satisfactory condition, and which will be acceptable to the carrier at lowest rates. Containers and packaging shall comply with Uniform Freight Classification rules or National Motor Freight Classification rules.

11.2.2 *Marking*—Marking for shipment shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

NOTE 11—The inclusion of U.S. Government procurement requirements shall not be construed as an indication that the U.S. Government uses or endorses the products described in this document.

12. Quality Assurance

12.1 When the product is marked with this designation, F 781, the manufacturer affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 100 Barr Harbor Drive, West Conshohocken, PA 19428.

Standard Specification for Thermosetting Resin Fiberglass Pipe and Fittings to be Used for Marine Applications[1]

This standard is issued under the fixed designation F 1173; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 This specification covers machine made reinforced thermosetting epoxy resin pipe and fittings nominal pipe size (NPS) 1 through 48 in. in diameter to be used in marine piping systems in which resistance to corrosion, aging, and deterioration from seawater, gas, chemicals, and sea environment is required.

1.2 When invoked by military or other procurement activities, MIL-P-24608 (SH) shall apply.

1.3 The values stated in inch-pound units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The dimensionless designator NPS has been substituted in this standard for such traditional terms as "nominal diameter," "size," and "nominal size."

1.5 The specific maximum temperature and pressure covered by this specification is 240°F (115.6°C) and 225 psi (15.5 bar).

1.6 The following safety hazards caveat pertains to the test methods portion, Section 11, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

National Sanitation Foundation Standard 14[9]
MIL-P-24608 (SH) Pipe, Fittings, and Adhesive Kits, Glass Reinforced Thermosetting Epoxy Resin for Shipboard Piping Systems[10]
IMO Assembly Resolution A.753(18)[10]

3. Terminology

3.1 *Definitions*—Definitions are in accordance with Terminologies D 883 or F 412, and abbreviations are in accordance with Terminology D 1600, unless otherwise indicated.

3.2 *Descriptions of Terms Specific to This Standard:*

3.2.1 *maximum operating pressure*—the highest pressure that can exist in a system or subsystem under normal operating conditions. This pressure is determined by such influences as pump or compressor shut-off pressures, pressure regulating valve lockup (no flow) pressure, and maximum chosen pressure at the system source.

3.2.2 *representative piping system*—a system composed of a single manufacturer's pipes, fittings, joints, and adhesives that would normally be used by a customer or installer. If the system is conductive, any devices normally supplied by the manufacturer (either as electromechanical attachments or integrated into the composite structure) for electrical continuity or grounding are to be included as well.

4. Classification

4.1 *General:*

4.1.1 Pipe meeting this specification is classified by type, grade, and class similar to Classification D 2310.

4.1.2 Fittings meeting this specification are also classified by types (method of manufacture), grades (generic type of resin), and classes (joining system).

4.1.3 Joints meeting this specification are classified only as being conductive or non-conductive.

4.2 *Types:*

4.2.1 *Type I*—Filament-wound (pipe and fittings).

4.2.2 *Type II*—Centrifugally cast (pipe and fittings).

4.2.3 *Type III*—Molded (fittings only).

4.3 *Grades:*

4.3.1 *Grade I*—Epoxy/Epoxy Vinyl Ester resin (pipe and fittings).

4.3.2 *Grade II*—Polyester Resins (pipe and fittings).

4.3.3 *Grade III*—Customer Specified Thermosetting resin (pipe and fittings).

4.4 *Classes:*

4.4.1 *Pipe and Fittings Only:*

4.4.1.1 *Class A*—No liner.

4.4.1.2 *Class B*—Liner, reinforced.

4.4.1.3 *Class C*—Conductive, no liner.

4.4.1.4 *Class D*—Reinforced with conductive outer layer.

4.4.2 *Joining System:*

4.4.2.1 *Class E*—Non-conductive joint.

4.4.2.2 *Class F*—Conductive joint.

4.5 *Piping Systems*, including pipes, joints, and fittings, along with any applicable fire protection coatings or coverings shall meet at least one of the following three levels of full scale fire endurance.

4.5.1 *Level 1*—Piping systems must satisfy the acceptance criteria defined in Annex A4 and pass the fire endurance test method specified in Annex A4 for a duration of a minimum of one h.

4.5.2 *Level 2*—Piping systems must satisfy the acceptance criteria defined in Annex A4 and pass the fire endurance test method specified in Annex A4 for a duration of a minimum of 30 min.

4.5.3 *Level 3*—Piping systems must satisfy the acceptance criteria defined in Annex A5 and pass the fire endurance test method specified in Annex A5 for a duration of a minimum of 30 min.

4.5.4 Piping and insulation systems should not drip during full scale evaluations for levels 1, 2, or 3.

5. Ordering Information

5.1 When ordering pipe and fittings under this specification, the following should be specified:

5.1.1 Designation and date of this specification.

5.1.2 Type.

5.1.3 Grade.

5.1.4 Class.

5.1.5 NPS.

5.1.6 Manufacturer's identification (for example, part number, product's name, etc.).

5.1.7 Specific customer requirements, if any.

6. Materials and Manufacture

6.1 *Materials:*

6.1.1 *General*—The resins, reinforcements, colorants, fillers, and other materials, when combined as a composite structure, shall produce a pipe that shall meet the performance requirements of this specification.

6.1.2 *Joining Systems*—The joining system used shall be rated for the same design conditions as the pipe and fittings. This includes design for internal pressure, tensile strength, bending strength, electrical resistance, etc., as called for in Section 7.

6.2 *Manufacture:*

6.2.1 Pipe manufactured by the filament winding process shall be in accordance with Specification D 2996.

6.2.2 Pipe manufactured by the centrifugal casting process shall be in accordance with Specification D 2997.

6.2.3 Fittings shall be manufactured by the filament wound, molded, or centrifugally cast process, using thermosetting resin and glass reinforcement.

7. Performance Requirements

7.1 *General:*

7.1.1 The requirements of this section apply to all piping and piping systems independent of service or location.

7.1.2 The specification of the piping shall meet the performance guidelines that follow.

7.1.3 The structural wall of the piping system shall have sufficient strength to take account of the most severe coincident conditions of pressure, temperature, the weight of the piping itself, and any static and dynamic loads imposed by the design or environment. Once the structural wall

Wed Feb 02 02:08:29 2005

thickness is calculated, the corrosion liner is added to obtain the pipe's total wall thickness.

7.1.4 For the purpose of assuring adequate robustness for all piping systems, including open-ended piping, all pipe, fittings, and joints shall have a minimum structural wall thickness able to withstand loads due to transportation, handling, installation, personnel traffic, etc. This may require the pipe, fittings, and joints to have additional structural thickness than otherwise required by service considerations.

7.1.5 The performance requirements for any component of a piping system such as fittings and joints are the same as those requirements for the piping system they are installed in.

7.2 *Hydrostatic Strength:*

7.2.1 A piping system shall be designed for a maximum operating pressure not less than the maximum working pressure to be expected under operating conditions nor less than the highest set pressure of any safety valve or pressure relief device on the system, if fitted.

7.2.2 The maximum operating pressure for a pipe system shall be determined by dividing the short-term hydrostatic test failure pressure by a minimum safety factor of 4 or the long-term hydrostatic (>100,000 hours) test failure pressure by a minimum safety factor of 2.5, whichever is the lesser of the two. Special design cases, such as where pressure surges can not be accurately estimated or where dynamic loads cannot be accurately accounted for, may warrant safety factors in excess of these values, in some cases as great as 10:1. Either the short-term or the long-term hydrostatic test pressures, whichever is used, shall be verified experimentally or by a combination of testing and calculations to the satisfaction of the approving authority. In all designs, the maximum allowable internal pressure shall be based on the weakest part of the system, be it the pipe, fittings, and flanges or the joining method used.

7.2.2.1 The maximum operating pressure shall be based on the structural wall thickness, not the total wall thickness.

7.3 *External Pressure:*

7.3.1 External pressure shall be taken into account in the design of the piping system for any installation which may be subject to vacuum conditions inside the pipe or a pressure head acting on the outside of the pipe.

7.3.2 A piping system shall be designed for a maximum allowable external pressure not less than the sum of the maximum potential pressure head outside the pipe plus the design vacuum pressure. The maximum allowable external pressure for a piping system shall be determined by dividing the collapse test pressure by a minimum safety factor of 3. Special design cases, such as where pressure surges cannot be accurately estimated or where dynamic loads cannot be accurately accounted for, may warrant safety factors in excess of these values, in some cases as great as 10:1. The collapse test pressure shall be verified experimentally or by a combination of testing and calculation methods to the satisfaction of the approving authority.

7.3.2.1 The maximum allowable external pressure shall be based on the structural wall thickness, not the total wall thickness.

7.4 *Longitudinal Tensile Properties:*

7.4.1 The sum of the longitudinal stresses due to pressure, weight and other dynamic and sustained loads shall not exceed the maximum allowable stress in the longitudinal direction. Forces due to thermal expansion, contraction, and external loads, such as wind loads, seismic loads, etc., shall be considered when determining longitudinal stresses in the system. Internal shock, or pressure surge, commonly known as water hammer, shall also be considered when determining the stresses in the system.

7.4.2 The sum of the longitudinal stresses shall not exceed half of the nominal circumferential stress derived from the nominal internal pressure determined according to 2.2, unless the maximum allowable longitudinal stress is verified experimentally or by a combination of testing and calculation methods to the satisfaction of the approving authority.

7.4.2.1 The maximum allowable maximum longitudinal stress shall be based on the structural wall thickness, not the total wall thickness.

7.5 *Bending Strength:*

7.5.1 A piping system shall be designed for a maximum allowable bending stress not less than the sum of all bending stress due to dead weight, expansion loads, external loads, and any other static or dynamic loads imposed on the piping system.

7.5.2.1 The maximum allowable maximum bending stress shall be based on the structural wall thickness, not the total wall thickness.

7.6 *Beam Stiffness:*

7.6.1 The piping system shall be supported properly to limit the vertical deflection in any part of the piping system to 0.5 in. (12.7 mm).

7.6.2 The calculation of support spacing shall take into account the dead weight of the pipe and its fluid contents as well as any other static external loads.

7.6.2.1 The maximum allowable maximum support spacing shall be based on the structural wall thickness, not the total wall thickness.

7.7 *Temperature:*

7.7.1 The piping system shall meet the design requirements of these guidelines over the range of service temperatures it will experience.

7.7.2 The maximum working temperature should be at least 36°F (20°C) less than the minimum heat distortion temperature (determined according to ISO 75 method A, or equivalent) of the resin or plastic material. The minimum heat distortion temperature should not be less than 176°F (80°C).

7.7.3 Where high or low temperature services are encountered, special attention should be paid to material properties. Material properties such as strength, modulus, etc., will change with temperature, therefore, they shall be modified according to the pipe system's design temperature.

7.8 *Impact Resistance:*

7.8.1 A piping system shall have a minimum resistance to impact to the satisfaction of the approving authority. The impact resistance needs to satisfy all impact loading due to transportation and installation, not just under normal operation.

7.9 *Ageing:*

7.9.1 Before selection of a piping system material, the manufacturer shall confirm that the environmental effects including, but not limited to, ultraviolet rays, saltwater

Copyright by the ASTM International
Wed Feb 02 02:08:30 2005

exposure, oil and grease exposure, temperature, and humidity, will not degrade the mechanical, electrical, or physical properties of the piping system material below the values necessary to meet these guidelines.

7.10 *Fatigue:*

7.10.1 In the cases where design loadings incorporate a significant cyclic or fluctuating component, fatigue shall be considered in the material selection process and taken into account in the installation design.

7.10.2 In addressing material fatigue, the designer may rely on experience with similar materials in similar service or only laboratory evaluation with mechanical test specimens. However, the designer is cautioned that small changes in the material composition may significantly affect fatigue behavior.

7.11 *Erosion Resistance:*

7.11.1 In the cases where fluid in the system has high flow velocities, abrasive characteristics, or where there are flow path discontinuities producing excessive turbulence, the possible effect of erosion shall be considered. If erosion can not be avoided then adequate measures shall be taken such as special liners, change of materials, etc.

7.12 *Fluid Absorption:*

7.12.1 Absorption of fluid by the piping system material shall not cause a reduction of mechanical, electrical, or physical properties of the material below that required by these guidelines.

7.13 *Material Compatibility:*

7.13.1 The piping material shall be compatible with the fluid being carried or in which it is immersed such that its design strength does not degenerate below that recognized by these guidelines. Where the reaction between the pipe material and the fluid is unknown, the compatibility should be demonstrated to the satisfaction of the approving authority.

7.14 *Potable Water Usage:*

7.14.1 The material, including pipe, fittings, and joints shall have no adverse effect on the health of personnel when used for potable water service. The material used for such purposes shall be to the satisfaction of the authority.

7.15 *Electrical Resistance*—Classes C and D pipe and fittings, and F joints and representative systems assembled from such components shall have a resistance per unit length not to exceed 1×10^5 Ω/meter (3.281×10^5 Ω/foot) when tested in accordance with 11.12.

7.16 *Static Charge Shielding*—Classes C and D pipe and fittings and F joints shall have a maximum resulting voltage not to exceed 100 V induced on the exterior surface of the pipe when tested in accordance with 11.13.

7.17 *Grounding Resistance*—Resistance to ground should not exceed 1×10^6 Ω when tested in accordance with 11.14.

7.18 *Flame Spread*—Piping shall have a flame spread index of 25 or less when tested in accordance with 11.9. Nominal 6-inch pipe should be cut into three 2-inch by 18-inch sections, measured along its chord and axially, respectively (19.5°) to approximate the flat 6 inch by 18 inch panel required in Test Method E 162. Edges of each of these sections should be cut so that they are completely flush (0.001″ gap maximum) to each other along the entire length of the sections. Where protective coatings or coverings are used, they shall also be tested while coated on or attached to the pipe sections. The outer surface should be orthogonal to the fire direction. The IMD Assembly Resolution A.753(18) is an alternative test method.

7.19 *Smoke Generation*—The maximum specific optical density under uncorrected flaming and nonflaming conditions for pipe should be 200 when tested in accordance with 11.10. 3 in. by 3 in., measured axially and along its chord (29° segment), square pieces should be cut from 12 in. pipe. Where protective coatings or coverings are used, they shall also be tested while coated or attached to the pipe sections. The outer surface should be orthogonal to the fire direction.

7.20 *Toxic Products of Combustion*—The following gases should have concentrations less than or equal to the limits listed in Table 1 when measured in accordance with Guide E 800 or equivalent during smoke generation (test 3). Samples should be drawn from the smoke chamber either at the point of maximum smoke concentration, or at the end of the test. The point of maximum smoke concentration, or at the end of the test. The point of maximum smoke concentration is explained in Guide E 800. For purposes of sampling, it may be defined as the point in time up to two minutes after the smoke concentration begins to decline or flatten out in a straight line. Burning of the pipe samples shall be done with Test Method E 662.

8. Other Requirements

8.1 *Flanges*—Fiberglass flanges for merchant vessels shall conform to Specification D 4024, ANSI B16.1, and ANSI B16.5.

8.2 *Potable Water Piping Systems*—Fiberglass pipe and fittings to be used on potable water systems must conform with National Sanitation Foundation Standard 14.

8.3 *Conductive Systems and Components:*

8.3.1 Conductive pipes, fittings, and joints meeting this specification and systems constructed thereof are preferred to be homogeneously conductive throughout.

8.3.2 Conductivity may be achieved through the use of conductive layers. In this case, the following applies:

8.3.2.1 Two conductive layers, as a minimum, are required—one on the interior and one on the exterior.

8.3.2.2 Conductive connections between the layers are required to equalize potential between the layers. The resistance of these connections shall meet the requirements of 7.15 and 7.17.

8.3.2.3 Test points must be included that are easily accessible on the exterior surface to permit measurement of the interior layer's resistance per unit length after installation. These test points must be electrically isolated from the exterior conductive layer.

8.3.2.4 The internal and external conductive layers, con-

ductive connections, and test points shall be suitable for the system's intended service and have a lifetime expectation no less than the non-conductive materials of the system.

9. Dimensions and Tolerances

9.1 Dimensions and tolerances of pipe and fittings shall meet the requirements of Annex A6, unless otherwise agreed upon by the buyer and seller.

10. Workmanship, Finish, and Appearance

10.1 The pipe and fittings shall be free from defects including indentations, delaminations, bubbles, pinholes, foreign inclusions, cracks, porosity, and resin-starved areas which, due to their nature, degree, or extent, detrimentally affect the strength, serviceability, and conductivity (as applicable) of the pipe and fittings. The pipe and fittings shall be as uniform as commercially practicable in color, opacity, density, and other physical properties. The pipe and fittings shall be smooth and uniform. All pipe and fittings ends shall be cut at right angles to the axis of the pipe and any sharp edges removed. The bore of each fitting shall have a smooth uniform surface, and protrusion exceeding 1/16 in. (1.6 mm) of material into the internal fittings flow area shall be removed and blended with adjacent smooth surfaces.

11. Test Methods

11.1 *Conditioning*—Condition test specimens at 73 ± 4°F (23 ± 2°C) and 50 ± 5 % relative humidity for not less than 48 h prior to testing, in accordance with Procedure A of Practice D 618, for those tests in which conditioning is required and in all cases of disagreement.

11.2 *Test Conditions*—Conduct tests at ambient temperature and humidity, unless otherwise specified in the test method or in this specification.

11.3 *Sampling*—To determine conformance of the material to the hydrostatic strength requirements of 7.2, take samples of pipe at random on a monthly basis or on each production run, whichever is the most frequent. The rate of sampling for the other tests listed shall be in accordance with accepted statistical practice.

11.4 *Dimensions and Tolerances*—Determine wall thickness, length, diameter, and liner thickness in accordance with Practice D 3567.

11.5 *Hydrostatic Strength*—Determine hydrostatic strength in accordance with Test Method D 1599 (free ends test).

11.6 *Impact Resistance*—Determine impact resistance in accordance with the recommended test method in Annex A1.

11.7 *Beam Stiffness*—Test the pipe samples at a minimum temperature of 240°F (116°C) in accordance with Test Method D 2925. After determining *EI* from the test results, calculate the permissible simple span for 1/2 in. (25 mm) deflection. The calculated span after 1000 h at 240°F (116°C) shall not be less than those given by the manufacturer's literature, assuming the pipe to be full of water.

11.8 *External Pressure Resistance*—Test the pipe samples at 240°F (116°C) in accordance with Test Method D 2924. The failure pressure for the manufacturer's minimum wall thickness shall not be less than three times the rate of external pressure resistance published by the manufacturer's product specifications. Calculate the failure pressure for all pipe sizes of identical construction using the following equation:

$$P = \frac{8K't^3}{(OD - t)^3}$$

where:

P = pressure at collapse or leak, psi (kPa),
K' = KE, psi (kPa),
K = buckling scaling constant determined by Test Method D 2924,
E = circumferential modulus of elasticity as defined in Test Method D 2924,
t = minimum reinforced wall thickness, in. (mm), and
OD = outside diameter of pipe, in. (mm).

11.9 *Flame Spread*—Test samples cut from pipe in accordance with 7.18 and tested per Test Method E 162 or equivalent.

11.10 *Smoke Generation*—Test samples cut from pipe in accordance with 7.19 and tested per Test Method E 662 or equivalent.

11.11 *Toxic Products of Combustion*—Determine the toxic products of combustion during smoke generation test 3 of Test Method E 800 or equivalent.

11.12 *Electrical Resistance Per Unit Length*—Determine electrical resistance in accordance with the recommended test method in Annex A3.

11.13 *Static Charge Shielding Capability*—Determine static charge shielding capability in accordance with the recommended test method in Annex A2.

11.14 *Grounding Resistance*—Determine grounding resistance in accordance with the recommended test method in Annex A2.

11.15 *Longitudinal Tensile Properties*—Determine longitudinal tensile properties in accordance with Test Method D 2105.

12. Inspection and Sampling

12.1 Inspection and sampling of the material shall be in accordance with Practice D 1898 and agreed upon between the purchaser and the supplier as part of the purchase contract.

13. Certification

13.1 *General:*

13.1.1 A producer's certification shall be furnished to the purchaser stating that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements. A report of the test results shall be furnished.

13.2 If the supplier has in his possession bonafide test certification data acceptable to the purchaser, the purchaser may extend initial approval under 13.1 of this specification.

14. Product Marking

14.1 Pipe and fittings shall be marked with the name, brand or trademark of the manufacturer, NPS, weight (type, grade, and class), specification designation, and date and any other information that may be desired for a specific material.

15. Keywords

15.1 epoxy resin fittings; epoxy resin pipe; marine piping; nominal pipe size; thermoset epoxy resin pipe

ANNEXES

(Mandatory Information)

A1. TEST METHOD FOR IMPACT RESISTANCE OF FIBERGLASS PIPE AND FITTINGS BY MEANS OF A FALLING STEEL BALL

A1.1 Scope

A1.1.1 This test method covers the determination of the energy required to produce failure in fiberglass pipe and fittings under specified conditions of impact by means of a falling steel ball. Balls of differing diameter and weight may be used.

A1.2 Significance

A1.2.1 The testing procedures in this test method are applicable over a range of impact energies and ball diameters. The specific ball weight and diameter must be selected for each size and type of product.

A1.2.2 This test method is intended to represent service conditions wherein the product may be subjected to damage from impact by falling objects such as tools. Low-velocity impact, such as that caused by dropping a full length of pipe or fitting for a small distance onto a support surface, may not be accurately represented by this test method.

A1.3 Apparatus

A1.3.1 *General*—One type of impact tester is illustrated in Fig. A1.1.

A1.3.2 *Steel Ball*—Two different balls may be used. The ball designated A is 2.30 in. (58.4 mm) in diameter with a weight of 29.15 oz (826.5 g). The ball designated B has a diameter of 3.00 in. (76.2 mm) and a weight of 63.5 oz (1800 g). Other ball sizes may be used upon agreement between the buyer and the seller.

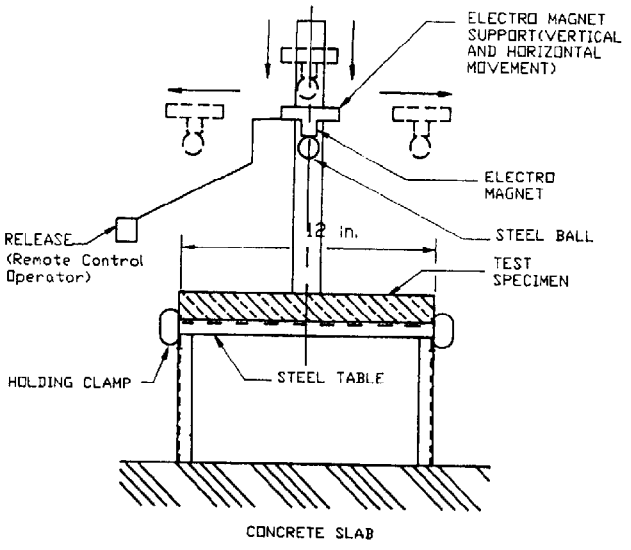

FIG. A1.1 Test Apparatus

A1.3.3 *Support Surface*—The test stand from which the ball is dropped shall be resting firmly on a concrete slab floor.

A1.3.4 *Vertical Drop*—A plump bob shall be used to ensure that the ball will drop squarely on the test specimen when released.

A1.3.5 Drop heights in increments of 1, 2, or 3 in. (25.4, 51, or 76 mm) are normally used. Means shall be provided to hold the ball at the appropriate drop heights above the test specimen as measured from the bottom of the ball to the surface of the specimen, to release the ball in a reproducible manner and to allow the ball to fall freely. Mechanical means may be used to catch the rebounding ball, or it may be caught by hand.

A1.3.6 *Specimen Holder:*

A1.3.6.1 For testing pipe, the specimen shall rest for its full length on a flat steel plate at least 0.5 in. (13 mm) thick.

A1.3.6.2 For testing fittings, a steel saddle plate curved to fit the part may be required to produce line bearing, as, for example, when the ball is being dropped onto the outer radius of a 90° elbow.

A1.3.6.3 Means shall be provided to clamp the specimen firmly into proper position at each end.

A1.4 Test Specimens

A1.4.1 The test specimens of pipe shall be equal in length to the nominal diameter but not less than 12-in. (305-mm) long. If impact resistance can vary along the pipe length, select test specimens from at least three widely spaced locations.

A1.4.2 Fittings shall be tested as a single unassembled unit.

A1.5 Number of Specimens

A1.5.1 The approximate starting point can usually be determined on one preliminary specimen.

A1.5.2 Sufficient specimens shall be used thereafter to produce a minimum of four drops at each of three different drop heights. Usable data are obtained only when, at a given drop height, at least one drop causes a failure and at least one drop does not cause a failure. If usable data are obtained at only one or two of the selected drop heights, reduce the drop height increments and continue testing within the range of heights yielding usable data.

A1.6 Conditioning

A1.6.1 The test specimens shall be conditioned at 73° + 4°F (23° + 3°C) for a minimum of 8 h prior to testing for those tests in which conditioning is required.

A1.6.2 Tests made at other temperatures shall be made in an enclosure maintained at the test temperature.

Copyright by the ASTM International
Wed Feb 02 02:08:31 2005

A1.7 Procedure

A1.7.1 Measure the dimensions of the test specimens in accordance with Practice D 3567. Include measurements of liner thickness and external coating thickness if applicable.

A1.7.2 Mount the specimen so the ball will strike no less than 3 in. (76 mm) from its end. The point of impact shall be at the top of the vertical diameter. Mark the point of impact and drop height on the outside of the specimen with a marking pen.

A1.7.3 Make preliminary tests to determine the approximate height of fall to produce failure in the particular pipe or fitting being tested. At this point it will usually not be necessary to cut the specimen in order to examine the inside surface.

A1.7.4 Select a ball weight and size that will produce failures between NPS 6 and 60. Using additional specimens test at three different drop heights that bracket the approximate height determined previously.

A1.7.5 Pipe less than NPS 2 in diameter are impacted twice at diametrically opposite points. Pipe NPS 2 or more in diameter can be impacted at each cross section a minimum of four times equally spaced around the circumference, using equal drop heights. As permitted by specimen diameter, additional drop points may be used with a circumferential spacing of 3 in. (76 mm). With a specimen 12 in. (305 mm) in length, drops may be made at three different cross sections (at the quarter points).

A1.7.6 For testing fittings, use diametrically opposite drop points or points in a line separated by a minimum of 3 in. (76 mm), depending on specimen geometry. For example, a 90° elbow may be laid on its side and tested at diametrically opposite points every 3 in. (76 mm) along its length, or it may be supported on a curved saddle plate and tested at points every 3 in. (76 mm) along its outer radius.

A1.7.6.1 Impact resistance of certain fittings will be a function of the fitting geometry at the point of impact. For example, testing on a 90° elbow may be limited to drops only on the outside radius when the test results reveal this as the critical area.

A1.7.7 A minimum of four impacts at each of three different drop heights which produce usable data are required (see A5.2).

A1.7.8 After a specimen has been impacted in as many places as permitted herein, cut the specimen lengthwise along its axis to examine the inside surface for failure. If a leakage test is to be performed on the impacted specimen, this can be carried out using water or air prior to cutting. The test pressure shall be 1½ times the rated pressure for the part.

A1.7.9 Swab the inside surface with fluorescent dye and use an ultraviolet light to detect failure. As an alternative, it may be possible to use other dyes or inks to high-light cracks.

A1.8 Definition of Failure

A1.8.1 Failure in the test specimen shall be shattering or any crack or split on the inside that was created by the impact which, when highlighted with dyes or inks, can be seen by the naked eye.

A1.8.2 Leaking of the specimen as a result of impact shall also be defined as failure. Because of difficulty in observing damage on the inside, failure in an unlined pipe or fitting will normally be defined as leakage in a pressure test.

A1.8.3 Damage to an external coating is not considered failure unless agreed upon between the buyer and the seller.

A1.9 Determination of Average and Standard Deviation

A1.9.1 Calculate the percentage of failures at each drop height.

A1.9.2 Plot the percentage of failures versus drop height on probability paper and draw a best-fit line representing the trend of the data. Read off the mean drop height, h_{50}, and drop height standard deviation $h_{50} - h_{15.9\%}$.

A1.9.3 Calculate the impact resistance as ball weight in pounds (newtons) times drop height in feet (meters). Calculate the standard deviation of impact resistance as ball weight times drop height standard deviation.

A1.10 Report

A1.10.1 Report the following information:

A1.10.1.1 Complete identification of the pipe or fitting tested including manufacturer's name and code, NPS, and average wall, liner, and coating thicknesses.

A1.10.1.2 Location of test specimens along pipe length, if applicable.

A1.10.1.3 Atmosphere in which the test was made and conditioning procedure.

A1.10.1.4 Ball diameter and weight.

A1.10.1.5 Average impact resistance in ft·lbf (N·m).

A1.10.1.6 Standard deviation in ft·lbf (N·m).

A1.10.1.7 Point of impact on fittings.

A1.10.1.8 Mode of failure (visible crack or leak) and appearance of impact area.

A1.10.1.9 Results of pressure test if applicable.

A1.10.1.10 Date of test.

A2. TEST METHOD FOR DETERMINING THE STATIC CHARGE SHIELDING CAPABILITY AND SYSTEM RESISTANCE OF REINFORCED THERMOSETTING RESIN PIPE, FITTINGS, AND JOINTS AFTER EXPOSURE TO VARIOUS CHEMICAL ENVIRONMENTS

A2.1 Scope

A2.1.1 This test method determines the static charge, if any, present on the exterior surface of a grounded fiberglass pipe, fitting, or joint when a charge is applied to the interior surface. It is also used to measure the resistance of the associated grounding techniques and to determine the effect of typical chemical exposures on the shielding capability of the pipe and grounding system.

A2.2 Summary of Test Methods

A2.2.1 *Grounding Resistance*—The test method consists of electrically isolating the pipe, fitting, or joint, then grounding the system using its associated grounding technique, and measuring the resistance of the system from an interior surface to a common ground.

A2.2.2 *Static Charge Shielding Capability*—This test method consists of applying a static charge to the interior

Copyright by the ASTM International
Wed Feb 02 02:08:31 2005

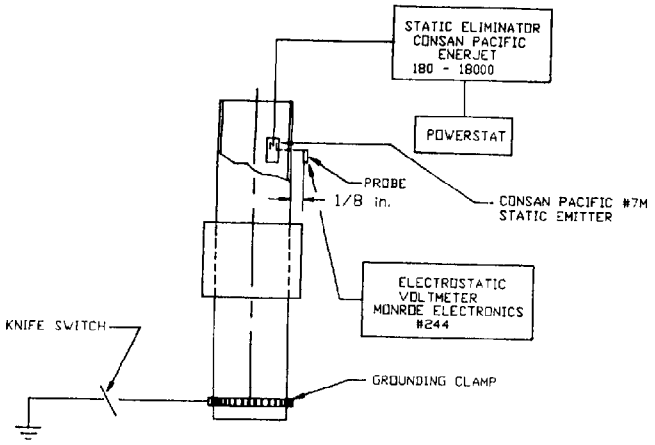

FIG. A2.1 Test Setup

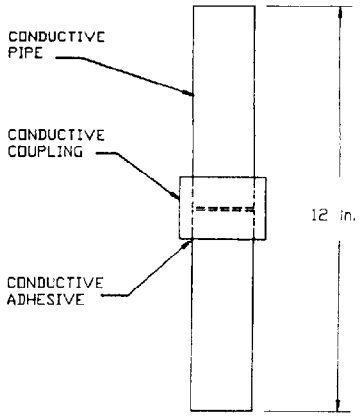

FIG. A2.2 Test Specimens

surface of a grounded reinforced thermosetting resin pipe, fitting, or joint and then measuring the resulting voltage, if any, induced on the exterior surface.

A2.3 Test Equipment (see Fig. A2.1)

A2.3.1 *Static Generator*—An instrument capable of producing clouds of either negative or positive charges having a controlled voltage of 0 to 1000 V.[11]

A2.3.2 *Electrostatic Voltmeter*—An electrostatic voltmeter having a range of 0 to +3000 V and an accuracy of 0.1 %.[12]

A2.3.3 *Exposure Tank*—An exposure tank of nonmetallic construction and resistant to the test environment. It shall be maintained at a temperature of 60 to 80°F (15.6° to 26.7°C) throughout the duration of the test.

A2.3.4 *Oven*—An oven capable of being controlled to a temperature of 150° + 10°F (65.6° + 10°C).

A2.3.5 *Megohmmeter*—A megohmmeter having an accuracy of ±2 %.

A2.4 Test Specimens (see Fig. A2.2)

A2.4.1 *Specimen Size:*

A2.4.1.1 *Diameter*—Unless otherwise specified, the nominal diameter of the pipe, fitting, or joint tested shall be 2 in. (Fig. A2.2).

A2.4.1.2 *Length*—The length of the specimen shall be a minimum of seven times the nominal diameter of the pipe. To achieve this length, additional sections of conductive pipe shall be added as necessary, using the manufacturer's normally recommended assembly methods. If the additional sections are needed, resistance measurements shall be taken across the joints to ensure that the resistance per unit length does not exceed 1×10^5 ohms per meter (3.281×10^5 ohms per foot). The procedures in Annex A3 shall be used.

A2.5 Conditioning

A2.5.1 No special conditioning of the samples prior to initiation of the test is required.

[11] A Static Eliminator has been found to meet these requirements.

[12] An instrument manufactured by Monroe Electronics, Model No. 244, has been found to meet this requirement.

A2.6 Procedure

A2.6.1 Apply a suitable paint-on electrode around the interior circumference of the specimen on the end to which the grounding system will be installed. The distance of the electrode from the end of the specimen shall be greater than or equal to twice the specimen thickness. The width of the electrode shall be greater than four times the specimen wall thickness. Dimensional tolerances of the electrode with and its distance to the end shall not exceed ±10 % separately or combined. Allow the electrode to dry, then install the grounding clamp of the ground system on the exterior of the specimen at one end in accordance with the manufacturer's instructions. Any surface preparation shall not exceed that normally required when assembling a piping system using a fitting. If it is desired to compute surface or volume resistivity, then the procedures in Test Methods D 257 and D 4496 shall be adhered to.

A2.6.2 Position the specimen vertically on a nonconducting surface. Ground the specimen through the grounding system, and using the megohmmeter measure the resistance of the ground system from ground to a position on the interior surface of the electrode. The power applied should neither exceed 1W, nor should the electrification time exceed one min unless otherwise specified. Record the reading of the megohmmeter and its accuracy at that range.

A2.6.3 Thoroughly remove the electrode, then lower the static emitter into the interior of the pipe, fitting, or joint so that it is equidistant from each end. The emitter must be located as close to the interior surface of the pipe, fitting, or joint as possible.

A2.6.4 Approximately ⅛ in. (3.2 mm) from the exterior surface of the pipe, fitting or joint, and opposite the static emitter, position the probe from the electrostatic voltmeter. Fig. A2.1 shows a typical test setup.

A2.6.5 With the specimen ungrounded, turn the static eliminator on and adjust its output via a powerstat to obtain a voltage reading of 2500 permissible deviation (for example, +10 V) on the electrostatic voltmeter.

A2.6.6 Ground the test specimen by closing a switch connecting the test specimen to ground and record the residual voltage.

A2.6.7 If the effect of a chemical on the shielding charac-

Wed Feb 02 02:08:31 2005

teristics of the pipe, fitting, or joint and grounding technique is being studied, place the test specimen in a test tank so that it is completely immersed in the test fluid after initial measurement. Maintain the temperature of the bath at 60° to 80°F (15.6° to 26.7°C) throughout the duration of the test. Suggested test environments include but are not limited to (*1*) salt water per Specification D 1141, (*2*) gasoline, (*3*) Bunker C, and (*4*) 1 % sulfuric acid.

A2.6.8 At the end of 1, 3, 6, and 12 months, remove the test specimen from the bath and rinse thoroughly with tap water if the specimen has been exposed to a water-soluble product or a hydrocarbon solvent if the specimen has been exposed to a petroleum product.

A2.6.9 Wipe dry and place the test specimen in an oven at 150 + 10°F for a period of 2 h.

A2.6.10 At the end of 2 h, remove the specimen from the oven and allow it to cool to 70° to 80°F (21.1° to 26.7°C) in a 50 ± 5 % relative humidity environment for 60 ± 5 min before retesting.

A2.6.11 Repeat A2.6.1 through A2.6.6.

A2.6.12 Note the appearance of the test specimens and the condition of the grounding clamp.

A2.7 Report

A2.7.1 Report the following information:

A2.7.1.1 Manufacturer of pipe, fitting, or joint.

A2.7.1.2 Designation of product being tested.

A2.7.1.3 Description of the test sample including diameter of pipe, fitting, or joint and lengths of pipe extenders (when needed).

A2.7.1.4 Description of grounding details.

A2.7.1.5 Initial resistance reading of grounding system and accuracy and those before and after exposure periods of 1, 3, 6, and 12 months when the exposure periods are used.

A2.7.1.6 Test media.

A2.7.1.7 Initial exterior voltage readings before and after grounding and the exterior voltage reading before and after grounding following exposure periods of 1, 3, 6, and 12 months when the exposure periods are used.

A2.7.1.8 Appearance of test specimen.

A2.7.1.9 Date of test.

A3. TEST METHOD FOR DETERMINING THE ELECTRICAL RESISTANCE PER UNIT LENGTH OF FIBERGLASS PIPE, FITTINGS, AND JOINTS AND REPRESENTATIVE PIPING SYSTEMS AFTER EXPOSURE TO VARIOUS CHEMICAL ENVIRONMENTS

A3.1 Scope

A3.1.1 This test method covers the determination of the electrical resistance per unit length of conductive pipe, fittings, and joints in air before and after exposure to various chemical environments and the electrical resistance per unit length in air of a representative piping system assembled from such components. The components and systems are hereafter referred to in this Annex as the specimen.

A3.2 Summary of Test Method

A3.2.1 In this test method, the length of the potential current path is measured and then a potential difference of 1500 V is applied across the test specimen and a resistor of known value, which are connected in series. The voltage drop across the test specimen is then accurately measured and the resistance of the specimen calculated followed by calculation of resistance per unit length. Figure A3.1 shows a drawing of a typical test setup.

A3.3 Significance

A3.3.1 This test method is suitable for measuring resistance between 2 and 1×10^{10} Ω using an applied voltage of 1500 V.

A3.4 Test Equipment

A3.4.1 *Exposure Tank*—An exposure tank of nonmetallic construction and resistant to the environment being tested. It shall be maintained at a temperature of 60° to 80°F (15.6° to 26.7°C) throughout the duration of the test.

A3.4.2 *Oven*—An oven capable of being controlled to a temperature of 150° ± 10°F (66.6 ± 10°C).

A3.4.3 *Voltmeter*—A voltmeter capable of measuring dc voltages between 0.0001 and 1500 V with a resolution of 0.005 %.[13]

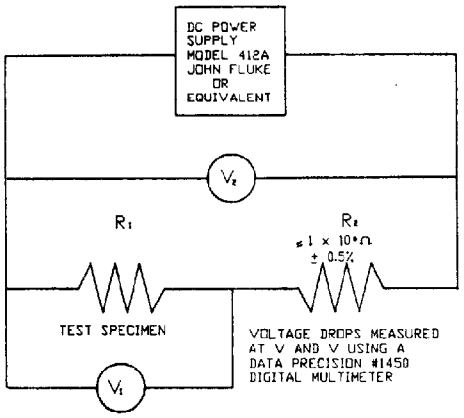

FIG. A3.1 Test Setup for Determining the Electrical Resistance of Fiberglass Pipe and Fittings

A3.4.4 *dc Power Supply*—A constant voltage dc power supply capable of supplying 1500 V at a current of 0.5 mA.

A3.4.5 *A 1 × 10⁶* ± 0.5 % × 1 watt resistor.

A3.5 Test Specimens

A3.5.1 *Pipe, Fittings, and Joints:*

A3.5.1.1 *Diameter*—Unless otherwise specified, the nominal diameter of the pipe, fitting, or joint tested shall be 2 in.

A3.5.1.2 *Length*—The length of the specimen shall be six times the nominal diameter of the product plus two times the width of the grounding clamps. To achieve this length,

[13] A Data Precision Model No. 1450 Digital Multimeter has been found satisfactory for this purpose.

Copyright by the ASTM International
Wed Feb 02 02:08:32 2005

additional sections of conductive pipe shall be added using the manufacturer's normally recommended assembly methods.

A3.5.2 *Representative Piping Systems:*

A3.5.2.1 *Diameter*—Unless otherwise specified the nominal diameter of the system tested shall be 2 inches.

A3.5.2.2 *Length*—The minimum length shall meet the requirements of A3.5.1.2.

A3.6 Conditioning

A3.6.1 No special conditioning of the specimens prior to initiation of the test is required.

A3.7 Procedure

A3.7.1 *Potential current path selection:*

A3.7.1.1 *Pipes, straight joints, adapters, couplings, plugs, caps, and bushings*—The path length shall be parallel to the centerline axis of the component and shall encompass the length of the component.

A3.7.1.2 *Elbows*—Two path lengths shall be established, one on the outer and one on the inner radius of curvature.

A3.7.1.3 *Crosses*—Six path lengths shall be established, one parallel to each of the longitudinal centerline axes and one along the shortest path from adjacent openings through each 90° bend.

A3.7.1.4 *Tees*—One path shall parallel the centerline axis opposite the interior opening. Two additional paths shall also be established, one along the shortest path from adjacent openings through each 90° bend.

A3.7.1.5 *Laterals*—Three paths shall be established, one parallel to the longitudinal centerline axis, one along the shortest distance between adjacent openings through the oblique angle, and one along the shortest distance between adjacent openings through the obtuse angle.

A3.7.1.6 *Representative piping systems*—The path length shall encompass the longest possible length that parallels the centerline axis of the system.

A3.7.1.7 If extenders are used, both lengths shall incorporate that portion of the extenders needed to meet specimen length requirements.

A3.7.1.8 For components and systems achieving conductivity through use of conductive layers, the resistance per unit length will be measured as follows:

(*a*) Separately through each conductive layer using the path selection criteria in paragraphs A3.7.1.1 through A3.7.1.7.

(*b*) Through the conductive connections between layers. The path length shall consist of the distance between the clamps plus the thickness of the non-conductive portion of the pipe, fitting, or joint. The path shall be measured from the interior of one end through the joint to the exterior of the opposite end.

(*c*) From the exterior part of the test point separately to the interior of each end of the pipe, joint, or fitting.

A3.7.2 *Sample Preparation*—Install the grounding clamps for each potential current path of interest in accordance with the manufacturer's recommendations. In the case of pipes having conductive layers, the recommendations will include methods/equipment that accommodate the separate resistance measurements of inner and outer conductive layers, conductive connections between layers, and resistance of interior layer test points. The surface preparation in any case shall not exceed that normally required when assembling a piping system using a fitting. The distance between the clamps should be six times the nominal diameter of the pipe, fitting, or joint when testing individual components and systems. If a specimen ends with an open flange, the grounding clamp will be installed on the face of the flange.

A3.7.3 Measure the lengths of the potential current paths of interest for test specimen including extenders (if used) and the thickness of any exposed flange faces.

A3.7.4 Isolate the test specimen from ground.

A3.7.5 Connect a $1 \times 10^6\ \Omega - 1$ W resistor in series with the test specimen.

A3.7.6 Apply a dc voltage of 1500 ± 0.1 V across the test specimen and resistor.

A3.7.7 Measure the voltage drop, V_1, across the test specimen. If immersion is not required, calculate the resistance in accordance with A3.7.14.

A3.7.8 If immersion is requested by the purchaser, place the specimens in the test tank so that they are completely immersed in the test fluid. Maintain the temperature of the bath at 60° to 80°F (15.5° to 26.7°C) throughout the duration of the test. Suggested test environments are: (1) Salt water per Specification D 1141, (2) Gasoline, (3) Bunker C, and (4) 1 % sulfuric acid.

A3.7.9 At the end of 1, 3, 6, and 12 months, remove the test specimens from the bath and rinse thoroughly with tap water if the test specimens have been exposed to a water soluble product or a hydrocarbon solvent if the specimens have been exposed to a petroleum product.

A3.7.10 Place the test specimens in an oven at 150° ± 10°F (66.6° ± 10°C) for a period of 2 h.

A3.7.11 At the end of 2 h, remove the specimens from the oven and allow them to cool to 70° to 80°F (21.1° to 26.7°C) in a 50 ± 5 % relative humidity environment for 60 ± 5 min before retesting.

A3.7.12 Remeasure the voltage drop across the specimens in accordance with A3.7.5 through A3.7.7.

A3.7.13 Note the appearance of the test specimens and the conditions of the clamps.

A3.7.14 Using the information obtained, calculate the resistance of the test specimen before and after exposure using the following equation:

$$\frac{V_1}{R_1} = \frac{V_2}{R_1 + R_2}$$

where:

V_1 = voltage drop across specimen,
R_1 = resistance of test specimen,
V_2 = line voltage (1500 V), and
R_2 = value of known resistor ($1 \times 10^6\ \Omega$).

A3.7.15 Calculate the resistance per unit length for each of the potential current paths of interest on the specimen and its associated resistance.

A3.8 Report

A3.8.1 Report the following information:

A3.8.1.1 Manufacturer of the specimen.

A3.8.1.2 Designation of product being tested.

A3.8.1.3 Description of the specimen including the diameter and length for a pipe, fitting, or joint (including the

Copyright by the ASTM International
Wed Feb 02 02:08:32 2005

lengths of extensions, if applicable) or a dimensioned sketch for a representative piping system. In both cases, placement of the grounding clamps and the potential current paths and their lengths shall be identified.

A3.8.1.4 Description of grounding clamps and grounding procedure.

A3.8.1.5 Test media.

A3.8.1.6 Initial resistance per unit length between clamps for each potential current path and resistance per unit length for each potential current path at 1, 3, 6, and 12 months if immersion testing was conducted.

A3.8.1.7 Appearance of test specimen if immersion testing was conducted.

A3.8.1.8 Date of test.

A4. TEST METHOD FOR FIRE ENDURANCE EVALUATION OF PLASTIC PIPING IN THE DRY CONDITION

A4.1 Scope

A4.1.1 This test method covers the determination of the fire endurance of thermosetting resin fiberglass pipe, fittings, and joints to be used in marine applications when empty. This test procedure is based on the IMO Assembly Resolution A.753(18) which is an alternative to this test. SI units shall be used in referee decisions.

A4.2 Significance

A4.2.1 This testing procedure in this test method is applicable over a range of temperatures up to 2012°F (1100°C). This temperature rise occurs in less than 1 hour, simulating a fully developed liquid hydrocarbon fire. This test is valid for pipe 1 in. to 48 in. nominal diameters for pressures up to 225 psi.

A4.3 Test Equipment

A4.3.1 *Furnace*—Test furnace with the capability to increase its temperature to 2012°F (1100°C) within 1 h while meeting the accuracy in A4.6.4.1. Furnace shall have a temperature gauge capable of measuring temperature ±2 %.

A4.3.2 *Thermocouples*—Two thermocouples capable of measuring up to 2012°F (1100°C).

A4.3.3 Nitrogen tank with regulator.

A4.4 Test Specimen

A4.4.1 The test specimen should be prepared with the joints, fittings, and fire protection coverings intended for use in the proposed application.

A4.4.2 The number of specimens shall be sufficient to test typical joints and fittings including joints between non-metal and metal pipes and fittings to be used.

A4.4.3 The ends of the specimen shall be closed with one end allowing pressurized nitrogen to be connected.

A4.4.4 The pipe ends and closures may be outside the furnace.

A4.4.5 The general orientation of the specimen should be horizontal and it should be supported by one fixed support with the remaining supports allowing free movement.

A4.4.6 The free length between supports should not be less than 8 times the pipe diameter.

A4.4.7 Full scale fire test shall be performed on 1, 2, 4, and 8 inch pipe systems. Above 8-inch, every third size of the manufacturer's product line shall be tested.

TABLE A4.1 Time/Mean Temperature Ramp of Furnace

Time	Mean Temperature
at the end of: 5 minutes:	≥945°C
at the end of: 10 minutes:	≥1033°C
at the end of: 15 minutes:	≥1071°C
at the end of: 30 minutes:	≥1098°C
at the end of: 60 minutes:	≥1100°C

A4.5 Test Conditions

A4.5.1 *Fire-Protective Coatings:*

A4.5.1.1 If the fire protective coating contains, or is liable to absorb, moisture the specimen should not be tested until the insulation has reached an air-dry condition. This condition is defined as equilibrium with an ambient temperature of 50 % relative humidity at 70 ± 10°F (20 ± 5°C).

A4.5.1.2 Accelerated conditioning is permissible provided the method does not alter the properties of component materials.

A4.5.1.3 Special samples shall be used for moisture content determination and conditioned with the test specimen. These samples should be so constructed as to represent the loss of water vapor from the specimen by having similar thickness and exposed faces.

A4.5.2 A nitrogen pressure inside the test specimen should be maintained automatically at 0.7 ± 0.1 bar during the test. Means should be provided to record the pressure inside the pipe and the nitrogen flow into and out of the specimen in order to indicate leakage.

A4.5.3 *Flame Temperature:*

A4.5.3.1 The exterior flame temperature shall be measured by means of two thermocouples mounted not more than 1 in. (2.5 cm) from the pipe near the center span of the assembly.

A4.5.3.2 The thermocouples shall be mounted on the horizontal plane at the level of the pipe.

A4.5.3.3 The test temperature shall be taken as the average of the two thermocouple readings.

A4.6 Procedure

A4.6.1 Measure the dimensions of the specimen in accordance with Practice D 3567. Include measurements of liner thickness and external coatings, if applicable.

A4.6.2 Place specimen in the furnace.

A4.6.3 Pressurize specimen with nitrogen maintaining the pressure in accordance with A4.5.2.

A4.6.4 Time/mean temperature ramp of furnace according to Table A4.1 is started.

A4.6.4.1 The accuracy of the furnace control should be as follows:

(*a*) During the first 10 min. of the test the area under the curve of mean furnace temperature vs. time should not vary by more than ±15 % of the area under the standard curve.

(*b*) During the first half hour of the test the area under the curve of mean furnace temperature vs. time should not vary by more than ±10 % of the area under the standard curve.

Copyright by the ASTM International
Wed Feb 02 02:08:33 2005

(*c*) For any ten minute period after the first half hour of the test the area under the curve of mean furnace temperature vs. time should not vary by more than ±5 % of the area under the standard curve.

(*d*) At any time after the first 10 min of the test the mean furnace temperature should not differ from the standard curve by more than ±100°C.

A4.6.5 The mean temperature and exterior flame temperature shall be recorded a minimum of once every 30 s.

A4.7 Acceptance Criteria

A4.7.1 No nitrogen leakage from the sample should occur during the test.

A4.7.2 *Hydrostatic Pressure:*

A4.7.2.1 After termination of the furnace test, the specimen together with fire protection coating, if any, should be allowed to cool in still air to ambient temperature and then test to the rated pressure of the pipe.

A4.7.2.2 The pressure should be held for a minimum of 15 min without leakage.

A4.7.2.3 Where practicable, the hydrostatic test should be conducted on bare pipe, that is pipe without any covering, including fire protection. This is to make any leakage readily apparent.

A4.8 Report

A4.8.1 Report the following information:

A4.8.1.1 Complete identification of the pipe or fitting tested including manufacturer's name and code.

A4.8.1.2 Description of fire-protective coating if applicable.

A4.8.1.3 Diameter of pipe, fitting or joint.

A4.8.1.4 Endurance time.

A4.8.1.5 Appearance of test specimen.

A4.8.1.6 Date of test.

A5. TEST METHOD FOR FIRE ENDURANCE TESTING OF WATER-FILLED PLASTIC PIPING

A5.1 Scope

A5.1.1 This test method covers the determination of the fire endurance of thermosetting resin fiberglass pipe, fittings and joints to be used in marine applications when in the wet condition. This test procedure is based on the IMO Assembly Resolution A.753(18) which is an alternative to this test. SI units shall be used in referee decisions.

A5.2 Summary of Test Method

A5.2.1 This test method subjects a pipe sample to a constant 36,011 Btu/(hr-ft·2) (113.6 kW/m·2) net flux to determine a pipe systems fire-endurance.

A5.3 Significance

A5.3.1 This test is valid for pipe 1 in. to 48 in. nominal diameters for pressures up to 225 psi. It will give a purchaser of fiberglass pipe the ability to determine the fire resistance of a fiberglass piping system when filled with water.

A5.4 Test Equipment

A5.4.1 *Sivert No. 2942 burner* or equivalent which produces an air mixed flame.

A5.4.1.1 The inner diameter of the burner heads should be 1.5 in. (29 mm) (see Fig. A5.1).

A5.4.1.2 The burner heads should be mounted in the same plane and supplied with gas from a manifold.

A5.4.1.3 If necessary, each burner should be equipped with a valve in order to adjust the flame height.

A5.4.1.4 The height of the burner stand should also be adjustable.

A5.4.1.5 It should be mounted centrally below the test pipe with the rows of burners parallel to the pipe's axis.

A5.4.1.6 The distance between the burner heads and the pipe should be maintained at 5 ± 3/8 in. (12.5 ± 1.0 cm) during the test.

A5.4.1.7 The free length of the pipe between its supports should be 31.5 ± 2 in. (0.80 ± 0.05 m).

A5.4.2 *Thermocouples*—Two thermocouples capable of

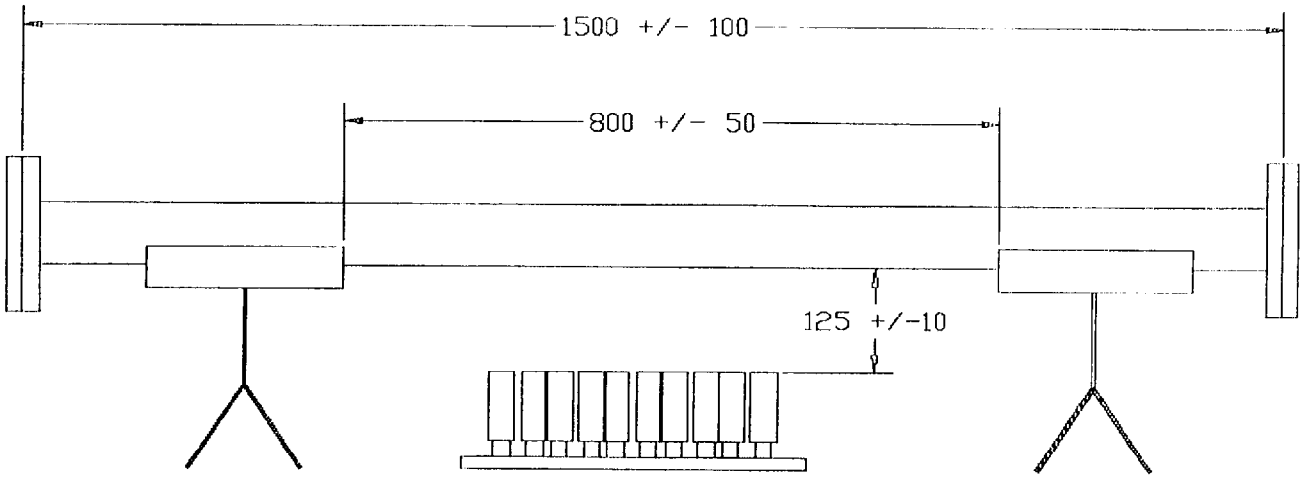

FIG. A5.1 Stand with Mounted Sample

Copyright by the ASTM International
Wed Feb 02 02:08:33 2005

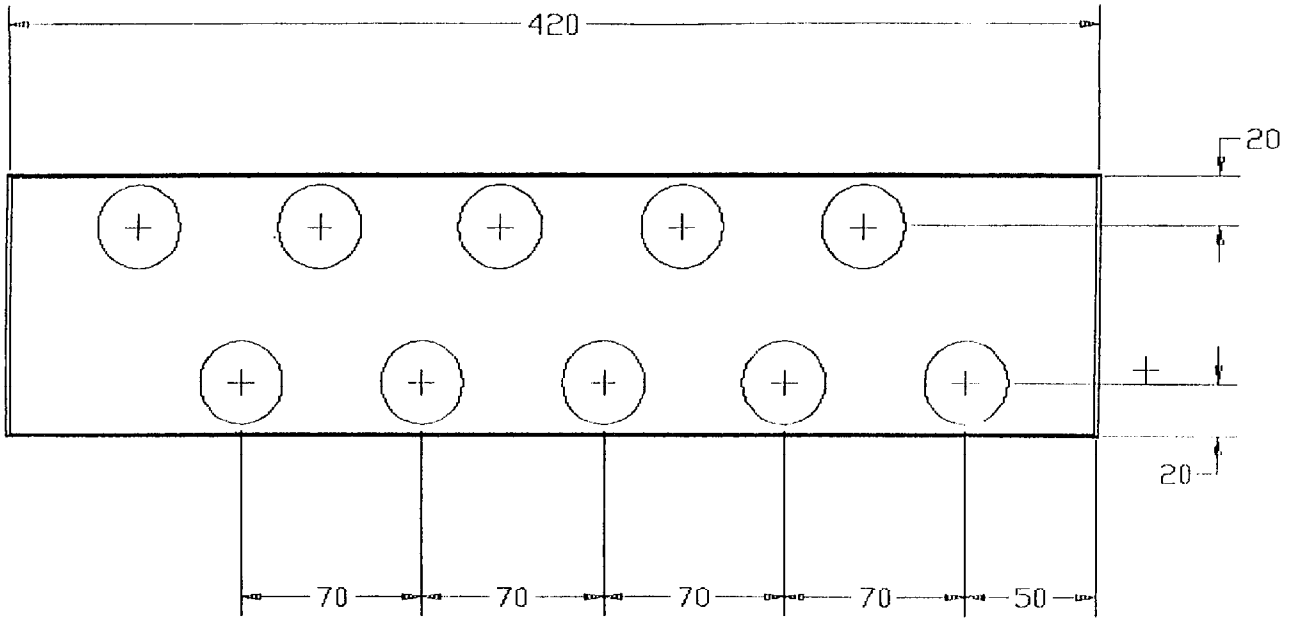

FIG. A5.2 Top View Burner Assembly

measuring up to 2012°F (1100°C).

A5.4.3 *Deaerated water.*

A5.4.4 *Thermometer*—To measure internal water temperature.

A5.4.5 *Pressure Gauge*—Capable of reading up to 5 bars (±5 %).

A5.4.6 *V-Shaped Pipe Supports.*

A5.5 Test Specimen

A5.5.1 *Specimen Length:*

A5.5.1.1 The test specimen should have a length of 59 in. (1.5 m).

A5.5.2 Test specimen should be pipe with permanent joints or fittings intended for use in marine applications.

A5.5.3 All joint types should be tested as they are the primary point of failure.

A5.5.4 The number of pipe specimens should be sufficient to test all typical joints and fittings.

A5.5.5 The ends of each specimen must be closed.

A5.5.6 One end should allow pressurized water to be connected.

A5.5.7 A pressure relief valve should be connected to one of the end closures of each specimen.

A5.6 Test Conditions

A5.6.1 *Fire-Protective Coatings:*

A5.6.1.1 If the fire-protective coating or covering contains, or is liable to absorb, moisture, the test specimen should not be tested until the insulation has reached an air-dry condition. This condition is defined as equilibrium with an ambient temperature of 50 % relative humidity at 70 ± 10°F (20 ± 5°C).

A5.6.1.2 Accelerated conditioning is permissible provided the method does not alter the properties of component materials.

A5.6.1.3 Special samples shall be used for moisture content determination and conditioned with the test specimen. These samples should be so constructed as to represent the loss of water vapor from the specimen by having similar thickness and exposed faces.

A5.6.2 The test should be carried out in a sheltered test site in order to prevent any draft influencing the test.

A5.6.3 Each pipe specimen should be completely filled with deaerated water and vented to exclude air bubbles.

A5.6.3.1 The water temperature should not be less than 59°F (15°C) at the start and should be measured continuously during the test.

A5.6.3.2 The water inside the sample should be stagnant and the pressure maintained at 3 ± 0.5 bar during the test.

A5.6.4 *Flame Temperature:*

A5.6.4.1 The exterior flame temperature shall be measured by means of two thermocouples mounted not more than 1 in. (2.5 cm) from the pipe near the center span of the assembly.

A5.6.4.2 The thermocouples shall be mounted on the horizontal plane at the level of the pipe.

A5.6.4.3 The test temperature shall be taken as the average of the two thermocouple readings.

A5.7 Procedure

A5.7.1 Measure the dimensions of the specimen in accordance with Practice D 3567. Include measurements of liner thickness and external coatings, if applicable.

A5.7.2 Place specimen on two V-shaped supports. The supports may consist of two stands as shown in Fig. A5.1.

A5.7.3 Pressurize specimen with water maintaining conditions in accordance with A6.3.

A5.7.4 *Burner Configuration for Constant Heat Flux:*

A5.7.4.1 For piping 6 ins. and less in diameter, the fire source should consist of two rows of 5 burners as shown in Fig. A5.2.

A5.7.4.2 A constant heat flux averaging 36,011 Btu/(hr-ft·2) (113.6 kW/m·2) (±10 %) should be maintained 5 ± 3/8 in. (12.5 ± 1.0 cm) above the centerline of the array.

Copyright by the ASTM International
Wed Feb 02 02:08:33 2005

(*a*) This flux corresponds to a pre-mix flame of propane with a fuel flow rate of 11.02 lb/hr (5 kg/hr) for a total heat release of 221,780 btu/hr (65 kW).

(*b*) The gas consumption should be measured with an accuracy of at least ±3 % in order to maintain a constant heat flux.

A5.7.4.3 For piping greater than 6 in. in diameter, one additional row of burners should be included for each 2 inch increase in pipe diameter.

(*a*) A constant heat flux averaging 36,011 Btu/(hr-ft·2) 113.6 kW/m·2 (±10 %) should still be maintained at the 5 ± 3/8 in. (12.5 ± 1.0 cm) height above the centerline of the burner array.

(*b*) The fuel flow should be increased as required to maintain the designated heat flux.

A5.7.5 Begin heat flux.

A5.7.6 Record test temperature, water temperature, water pressure at least once every 30 s.

A5.8 Acceptance Criteria

A5.8.1 No leakage from the sample(s) should occur except that slight weeping from the wall may be accepted.

A5.8.2 *Hydrostatic Pressure:*

A5.8.2.1 After termination of the burner regulation test, the test sample, together with the fire protection coating, if any, should be allowed to cool to ambient temperature and then tested to the rated pressure of the pipe.

A5.8.2.2 The pressure should be held for a minimum of 15 min and produce a leakage of less than 0.05 gpm (0.2 liters/min).

A5.8.2.3 Where practical, the hydrostatic test should be conducted on bare pipe that has had all of its coverings, including fire protection insulation removed, so that leakage will be readily apparent.

A5.9 Report

A5.9.1 Report the following information:

A5.9.1.1 Complete identification of the pipe, fitting or joint tested including manufacturer's name and code.

A5.9.1.2 Description of fire-protective coating if applicable.

A5.9.1.3 Diameter of pipe, fitting or joint.

A5.9.1.4 Endurance time.

A5.9.1.5 Appearance of test specimen.

A5.9.1.6 Date of test.

A6. DIMENSIONS AND TOLERANCES

A6.1 For Pipe

A6.1.1 *Diameter*—Pipe meeting this specification shall conform to the requirements in Table A6.1 or Table A6.2. Dimensions shall be determined in accordance with 11.4.

A6.1.2 *Wall Thickness*—The minimum wall thickness of pipe furnished under this specification shall not, at any point, be less than:

A6.1.2.1 Eighty-five percent of the nominal wall thickness published in the manufacturer's literature current at the time of purchase when measured in accordance with 11.4.

A6.1.2.2 The wall thickness determined using hydrostatic design basis in accordance with 7.2.

A6.1.3 *Liner thickness*—Except for unlined products, all pipe shall have a minimum liner thickness of 0.010 in. (0.254 mm) when measured in accordance with 11.4.

A6.1.4 *Length*—Pipe shall be in lengths as specified by

the purchase order when measured in accordance with 11.4.

A6.2 For Fittings

A6.2.1 *Wall thickness*—The minimum wall thickness of fittings furnished under this specification shall not, at any point, be less than the pipe nominal wall thickness published in the manufacturer's literature current at the time of purchase when measured in accordance with 11.4.

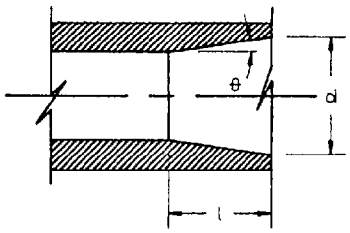
A6.2.2 Except for unlined products, the fittings shall have a minimum liner of 0.010 inches (0.254 mm) when measured in accordance with 11.4.

A6.2.3 *Length*—Lengths and tolerances are specified in Figs. A6.1 through A6.16.

NOTE 1—Outside diameters other than those listed in Table A6.1 or inside diameters as listed in Table A6.2 shall be permitted upon agreement between the manufacturer and the purchaser.

NOTE 2—Outside diameters approximate those for iron pipe size, ISO International Standard 559-1978, and for cast iron pipes, ISO International Standard 13-1978, as follows:

NOTE 3—Tolerances for 1 to 16 NPS in accordance with Specification D 2996 Figures. Tolerances for 18 to 36 NPS are ±1 % of the pipe outside diameter in accordance with ISO 559-1978.



NPS	Socket Entrance Diameter, min, d, in. (mm)	Minimum Effective Bond Length, min, L, in. (mm)	Taper Angle Range ° (Degrees)
1	1.335 (34)	0.750 (19)	1 to 3
1½	1.910 (76)	0.750 (19)	1 to 3
2	2.375 (60)	1.000 (25)	1 to 2
3	3.500 (89)	1.125 (29)	1 to 2
4	4.500 (114)	1.250 (32)	1 to 2
6	6.600 (168)	1.500 (38)	1 to 2
8	8.635 (219)	2.000 (51)	1 to 2
10	10.700 (272)	2.125 (54)	1 to 2
12	12.670 (322)	2.250 (57)	1 to 2
14	14.400 (366)	2.500 (64)	1 to 2
16	16.460 (418)	2.500 (64)	1 to 2

NOTE 1—*Standard tapered socket.* In all cases, the base angle for bells (sockets) shall be the same as the angle for the pipe spigots (male tapers). The tolerances shall be set to ensure there is no gap between the end of the spigot and the bottom of the bell. The minor I.D. (diameter at the bottom) of the tapered socket shall always be less than the end dimension (the diameter at the end) of the pipe spigot to ensure that the spigot does not insert beyond the tapered portion of the bell. The insertion of the spigot into the bell shall be at least equal to the minimum allowable effective bond length (EBL) shown for Fig. A6.2. The minimum effective bond length is the minimum insertion length where the tapered spigot surfaces are in contact with the tapered bell surfaces. The tolerances shall be set to ensure that the effective bond length is at least equal to the values in Fig. A6.2. Angle tolerance for male tapers (spigots) and for female tapers (bells) shall not vary more than 0.25° i.e. the most extreme mismatch in a bonded joint must never exceed 0.5°. For all bonded joints, the angle for the spigot shall be equal to or less than the bell angle (preventing a gap between the end of the spigot and the bottom of the bell).

NOTE 2—Fiberglass fittings and pipe can be connected by flanges or mechanical couplings, or both (that is, grooved or compression type).

FIG. A6.2 Standard Taper-to-Taper Joint

A6.2.4 The lengths and tolerances of fittings not covered in Annex A6 must be agreed upon by the purchaser and the supplier.

The American Society for Testing and Materials takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, 1916 Race St., Philadelphia, PA 19103.

Erratum to ANSI/AWWA C110/A21.10-98 Standard for Ductile-Iron and Gray-Iron Fittings, 3 In. Through 48 In. (76mm Through 1,219 mm) For Water

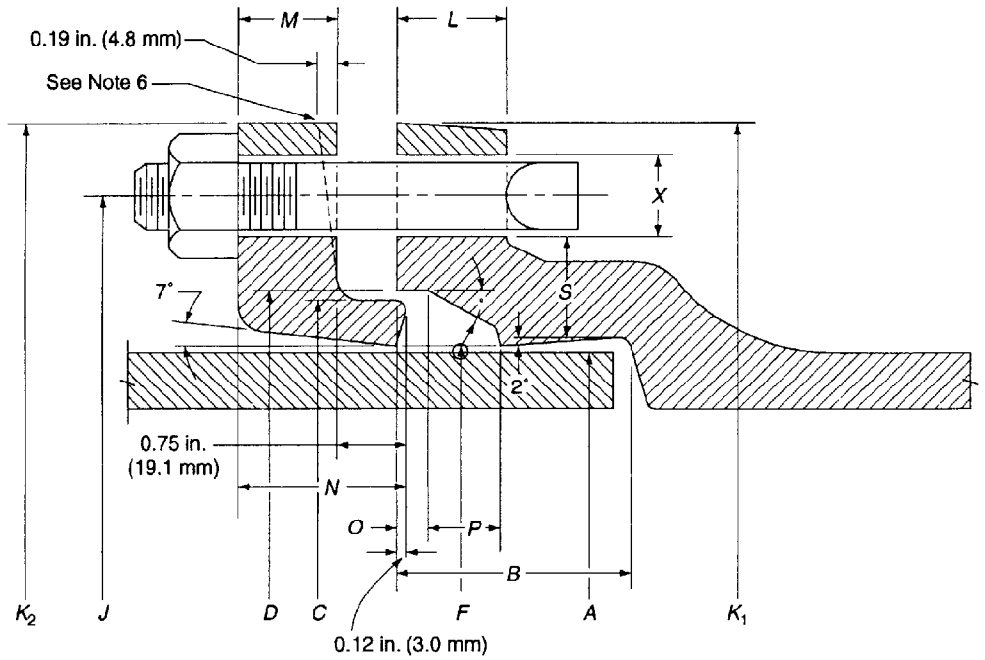
(October 1999)

Correction to figure and table:

P.9, Fig. 1, The arrow head for the "F" dimension needs to be raised so that it touches the dimension line extending between the minimum internal diameters of the gland and the ball socket. (See following Figure)

P.10, Table 1, Bolt lengths for the 42- and 48-inch sizes should read 6½ inches not 6 inches. (See following Table)

Copyright by the American Water Works Association
Wed Feb 02 02:11:14 2005



NOTES:

1. The nominal thickness *S* shall not be less than the nominal thickness of the fitting of which it is a part.
2. The diameter of cored holes may be tapered an additional 0.06 in. (1.5 mm).
3. Dimension *A* in Table 1 is the outside diameter of the plain end of the fitting.
4. In the event of an ovalness to the outside diameter of the plain end, the mean diameter measured by a circumferential tape shall not be less than the minimum diameter shown in Table 1. The minor axis shall not be less than the foregoing minimum diameter plus an additional minus tolerance of 0.04 in. (1.0 mm) for sizes 8–12 in. (203–305 mm), 0.07 in. (1.8 mm) for sizes 14–24 in. (356–610 mm), and 0.10 in. (2.5 mm) for sizes 30–48 in. (762–1,219 mm).
5. K_1 and K_2 are the dimensions across the centerline of the bolt holes. The gray-iron gland and bell flange may be round or polygon in shape for all sizes or square for 3-in. (76-mm) and 4-in. (100-mm) sizes. Ductile-iron glands may be other shapes as long as the gland meets the performance requirements specified in Sec. 4.5, ANSI/AWWA C111/A21.11.
6. Gland thickness *M* for sizes 14–48 in. (356–1,219 mm) may be tapered as shown, at the option of the manufacturer.
7. For ductile-iron glands, the gland thickness *M* listed above is not applicable. Designs incorporating reduced metal-section thicknesses are permitted provided tests with these glands meet the performance requirements of Sec. 4.5, ANSI/AWWA C111/A21.11. Conformance with *N* dimensions shown in Table 1 is required at the bolt holes for all glands, gray iron or ductile iron, to ensure interchangeability of joint parts.

*Dimension details of bell are shown in Figure 1.

†Bolt lengths shown for the 8-in. through 16-in. sizes are ½ in. longer than ANSI/AWWA C153/A21.53-88 bolts for use with ANSI/AWWA C153/A21.53 fittings for these sizes. These longer ANSI/AWWA C111/A21.11 bolts, shown in the table above, may also be furnished with compact fittings in sizes 8–16 in. with the bolt thread length as shown in Figure 3 and Figure 4 of ANSI/AWWA C111/A21.11.

‡For ductile-iron glands, the flange thickness *M* listed above is not applicable. Designs incorporating reduced metal-section thicknesses are permitted provided tests with these glands meet the performance requirements of Sec. 4.5 of ANSI/AWWA C111/A21.11. Conformance with *N* dimensions shown in Table 1 is required for all glands, gray iron or ductile iron, to ensure interchangeability of joint parts.

NOTE: Metric conversions: Dimension: in. × 25.4 = mm.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

All rights reserved. No part of this publication may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopy, recording, or any information or retrieval system, except in the form of brief excerpts or quotations for review purposes, without the written permission of the publisher.

Foreword

This foreword is for information only and is not a part of ANSI/AWWA C110/A21.10.

I. Introduction.

I.A. *Background.* American National Standards Committee A21 on Cast-Iron Pipe and Fittings was organized in 1926 under the sponsorship of the American Gas Association (A.G.A.), the American Society for Testing and Materials (ASTM), the American Water Works Association (AWWA), and the New England Water Works Association (NEWWA). Between 1972 and 1984, the cosecretariats were A.G.A., AWWA, and NEWWA, with AWWA serving as administrative secretariat. In 1984, the committee became an AWWA committee with the name AWWA Standards Committee A21 on Ductile Iron Pipe and Fittings. In 1988, NEWWA withdrew as a separate secretariat; however, it continues to maintain its representation on the A21 Committee. In 1997, A.G.A. withdrew as cosecretariat.

The present scope of Committee A21 activity is the preparation of standards for cast-iron and ductile-iron pressure pipe for gas, water, and other liquids, and fittings for use with such pipe. These standards include design, dimensions, materials, coatings, linings, joints, accessories, and methods of inspection and testing.

The work of Committee A21 is conducted by subcommittees. The scope of Subcommittee 3, Fittings, includes the periodic review of all current A21 standards for fittings and the preparation of revisions and new standards, when needed, for fittings to be used with cast-iron and ductile-iron pressure pipe included in A21 standards.

I.B. *History.* The evolution of AWWA and ANSI standards for fittings is presented in this foreword to provide information relating to systems having aged cast-iron pipe and fittings still in service.

The earliest record of an AWWA standard for cast-iron pipe is contained in the *Report of Proceedings of the Tenth Annual Meeting of the American Water Works Association* (1890). In 1902, NEWWA adopted a more detailed standard titled "Standard Specification for Cast Iron Pipe and Special Castings."

The next AWWA standard for pipe and fittings, AWWA 7C.1-1908, was approved May 12, 1908. A second edition, AWWA C100-52T, was approved by AWWA Dec. 31, 1952, and by NEWWA Jan. 23, 1953. The third edition, AWWA C100-54T, was approved by AWWA Oct. 25, 1954, and finally issued as AWWA C100-55, having been advanced from tentative to standard without change June 17, 1955. AWWA C100-55 covered fittings in the size range 4 to 60 in. (102 to 1,500 mm).* The fittings were all bell and spigot (caulked joint) of the so-called long-radius design. The outside diameter (OD) for spigots varied with wall thicknesses, which were designated classes A, B, C, and D. Fittings 4 to 12 in. (102 to 305 mm) were made to class D patterns, having only one OD and pressure rating. Fittings 14 to 24 in. (356 to 610 mm) in size were furnished in classes B and D, and fittings 30 to 60 in. (762 to 1,500 mm) in size were furnished in classes A, B, C, and D. All fittings made in accordance with AWWA 7C.1-1908 and C100-55 had the class identification cast on the fitting.

*Metric conversions given in this standard are direct conversions of US customary units and are not those specified in the International Organization for Standardization (ISO) standards.

ASA* A21.10-1952 (AWWA C110-52) was approved by ASA Sept. 30, 1952, following approval by AWWA May 4, 1951. The standard covered 3- to 12-in. (76- to 305-mm) fittings of the so-called short-body design, which were the subject of extensive research and tests by Committee A21. The rated pressure given by the standard was 250 psi (1,724 kPa) plus water hammer. The standard provided a safety factor of 2.5 plus water hammer based on burst tests. Hydraulic losses were determined and compared with those found with long-radius fittings manufactured in accordance with AWWA Standards. The minimum grade of cast iron in the standard was 25,000 psi (172.4 MPa) tensile strength.

ASA A21.10-1964 (AWWA C110-64) was approved by ASA Jan. 9, 1964. The revision covered 2- to 48-in. (50- to 1,219-mm) fittings. The design of the 14- to 48-in. (356- to 1,219-mm) fittings in the revision was based on an exhaustive series of burst tests. The minimum grade of cast iron (25,000 psi [172.4 MPa] tensile strength) was retained, and higher grades up to 35,000 psi (241.3 MPa) tensile strength were used to secure higher pressure ratings without radically changing the thicknesses. Ductile iron, grade 80-60-03, was also added in the 14- to 48-in. (356- to 1,219-mm) sizes with a rated working pressure of 250 psi (1,724 kPa), having the same wall thicknesses as 150-psi (1,034-kPa)-rated gray-iron fittings. The minimum safety factor based on burst tests of representative fittings of the weakest type was three times the rated working pressure. Tables for flanged fittings and mechanical-joint fittings were added for the first time.

ANSI A21.10-1971 (AWWA C110-71) was approved by ANSI July 14, 1971. Ductile-iron fittings were added in sizes 3 to 12 in. (76 to 305 mm) and were rated for 350 psi (2,413 kPa) working pressure. The grade of ductile iron was changed to 70-50-05 to provide greater toughness. The safety factor against bursting was three times the rated working pressure. If required by the purchaser on special order, fittings were required to withstand a hydrostatic proof test not to exceed one and one half times the rated working pressure without leaks or permanent distortions.

ANSI A21.10a-1972 (AWWA C110a-72) was approved Dec. 17, 1972, as a supplement to ANSI A21.10-1971. The pressure rating for 14- to 24-in. (356- to 610-mm) ductile-iron fittings was increased to 350 psi (2,413 kPa).

ANSI/AWWA C110-77 (ANSI A21.10) was approved by ANSI Apr. 7, 1977. The major change in this revision was the discontinuance of bell-and-spigot fittings (caulked joints) and 2- and 2¼-in. (50- and 56-mm) fittings in the standard. These actions were taken because the use of caulked joints had steadily declined until their use had become a rarity and the 2- and 2¼-in. (50- and 56-mm) sizes were no longer manufactured in the United States. (Bell-and-spigot fittings are still available from some foundries on special order.) With the elimination of 2- and 2¼-in. (50- and 56-mm) sizes, the standard included 3- to 48-in. (76- to 1,219-mm) mechanical-joint and flanged fittings only.

Another change made in the 1977 edition was in bolt lengths for flanged fittings to comply with ANSI/AWWA C115/A21.15-75, Standard for Flanged Cast-Iron and Ductile-Iron Pipe With Threaded Flanges. Appendix A was added to the standard to cover bolts, gaskets, and the installation of flanged fittings. Appendix B was added as a listing of available special fittings that are not a part of the standard. These include

*American Standards Association (ASA) is the former name of the American National Standards Institute.

Copyright by the American Water Works Association
Wed Feb 02 02:11:43 2005

reducing bends, Y-branches, blind flanges, reducing tees, bullhead tees, flared fittings, side-outlet tees and elbows, and wall pipe.

The following note introduced in the 1977 edition cautioned about using mechanical-joint fittings with aged existing cast-iron pipe:

NOTE: Care should be used when connecting mechanical-joint fittings to aged existing cast-iron pipe. The outside diameter of aged pipe should be measured prior to cutting since some of the older pipe was manufactured to a larger diameter than is presently specified in A21 standards. Mechanical-joint sleeves or bell-and-spigot (caulked-joint) sleeves are available to provide transition from existing cast-iron pipe; however, they must be specified on the purchase order. Center to bottom-of-socket dimensions (dimension *A* in Table 3 and dimension *J* in Table 4 of this standard) for A21.10 mechanical-joint fittings are the same as the center to bottom-of-socket dimensions for bell-and-spigot (caulked-joint) fittings specified in the 1971 and previous editions of A21.10. The following standards contain reference dimensions useful in classifying existing cast-iron pipe:

AWWA 7C.1-1908 (AWWA C100-55), Standard Specifications for Cast Iron Pressure Fittings, Table 1.

ASA A21.2-1953 (AWWA C102-53), American Standard for Cast Iron Pit Cast Pipe for Water or Other Liquids, Tables 2.1 and 2.2.

ANSI A21.6-1975 (AWWA C106-75), American National Standard for Cast-Iron Pipe Centrifugally Cast in Metal Molds for Water or Other Liquids, Tables 6.4, 6.5, and 6.6.

ANSI A21.8-1975 (AWWA C108-75), American National Standard for Cast Iron Pipe Centrifugally Cast in Sand-Lined Molds for Water or Other Liquids, Tables 8.4, 8.5, and 8.6.

ANSI/AWWA C151/A21.51-86, American National Standard for Ductile Iron Pipe Centrifugally Cast in Metal Molds or Sand-Lined Molds for Water or Other Liquids, Tables 51.4 and 51.5.

ANSI/AWWA C110/A21.10-82, as approved by ANSI Aug. 24, 1982, introduced no major revisions.

ANSI/AWWA C153/A21.53-84 (First Edition), American National Standard for Ductile-Iron Compact Fittings, 3 In. through 12 In. (76 mm through 305 mm), for Water and Other Liquids, was approved by ANSI Feb. 4, 1985. This standard, developed by Standards Committee A21, Subcommittee 3, Fittings, presents compact fittings designed to use the attendant strength of ductile iron.

ANSI/AWWA C110/A21.10-87 was approved by ANSI Oct. 30, 1987. The major revisions included new sections on rejection of fittings and determination of rejection, and ductile-iron grade 60-42-10 was added. Cast marking of the country where cast was added; Sec. 10-4.3, Joint Accessories, was added; and 14-in. through 48-in. (356-mm through 1,219-mm) solid sleeves made with B-pattern equipment were added.

ANSI/AWWA C110/A21.10-93 was approved by ANSI Aug. 10, 1993. Major revisions in this edition of the standard included the addition of a section on health effects and permeation, allowance for reduced metal-section thicknesses for ductile-iron glands, addition of a precautionary note on the use of flange gaskets thinner than ⅛ in. (3.2 mm) in appendix A, addition of flanged-joint bolt tightening sequence to appendix A, and the addition of a section on ring gaskets in appendix A.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International (NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other

Copyright by the American Water Works Association
Wed Feb 02 02:11:44 2005

members of the original consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA) and the Association of State Drinking Water Administrators (ASDWA) joined later.

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.* Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.
3. Two standards developed under the direction of NSF, ANSI†/NSF‡ 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.
4. Other references, including AWWA standards, *Food Chemicals Codex*, *Water Chemicals Codex*,§ and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

ANSI/AWWA C110/A21.10 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements, including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues.

II.A. *Advisory Information on Product Application.* Unless otherwise provided in the purchaser's specifications, all fittings and accessories shall comply with this standard. Fittings and accessories not complying with this standard shall be replaced by the manufacturer at the agreed point of delivery. The manufacturer shall not be liable for shortages or damaged fittings after the fitting is accepted at the agreed

*Persons in Canada, Mexico, and non-North American countries should contact the appropriate authority having jurisdiction.

†American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

‡NSF International, 3475 Plymouth Rd., Ann Arbor, MI 48106.

point of delivery, except as recorded on the delivery receipt or similar document by the carrier's agent.

III. Use of This Standard.

AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser Options and Alternatives.* This standard includes certain options that, if desired, must be specified in the purchaser's specifications. It is also necessary that such options be included on the purchase order. Also, a number of items must be specified to describe completely the fittings required. The following list summarizes the details and available options, and references the sections of the standard where they are found.

1. Size, joint type, pressure rating (Sec. 1.1 and tables).
2. Joint requirements (Sec. 4.2.1 and 4.2.2).
3. Type of iron (Sec. 4.2.4).
4. End combinations (Sec. 4.2.5).
5. Certification by manufacturer (Sec. 5.1.3).
6. Inspection by purchaser (Sec. 5.2).
7. Elimination of cement-mortar lining (Sec. 4.3.2). Experience has indicated that the petroleum asphaltic inside coating is not complete protection against loss in pipe capacity caused by tuberculation. Cement-mortar linings are recommended for most waters.
8. Special coatings and linings (Sec. 4.3.3).
9. Acceptance tests (Sec. 5.4).
10. Special tests (Sec. 5.6).
11. Special flange bolt-hole orientation (Sec. 4.4.3).

III.B. *Special Service Requirements.* The following special service requirements should be noted:

1. The fittings for which this standard is intended are those normally used for water. Fittings for other services may require special consideration by the purchaser.
2. The method of installation of fittings depends on the type of joint and should be made in accordance with applicable parts of ANSI/AWWA C111/A21.11, Rubber-Gasket Joints for Ductile-Iron and Gray-Iron Pressure Pipe and Fittings; ANSI/AWWA C600, Installation of Ductile-Iron Water Mains and Their Appurtenances; and recommendations of manufacturers regarding their product.
3. Attention is directed to an apparent conflict between this standard and ASME/ANSI B16.1, Cast Iron Pipe Flanges and Flanged Fittings, with regard to pressure ratings for flanged fittings.

In ANSI/AWWA C110/A21.10, flanged joint fittings are rated for 150 or 250 psi (1,034 or 1,724 kPa) working pressure, depending on the material, that is, gray iron or ductile iron; the wall thickness of gray iron; and the size of the fitting. The ratings of these fittings were established on the basis of hydrostatic testing of fittings to bursting and provide for a factor of safety of at least 3.0 at the rated working pressure and at ambient temperature. ANSI/AWWA C110/A21.10 flanges that are adequate for water service of 250 psi (1,724 kPa) working pressure have facing and drilling identical to ASME/ANSI B16.1 class 125 flanges, and match class 125 B16.1 flanges, that for service at –20° to 150°F (–28.9° to 65.6°C) are rated for only 150 to 200 psi (1,034 to 1,724 kPa), depending on the flange size and the class or grade of iron.

Copyright by the American Water Works Association
Wed Feb 02 02:11:45 2005

ASME/ANSI B16.1 covers both separate flanges and flanged fittings of gray iron for service at both ambient and elevated temperatures. The pressure-temperature ratings of these flanges, as set forth in ASME/ANSI B16.1 and stated on the flyleaf of that standard, are not based on burst strength, but have evolved over an extended period of time of satisfactory performance in a wide range of general service conditions. These ratings encompass pressure combined with elevated temperature, stresses imposed by piping, thermal stresses due to temperature variations, and many other conditions causing stress in the flange or fitting.

ASME/ANSI B16.1 also contains the design of a class 250 flange, which is much heavier, has a larger bolt circle, and uses larger-sized bolts than the B16.1 class 125 flange and the flanges covered in ANSI/AWWA C115/A21.15 and this standard. ASME/ANSI B16.1 class 250 flanges will not connect to the B16.1 class 125 flange, the ANSI/AWWA C115/A21.15 flange, or the ANSI/AWWA C110/A21.10 flange.

4. Although this standard does not detail the orientation of bolt holes in the flanges of the mechanical joint, it is at times convenient or necessary to have the bolt holes specially oriented. The normal but not universal practice is to have the bolt holes straddle the vertical centerline of the fittings, valves, and hydrants. (The vertical centerline of a fitting is determined when the fitting is in the position to change the direction of fluid flowing in a horizontal plane. With standard base bends and standard base tees, the vertical centerline is determined when the fitting is in a position to change the fluid flowing in a vertical plane.) If special orientation is known to be necessary, it should be stated on the purchase order.

III.C. *Modification to Standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. The major revisions made to this standard in this edition are as follows:

1. The format has been changed to AWWA standard style.
2. Section I.A, Background, was revised to recognize the withdrawal of the American Gas Association as cosecretariat of the A21 Committee.
3. The acceptance clause (Sec. I.C) has been revised to approved wording.
4. The advisory information paragraph (Sec. II.A) was revised and moved from the body of the standard into the foreword.
5. The scope of the standard has been limited to water service and all references to gas and other liquids have been eliminated.
6. The scope was amended to recognize 350-psi (2,413-kPa) ratings for 12-in. (305-mm) and smaller flanged ductile-iron fittings when used with special gaskets.
7. Cement-mortar linings (Sec. 4.3.2) was revised to reflect the optional status of seal coat in the latest revision of ANSI/AWWA C104/A21.4.
8. Special coatings and linings (Sec. 4.3.3) was revised to include asphaltic material as a special lining.
9. Table 1 was revised in accordance with the 1995 revision of ANSI/AWWA C111/A21.11. Revisions include plus tolerances on the K_1, K_2, and L dimensions; longer bolt lengths for the 42- and 48-in. (1,067- and 1,219-mm) sizes; and the footnote on ductile-iron glands.
10. Tables 16 through 19 on flanged fittings were revised to show the use of ductile iron for 3- to 12-in. (76- to 305-mm) flanged fittings with the same dimensions as gray-iron fittings. Explanatory footnotes were also added.
11. The gaskets section of appendix A was revised to describe the rubber material as being synthetic.

ANSI/AWWA C110/A21.10-98
(Revision of ANSI/AWWA C110/A21.10-93)

AMERICAN NATIONAL STANDARD FOR

DUCTILE-IRON AND GRAY-IRON FITTINGS, 3 IN. THROUGH 48 IN. (76 mm THROUGH 1,219 mm), FOR WATER

SECTION 1: GENERAL

Sec. 1.1 Scope

This standard covers 3- to 48-in. (76- to 1,219-mm) gray-iron and/or ductile-iron fittings to be used with ductile-iron pipe for water. Requirements for fittings with mechanical joints and flanged joints are listed in Tables 1 through 20 at the end of this standard. This standard may also be used for fittings with push-on joints or such other joints as may be agreed on at the time of purchase.

For the 3- to 24-in. (76- to 610-mm) size range, ductile-iron mechanical-joint fittings and ductile-iron push-on-joint fittings are rated for 350 psi (2,413 kPa) working pressure. Ductile-iron flange-joint fittings are rated for 250-psi (1,724-kPa) working pressure; however, 12-in. (305-mm) and smaller sizes may be rated for 350 psi (2,413 kPa) with the use of special gaskets. Gray-iron fittings having all types of joints covered by this standard are rated for 150- or 250-psi (1,034- or 1,724-kPa) working pressures, as shown in the tables.

For the 30- to 48-in. (762- to 1,219-mm) size range, fittings with all types of joints covered by this standard are shown in the tables with rated working pressures of 150 or 250 psi (1,034 or 1,724 kPa), depending on the type of iron as shown in the tables.

Copyright by the American Water Works Association
Wed Feb 02 02:11:46 2005

Sec. 1.2 Purpose

The main purpose of this standard is to provide the minimum requirements for ductile-iron and gray-iron fittings, 3 in. through 48 in. (76 mm through 1,219 mm), for water.

Sec. 1.3 Application

This standard can be referenced in specifications for ductile-iron and gray-iron fittings, 3 in. through 48 in. (76 mm through 1,219 mm), for water. The stipulations of this standard apply when this document has been referenced and then only to ductile-iron and gray-iron fittings, 3 in. through 48 in. (76 mm through 1,219 mm), for water.

SECTION 2: DEFINITIONS

The following definitions shall apply in this standard:

1. *Ductile iron:* A cast ferrous material in which a major part of the carbon content occurs as free graphite in a substantially nodular or spheroidal form.
2. *Flange joint:* The flanged and bolted joint as detailed in Figure 14 and Table 14.
3. *Gray iron:* The cast ferrous material in which a major part of the carbon content occurs as free graphite in the form of flakes interspersed throughout the metal.
4. *Manufacturer:* The party that manufactures, fabricates, or produces materials or products.
5. *Mechanical joint:* The gasketed and bolted joint as detailed in the latest revision of ANSI/AWWA C111/A21.11.
6. *Purchaser:* The person, company, or organization that purchases any materials or work to be performed.
7. *Push-on joint:* The single rubber-gasket joint as set forth in the latest revision of ANSI/AWWA C111/A21.11.

SECTION 3: REFERENCES

This standard references the following documents. In their latest editions, they form a part of this standard to the extent specified within the standard. In any case of conflict, the requirements of this standard shall prevail.

ANSI/AWWA C600—Standard for Installation of Ductile-Iron Water Mains and Their Appurtenances.

SECTION 4: REQUIREMENTS

Sec. 4.1 Permeation

The selection of materials is critical for water service and distribution piping in locations where there is likelihood the pipe will be exposed to significant concentrations of pollutants composed of low molecular weight petroleum products or organic solvents or their vapors. Research has documented that pipe materials such as polyethylene, polybutylene, polyvinyl chloride, and asbestos cement, and elastomers, such as used in jointing gaskets and packing glands, may be subject to permeation by lower molecular weight organic solvents or petroleum products. If a water pipe must pass through such a contaminated area or an area subject to contamination, consult with the manufacturer regarding permeation of pipe walls, jointing materials, and so forth, *before* selecting materials for use in that area.

Sec. 4.2 General Requirements

4.2.1 *Mechanical joint and flange joint.* Fittings with mechanical joints and flange joints shall conform to the dimensions and weights shown in the tables in this standard unless otherwise agreed on at the time of purchase. The mechanical joint shall also conform to ANSI/AWWA C111/A21.11. Either ductile-iron or gray-iron glands may be used unless otherwise specified by the purchaser.

Split glands and glands in segments and other variations shall be allowed, provided they meet the performance requirements of ANSI/AWWA C111/A21.11.

4.2.2 *Push-on joint.* Fittings with push-on joints shall have weights and dimensions of the bell, socket, and plain end in accordance with the manufacturer's standard design. The manufacturer shall furnish drawings of the joint and gasket if requested by the purchaser. Performance requirements and special requirements for push-on joints shall conform to the requirements for the push-on joint in ANSI/AWWA C111/A21.11.

4.2.3 *Joint accessories.* Unless otherwise specified by the purchaser, gaskets, glands, bolts, and nuts shall be furnished with mechanical joints; and gaskets and lubricant shall be furnished with push-on joints; all in sufficient quantity for assembly of each joint.

4.2.4 *Type of iron.* Fittings shall be cast from gray iron or ductile iron and have pressure ratings as shown in the tables. When both materials are shown in the tables, either may be furnished at the manufacturer's option unless otherwise

Copyright by the American Water Works Association
Wed Feb 02 02:11:47 2005

specified by the purchaser. All fittings shall be capable of withstanding, without bursting, hydrostatic tests of three times the rated water working pressure.

4.2.5 *Other joint designs or dimensions.* Standard fittings shall be furnished with the end combinations shown in the tables. When fittings of other designs or dimensions are purchased under this standard, the purchaser must specify the fitting design. Plain ends of mechanical-joint fittings may be furnished with bevels for assembly with push-on joint bells.

NOTE: Bell fittings without plain ends are most readily available.

Sec. 4.3 Coatings and Linings

4.3.1 *Outside coating.* The outside coating shall be a petroleum asphaltic coating approximately 1 mil (25 μm) thick. The coating shall be applied to the outside of all fittings unless otherwise specified by the purchaser. The finished coating shall be continuous, smooth, neither brittle when cold nor sticky when exposed to the sun, and strongly adherent to the fitting.

4.3.2 *Cement-mortar linings.* The lining for use under normal conditions shall be a cement-mortar lining in accordance with the latest revision of ANSI/AWWA C104/A21.4, unless otherwise specified.* Cement-mortar linings are not normally furnished in sleeves, plugs, or caps.

4.3.3 *Special coatings and linings.* For special conditions, other types of coatings and linings may be available. Special coatings and linings shall be specified by the purchaser. One special lining for fittings that are not cement-mortar lined is an asphaltic material as thick as practicable, at least 1 mil (25 μm), that conforms to all appropriate requirements for seal coat, as described in the latest revision of ANSI/AWWA C104/A21.4.

Sec. 4.4 Special Requirements for Flanged Fittings

4.4.1 *Flanges.* Flanges shall conform to the dimensions shown in Table 14, which are adequate for the pressure ratings given in Sec. 4.2.2 of ANSI/AWWA C111/A21.11.

NOTE: The bolt circle and bolt holes of these flanges match those of ASME/ANSI B16.1 and can be joined with these class 125 flanges. Flanges of ANSI/AWWA C110/A21.10 fittings cannot be joined with class 250 B16.1 flanges.

4.4.2 *Facing.* Flanges shall be flat-faced without projection or raised-face and shall be furnished smooth or with shallow serrations. Flanges may be back-faced or spot-faced for compliance with the flange thickness tolerance set forth in this standard. Bearing surfaces for bolting shall be parallel to the flange face within 3°.

4.4.3 *Bolt holes.* Bolt holes shall be in accordance with the dimensions shown in Table 14. Bolt holes shall be equally spaced and shall straddle the centerlines of the flange as shown in Figure 14.

4.4.3.1. Misalignment of corresponding bolt holes of two opposing flanges shall not exceed 0.12 in. (3.0 mm).

4.4.3.2. If bolt-hole orientation other than provided for in this standard is required by the purchaser, the special orientation shall be specified in the purchaser's specification.

*Experience indicates that the petroleum asphaltic inside coating is not complete protection against loss in pipe capacity caused by tuberculation. Cement-mortar linings are recommended for most waters.

Copyright by the American Water Works Association
Wed Feb 02 02:11:47 2005

4.4.4 *Laying-length dimensions.* Face-to-face dimensions shall conform to a tolerance of ±0.06 in. (±1.5 mm) for sizes 3 to 10 in. (76 to 254 mm) and ±0.12 in. (±3.0 mm) for sizes 12 to 48 in. (305 to 1,219 mm). Center-to-face tolerances shall be one half those of face-to-face tolerances. The largest opening shall govern the tolerance for all openings.

SECTION 5: VERIFICATION

Sec. 5.1 Inspection and Certification by Manufacturer

5.1.1 *Quality control and inspection practice.* The manufacturer shall establish the necessary quality control and inspection practice to ensure compliance with this standard. All fittings shall be clean and sound without defects that could impair their service.

5.1.2 *Repairs of defects.* Repairing defects by welding or other methods shall not be allowed if such repairs could adversely affect the serviceability of the fitting or its capability to meet the strength requirements of this standard.

5.1.3 *Certification by manufacturer.* If required by the purchaser, the manufacturer shall furnish a sworn statement that the inspection and all the specified tests have been made and the results thereof comply with the requirements of this standard.

5.1.4 *Manufacturer's records.* The results of the specified tests (Sec. 5.4, 5.5, 5.6, and 5.9 if applicable) shall be recorded and retained for one year and shall be available to the purchaser at the manufacturer's plant.

Sec. 5.2 Inspection by Purchaser

5.2.1 *Purchaser's obligations.* If the purchaser desires to inspect fittings at the manufacturer's plant, it shall be stated in the purchaser's specifications and the conditions described under which the inspection shall be made (such as time and extent of the inspection).

5.2.2 *Manufacturer's obligations.* The purchaser's representative shall have free access to those areas of the manufacturer's plant as are necessary to determine compliance with this standard. The manufacturer shall make available for the use by the purchaser's representative such gauges as are necessary for inspection. The manufacturer shall provide the purchaser's representative with assistance as necessary for the handling of fittings.

Sec. 5.3 Tolerances or Permitted Variations

5.3.1 *Dimensions.* Fittings shall be measured with suitable gauges at sufficiently frequent intervals to ensure that the dimensions comply with the requirements of this standard. The smallest inside diameter (ID) of the sockets and the outside diameter (OD) of the plain ends shall be tested with circular gauges. Other socket dimensions shall be measured as appropriate.

Copyright by the American Water Works Association
Wed Feb 02 02:11:48 2005

5.3.2 *Thickness.* Minus tolerances for metal thicknesses, except those shown in Tables 1 and 2, shall not exceed the following:

Fitting Size*	Minus Tolerance	
in.	*in.*	*(mm)*
3–6	0.10	(2.5)
8–20	0.12	(3.0)
24–48	0.15	(3.8)

*Metric conversion for dimension: in. × 25.4 = mm.

An additional tolerance shall be permitted over areas not exceeding 8 in. (200 mm) in any direction as follows: for 3- to 12-in. (76- to 305-mm) fittings, 0.02 in. (0.5 mm); for 14- to 48-in. (356- to 1,219-mm) fittings, 0.03 in. (0.8 mm).

5.3.3 *Weight.* The weight of any fitting shall not be less than the nominal tabulated weight by more than 10 percent for fittings 12 in. (305 mm) or smaller in diameter or by more than 8 percent for fittings larger than 12 in. (305 mm) in diameter. The nominal tabulated weight is the weight of the fitting before the application of any lining or coating other than the standard coatings.

Sec. 5.4 Acceptance Tests

5.4.1 *Physical test—gray-iron fittings.* The standard acceptance test for the physical characteristics of gray-iron fittings shall be one of the following:

1. Transverse test conducted in accordance with ASTM A438.
2. Tensile test conducted in accordance with ASTM A48.
3. Transverse or tensile tests conducted on coupons obtained from a part of the castings' runner-bar system or the casting. The diameter of the runner bar or the thickness of the casting where the test coupon or bar is selected must be similar to that required of ASTM A438 or A48 test bars.

5.4.1.1 Choice of test. Unless specified by the purchaser, selection of the test bar coupon and test method (either the transverse test or tensile test, as the acceptance test) shall be at the option of the manufacturer. The acceptance values for tensile and transverse tests shall be as shown in the following table.

Iron Strength		Fitting Size	Bar Diam.		Span†		Min. Breaking Load		Min. Tensile Strength‡	
psi (1,000s)	*(MPa)*	*in.**	*in.*	*(mm)*	*in.*	*(mm)*	*lb*	*(kg)*	*psi (1,000s)*	*(MPa)*
25	(172)	3–14	1.20	(30.5)	18	(457)	2,000	(907)	25	(172)
30	(207)	14–24	1.20	(30.5)	18	(457)	2,200	(998)	30	(207)
30	(207)	20–48	2.00	(50.8)	24	(610)	7,600	(3,447)	30	(207)
35	(241)	16–24	1.20	(30.5)	18	(457)	2,400	(1,089)	35	(241)
35	(241)	20–36	2.00	(50.8)	24	(610)	8,300	(3,765)	35	(241)

*Metric conversion for dimension: in. × 25.4 = mm.

†ASTM A438.

‡ASTM A48.

Copyright by the American Water Works Association
Wed Feb 02 02:11:48 2005

For 20-in. (508-mm) and 24-in. (610-mm) fittings with a body thickness greater than 1 in. (25.4 mm), a 2-in. (50.8-mm) test bar shall be used.

5.4.2 *Physical test—ductile-iron fittings.* The standard acceptance test for the physical characteristics of ductile-iron fittings shall be a tensile test on coupons cast from the same iron as the fittings.

Except as otherwise provided herein, coupons shall be cast and the test made in accordance with ASTM A536. The test coupon shall be obtained, at the manufacturer's option, from one of the following: (1) the ASTM A536 keel block, modified keel block, or Y-block separately cast coupon; (2) the castings' runner-bar system, provided that the diameter of the runner bar at the location the coupon is selected is similar to the respective ASTM A536 coupon; or (3) the casting.

5.4.2.1 Acceptance value. The standard grade of iron shall be 70-50-05, with acceptance values as follows: minimum tensile strength, 70,000 psi (483 MPa); minimum yield strength, 50,000 psi (345 MPa); minimum elongation, 5 percent.

Another permissible acceptance value shall be the 60-42-10 grade of iron, with acceptance values as follows: minimum tensile strength, 60,000 psi (414 MPa); minimum yield strength, 42,000 psi (290 MPa); and minimum elongation, 10 percent; provided the manufacturer of fittings produced from this grade can furnish records to demonstrate that such fittings meet the performance test requirements of this standard.

5.4.3 *Sampling.* At least one sample shall be taken during each period of approximately 3 h, while the melting unit is operated continuously.

Sec. 5.5 Chemical Limitations

5.5.1 *Gray-iron fittings.* Analyses of the iron in gray-iron fittings shall be made at sufficiently frequent intervals to ensure compliance with the following limits: phosphorus, 0.90 percent maximum; sulfur, 0.15 percent maximum.

Control of the other chemical constituents shall be maintained to meet the physical property requirements of this standard. Samples for chemical analyses shall be representative and shall be obtained from either acceptance-test specimens or specimens cast for this purpose.

5.5.2 *Ductile-iron fittings.* Analyses of the iron shall be made at sufficiently frequent intervals to ensure compliance with the following limit: phosphorus, 0.08 percent maximum. Control of other chemical constituents shall be maintained to meet the physical property requirements of this standard.

Samples for chemical analyses shall be representative and shall be obtained from either an acceptance-test specimen or specimens cast for this purpose.

Sec. 5.6 Additional Tests Required by the Purchaser

If tests other than those provided in this standard are required by the purchaser, such tests shall be specified by the purchaser. Although it is not customary to make hydrostatic proof tests of fittings at the foundry, such tests may be made on special order at additional cost. If proof tests at the foundry are required by the purchaser for an order of fittings, the fittings shall withstand, without leaks or permanent distortion, hydrostatic test pressures not to exceed one and one half times the rated water working pressures.

Copyright by the American Water Works Association
Wed Feb 02 02:11:49 2005

Sec. 5.7 Defective Specimens and Retests

When any physical test specimen shows defective machining or lack of continuity of metal, it shall be discarded and replaced by another specimen cast in the same sampling period as the specimen that failed.

Sec. 5.8 Rejection of Fittings

If the test results of any sound specimen fail to meet the applicable requirements of Sec. 5.4, or the chemical analyses do not conform to the limitations of Sec. 5.5 where applicable, the fittings represented by these tests and/or analyses shall be rejected, except as provided in Sec. 5.9.

Sec. 5.9 Determining Rejection

The manufacturer may limit the amount of rejection by making additional acceptance tests until the rejected lot is bracketed, in order of manufacture, by an acceptable test at each end of the interval in question.

SECTION 6: DELIVERY

Sec. 6.1 Marking

Fittings shall have distinctly cast on them the pressure rating, nominal diameters of openings, manufacturer's identification, country where cast, and the number of degrees or fraction of the circle on all bends. Ductile-iron fittings shall have the letters "DI" or "Ductile" cast on them. Cast letters and figures shall be on the outside body of the fitting and shall have dimensions no smaller than the following:

Fitting Size*	Height of Letters		Relief	
in.	*in.*	*(mm)*	*in.*	*(mm)*
Less than 8	As large as practical		As large as practical	
8–10	¾	(19)	3/32	(2.5)
12–48	1¼	(32)	3/32	(2.5)

*Metric conversion for dimension: in. × 25.4 = mm.

Sec. 6.2 Packing and Shipping

This standard has no applicable information for this section.

Sec. 6.3 Affidavit of Compliance

This standard has no applicable information for this section.

NOTES:

1. The nominal thickness *S* shall not be less than the nominal thickness of the fitting of which it is a part.
2. The diameter of cored holes may be tapered an additional 0.06 in. (1.5 mm).
3. Dimension *A* in Table 1 is the outside diameter of the plain end of the fitting.
4. In the event of an ovalness to the outside diameter of the plain end, the mean diameter measured by a circumferential tape shall not be less than the minimum diameter shown in Table 1. The minor axis shall not be less than the foregoing minimum diameter plus an additional minus tolerance of 0.04 in. (1.0 mm) for sizes 8–12 in. (203–305 mm), 0.07 in. (1.8 mm) for sizes 14–24 in. (356–610 mm), and 0.10 in. (2.5 mm) for sizes 30–48 in. (762–1,219 mm).
5. K_1 and K_2 are the dimensions across the centerline of the bolt holes. The gray-iron gland and bell flange may be round or polygon in shape for all sizes or square for 3-in. (76-mm) and 4-in. (100-mm) sizes. Ductile-iron glands may be other shapes as long as the gland meets the performance requirements specified in Sec. 4.5, ANSI/AWWA C111/A21.11.
6. Gland thickness *M* for sizes 14–48 in. (356–1,219 mm) may be tapered as shown, at the option of the manufacturer.
7. For ductile-iron glands, the gland thickness *M* listed above is not applicable. Designs incorporating reduced metal-section thicknesses are permitted provided tests with these glands meet the performance requirements of Sec. 4.5, ANSI/AWWA C111/A21.11. Conformance with *N* dimensions shown in Table 1 is required at the bolt holes for all glands, gray iron or ductile iron, to ensure interchangeability of joint parts.

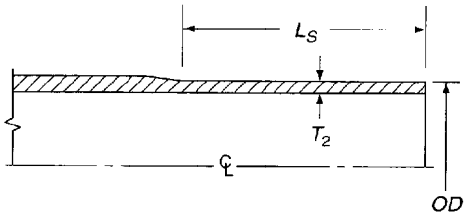
*Dimension details of bell are shown in Figure 1.

†Bolt lengths shown for the 8-in. through 16-in. sizes are ½ in. longer than ANSI/AWWA C153/A21.53-88 bolts for use with ANSI/AWWA C153/A21.53 fittings for these sizes. These longer ANSI/AWWA C111/A21.11 bolts, shown in the table above, may also be furnished with compact fittings in sizes 8–16 in. with the bolt thread length as shown in Figure 3 and Figure 4 of ANSI/AWWA C111/A21.11.

‡For ductile-iron glands, the flange thickness *M* listed above is not applicable. Designs incorporating reduced metal-section thicknesses are permitted provided tests with these glands meet the performance requirements of Sec. 4.5 of ANSI/AWWA C111/A21.11. Conformance with *N* dimensions shown in Table 1 is required for all glands, gray iron or ductile iron, to ensure interchangeability of joint parts.

NOTE: Metric conversions: Dimension: in. × 25.4 = mm.

Copyright by the American Water Works Association
Wed Feb 02 02:11:50 2005



NOTES:

1. All sizes of fittings with plain ends have 8 in. (203 mm) of added laying length as compared with the laying length of standard all-bell fittings.
2. In Figure 2, dimension L_S is the minimum length of the plain end that must be gauged to ensure that the outside diameter is within the dimensions and tolerances specified in Table 2.
3. Metric conversions:
   Iron strength: psi (1,000s) × 6.89 = MPa;
   Pressure rating: psi × 0.00689 = MPa;
   Dimension: in. × 25.4 = mm;
   Weight: lb × 0.4536 = kg

Metric conversions: Iron strength: psi (1,000s) × 6.89 = MPa; Pressure rating: psi × 0.00689 = MPa; Dimension: in. × 25.4 = mm; Weight: lb × 0.4536 = kg.

*Dimension details of mechanical-joint bells are shown in Table 1; dimension details of plain ends are shown in Table 2.

†Weight does not include accessory weights.

‡Ductile iron.

Metric conversions: Iron strength: psi (1,000s) × 6.89 = MPa; Pressure rating: psi × 0.00689 = MPa; Dimension: in. × 25.4 = mm; Weight: lb × 0.4536 = kg.

*Fittings made of ductile iron in the 12-in. and smaller sizes may be rated at 350 psi with the use of a special gasket.

†Dimension details of flanges are in Table 14.

‡3–12-in. sizes may be gray iron (class 25) or ductile iron.

Metric conversions: Iron strength: psi (1,000s) × 6.89 = MPa; Pressure rating: psi × 0.00689 = MPa; Dimension: in. × 25.4 = mm; Weight: lb × 0.4536 = kg.

*Fittings made of ductile iron in the 12-in. and smaller sizes may be rated at 350 psi with the use of a special gasket.

†Dimension details of flanges are in Table 14.

APPENDIX A

Flanged Fittings—Bolts, Gaskets, and Installation

This appendix is for information only and is not a part of ANSI/AWWA C110/A21.10.

The bolts and gaskets to be used with the flanged fittings are to be selected by the purchaser with due consideration for the particular pressure service and installation requirements.

SECTION A.1: BOLTS AND NUTS

Size, length, and number of bolts are shown in Table 14 of ANSI*/AWWA C110/A21.10. Bolts conform to ASME†/ANSI B18.2.1, Square and Hex Bolts and Screws Inch Series Including Hex Cap Screws and Lag Screws, and nuts conform to ASME/ANSI B18.2.2, Square and Hex Nuts. Bolts smaller than ¾ in. (19 mm) have either standard square or heavy hex heads and heavy hex nuts. Bolts ¾ in. (19 mm) and larger have either square or hex heads and either hex or heavy hex nuts. Bolts and nuts are threaded in accordance with ASME/ANSI B1.1, Unified Inch Screw Threads (UN and UNR Thread Form) class 2A external and class 2B internal. Bolts and nuts are low-carbon steel and conform to the chemical and mechanical requirements of ASTM‡ A307, Standard Specification for Carbon Steel Bolts and Studs, 60,000 PSI Tensile Strength, grade B. The carbon–steel bolts should be used where gray-iron flanges are installed with flat ring gaskets that extend only to the bolts. Higher-strength bolts may properly be used where gray-iron flanges are installed with full-face gaskets. Higher-strength bolts may be used where ductile flanges are installed with either ring or full-face gaskets.

SECTION A.2: GASKETS

Gaskets are synthetic rubber, either ring or full face, and are ⅛ in. (3.2 mm) thick, unless otherwise specified by the purchaser, conforming to the dimensions shown in Table A.1, Flange gasket details. NOTE: When considering the use of gaskets thinner than ⅛ in. (3.2 mm) and/or gaskets of material other than synthetic rubber, the purchaser should contact the fitting manufacturer. Also available for most sizes are specially designed gaskets, either ring or full face, using one or more annular rings molded into the gasket to improve the gasket performance.

SECTION A.3: INSTALLATION

The design, assembly, and installation of the flanged piping system are the responsibility of the purchaser. The following suggestions are for general guidance:

a. The underground use of flanged joints is generally not desirable because of the rigidity of the joint.

b. Flange faces should bear uniformly on the gasket and the bolts tightened in progressive crisscross order, such as by tightening the bottom bolt first; then, the top bolt; next, the bolts at either side; and, finally, the remaining bolts. This process should be repeated until all bolts are sufficiently tight to prevent leakage at the joint.

c. Users of flanged fittings should be careful to prevent bending or torsional strains from being applied to flanges, flanged fittings, or flanged appurtenances. Piping systems must be designed so that piping connected to flanges or flanged fittings is properly anchored, supported, or restrained to prevent breakage of fittings and flanges.

d. Ring gaskets are recommended for 14-in. (350-mm) and larger sizes if flat gaskets are used.

Table A.1 Flange gasket details

	Dimensions—*in.*						
	Ring		Full Face				
Nom. Size *in.*	Nom. *ID*	*OD*	Nom. *ID*	*OD*	*BC*	Bolt Hole Diam.	No. of Holes

Dual (combination)-purpose modified MJ sleeve

NOTE: The joining of cast-iron pipe of the same nominal size but with different outside diameters can be accomplished with a special dual- or combination-purpose, modified mechanical-joint sleeve. This special sleeve, available from some manufacturers in 4–12-in. (102- to 305-mm) nominal size, is designed for use with pipe having either *A* or *CD* outside diameters. The sleeve employs an identical gasket at each end, which can adapt itself to either *A* or *CD* diameter pipe. These gaskets and the glands used with this sleeve are not the same as and are not interchangeable with gaskets and glands used with ANSI/AWWA C111/A21.11 standardized mechanical joints.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

All rights reserved. No part of this publication may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopy, recording, or any information or retrieval system, except in the form of brief excerpts or quotations for review purposes, without the written permission of the publisher.

Foreword

This foreword is for information only and is not a part of AWWA C105/A21.5

I. Introduction.

I.A. *Background.* In 1926, the American Standards Association (ASA) (now American National Standards Institute [ANSI]) Committee A21, Cast-Iron Pipe and Fittings, was organized under the sponsorship of the American Gas Association (AGA), the American Society for Testing and Materials (ASTM), American Water Works Association (AWWA), and the New England Water Works Association (NEWWA). The current sponsor is AWWA, and the present scope of Committee A21 is to develop standards and manuals for ductile-iron pressure pipe for water supply service and ductile-iron and gray-iron fittings for use with this pipe. These standards and manuals include design, dimensions, materials, coatings, linings, joints, accessories, and methods of inspection and testing.

In 1958, Committee A21 was reorganized. Standards were divided into groups focusing on the topics listed above, and subcommittees were established to study each group in accordance with the review and revision policy of ASA. In 1984, the committee became AWWA Standards Committee A21 on Ductile-Iron Pipe and Fittings.

The present scope of A21 Subcommittee 4, Coatings and Linings, is to review interior and exterior corrosion of ductile-iron pipe and fittings and to draft standards for the interior and exterior protection of ductile-iron pipe and fittings. Accordingly, Subcommittee 4 is responsible for the development of

1. Standards on polyethylene encasement materials and their installation to provide corrosion protection, when required, for ductile-iron pipe and fittings.
2. Procedures for the investigation of soil to determine when polyethylene protection is indicated.

I.A.1 History of polyethylene encasement. Loose polyethylene encasement was first used experimentally in the United States in 1951 for protection of gray-iron pipe in corrosive environments. The first field installation of polyethylene wrap on gray-iron pipe in an operating water system was in 1958. The installation consisted of approximately 600 ft (180 m) of 12-in. (305-mm) pipe installed in a waste-dump fill area. Since 1958, polyethylene encasement has been used extensively in installations in severely corrosive soils throughout the United States on pipe ranging in size from 3 in. to 64 in. (76 mm to 1,600 mm) in diameter. Polyethylene encasement has been used as a soil-corrosion preventative in a number of other countries as well. An International Standard for Polyethylene Sleeving (ISO-8180)* has been adopted since the procedure was developed in the United States.

I.A.2 Research. The Cast Iron Pipe Research Association (CIPRA)† (now known as the Ductile Iron Pipe Research Association [DIPRA]) has researched several severely corrosive test sites. The tests indicate that polyethylene encasement provides a high degree of protection resulting in minimal and generally insignificant exterior surface corrosion of ductile-iron and gray-iron pipe protected in this manner.

---

*International Organization for Standardization, Geneva, Switzerland.

†CIPRA became the Ductile Iron Pipe Research Association (DIPRA) in 1979.

Wed Feb 02 02:10:20 2005

Investigations of many field installations in which loose polyethylene encasement has been used as protection for ductile-iron and gray-iron pipe against soil corrosion confirm DIPRA's findings. These field installations also indicate that the dielectric capability of polyethylene provides shielding for ductile-iron and gray-iron pipe from stray direct current at most levels encountered in the field.

I.B. *History.* The first edition of this standard was published in 1972 as American National Standard for Polyethylene Encasement for Gray and Ductile Cast-Iron Piping for Water and Other Liquids.

In 1976, Subcommittee 4 reviewed the 1972 edition and submitted a recommendation to Committee A21 that the standard be reaffirmed without change, except for updating the foreword.

In the 1982 revision, ANSI/AWWA C105/A21.5-82, references to gray cast-iron pipe were deleted from the title and throughout the standard because gray cast-iron pipe was no longer produced in the United States. Also, metric conversions of all dimensions were added to the standard.

The 1986 edition of the standard defined the thickness requirement for polyethylene film; provided new figures showing installation methods; and extended the length of connecting piping to be wrapped from 2 ft (0.6 m) to 3 ft (0.9 m). Additionally, a requirement for wrapping service lines of dissimilar metals for a distance of 3 ft (0.9 m) from the ductile iron pipe was also incorporated.

In the 1993 revision of the standard, Section 4.1, Materials, was expanded to include 4-mil, high-density, cross-laminated ("HDCL") polyethylene and Class B (colors) material was added to allow the purchase of colored polyethylene. Additionally, Table 1 was modified to reflect reduced tube widths comparable with push-on joint pipe and fittings, and the size range was expanded to include 60- and 64-in. (1,500- and 1,600-mm) pipe. A recommendation that circumferential wraps of tape be placed at 2-ft (0.6-m) intervals along the barrel of the pipe for installation below the water table or in areas subject to tidal actions was added to Section 4.3.1, and Section 4.3.6 was revised to indicate the preferred method of making direct service taps on polyethylene encased pipe. An illustration of this procedure was added.

II. Special Issues.

II.A. *Useful life of polyethylene.* Tests of polyethylene used to protect ductile-iron and gray-iron pipe have shown that, after 40 years of exposure to severely corrosive soils, strength loss and elongation reduction are insignificant. US Bureau of Reclamation (BUREC)* studies of polyethylene film used underground illustrate that tensile strength was nearly constant and that elongation was only slightly affected during a seven-year test period. BUREC's accelerated soil-burial testing (acceleration estimated to be 5 to 10 times that of field conditions) shows polyethylene to be highly resistant to bacteriological deterioration.

II.B. *Type of material.* The materials described in this standard are a linear low-density polyethylene film and a high-density cross-laminated film. A low-density film was used in the initial research and testing of polyethylene encasement to protect ductile-iron and gray-iron pipe from corrosion. The current materials provide the same degree of protection as the low-density film and are stronger and more damage resistant. Other types of polymeric material are also available that may provide equally suitable protection.

*Laboratory and Field Investigations of Plastic Films. US Department of the Interior, Bureau of Reclamation, Rept. No. ChE-82 (Sept. 1968).

Copyright by the American Water Works Association
Wed Feb 02 02:10:21 2005

II.C. *Exposure to sunlight.* Prolonged exposure to sunlight will eventually deteriorate polyethylene film. Although the film is required to contain not less than 2 percent carbon black or 2 percent of a hindered-amine ultraviolet inhibitor, exposure of wrapped pipe should be kept to a minimum.

II.D. *Copper service connections.* The direct connection of copper services to ductile- and gray-iron pipelines has historically been a common practice in the waterworks industry. To minimize the possibility of bi-metallic corrosion, service lines of dissimilar metals and the attendant corporation stop should be wrapped with polyethylene or a suitable dielectric tape for a minimum clear distance of 3 ft (0.9 m) from the main (Sec. 4.4.7).

In addition, the grounding of household electrical services to the copper water service line may also result in stray current corrosion of the copper service or the ductile-iron or gray-iron main. AWWA policy opposes the grounding of electrical systems to pipe systems conveying drinking water to a customer's premises. AWWA further states that interior piping systems may be connected to an electrical service neutral and to a separate grounding electrode, provided these systems are electrically insulated from the water utility's pipe system. To minimize the possibility of stray current corrosion on the ductile-iron or gray-iron main, electrical insulating couplings should be installed at the water main.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser options and alternatives.* This standard includes certain options that, if desired, must be specified. These options are

1. Color of polyethylene material (Sec. 4.1.3).
2. Installation method—A, B, or C (Sec. 4.3)—if there is a preference.
3. Type of polyethylene material (Sec. 4.1.1 and 4.1.2).

III.B. *Modification to standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. The major revisions in this edition of the standard are as follows:

1. The format has been changed to AWWA standard style.
2. Section II.D, Copper Service Connections, was added to the Foreward of the standard.
3. Definitions of parties and types of polyethylene film were added to Sec. 3.
4. Changes to Sec. 4.1., Materials, include:
   a. Deletion of low-density polyethylene film.
   b. Addition of linear low-density polyethylene film and appropriate material requirements and physical properties.
   c. Increasing the tensile strength requirement for the high-density, cross-laminated polyethylene film.
   d. Addition of impact and tear resistance requirements for both polyethylene materials.
   e. Deletion of the minus tolerance on film thickness for both materials.
   f. Addition of an ultraviolet inhibitor, any natural or colored film except black film containing carbon block.
5. Sec. 4.3, Marking, was added to facilitate traceability and to help ensure compliance with the standard.

Copyright by the American Water Works Association
Wed Feb 02 02:10:21 2005

6. In Sec. 4.4.2.2, Method B, an alternate method of using a 3-ft sheet of polyethylene rather than a 3-ft length of polyethylene tube for joint makeup was added.

7. Sec. 5.1, Inspection and Certification by Manufacturer, was also added to help ensure compliance with this standard.

8. In appendix A, a new paragraph on stray current corrosion and a new section on uniquely severe environments were added. Additionally, the resistivity ranges in Table A.1, Soil Test Evaluation, were increased to make the procedure more conservative.

V. Comments. If you have any comments or questions about this standard, please call the AWWA Volunteer and Technical Support Group, (303) 794-7711 Ext. 6283, FAX (303) 795-7603, or write to the group at 6666 W. Quincy Ave., Denver, CO 80235.

ANSI/AWWA C105/A21.5-99
(Revision of ANSI/AWWA C105/A21.5-93)

AMERICAN NATIONAL STANDARD FOR

POLYETHYLENE ENCASEMENT FOR DUCTILE-IRON PIPE SYSTEMS

SECTION 1: GENERAL

Sec. 1.1 Scope

This standard covers materials and installation procedures for polyethylene encasement to be applied to underground installations of ductile-iron pipe. This standard also may be used for polyethylene encasement of fittings, valves, and other appurtenances to ductile-iron pipe systems.

Sec. 1.2 Purpose

The purpose of this standard is to provide purchasers, manufacturers, and constructors with the minimum requirements for polyethylene sheet and tubes to be used for external corrosion protection of buried ductile-iron pipe, fittings, and appurtenances.

Sec. 1.3 Application

This standard or sections of this standard can be referenced in specifications for the purchasing and installation of polyethylene sheet or tubes for corrosion protection of buried ductile iron pipe, fittings, and appurtenances.

SECTION 2: REFERENCES

This standard references the following documents. In their latest editions, they form a part of this standard to the extent specified within the standard. In any case of conflict, the requirements of this standard shall prevail.

ANSI†/AWWA C600—Standard for Installation of Ductile-Iron Water Mains and Their Appurtenances.

SECTION 3: DEFINITIONS

The following definitions shall apply in this standard:

1. *Constructor:* The party that furnishes the work and materials for placement or installation.

2. *Manufacturer:* The party that manufactures, fabricates, or produces materials or products.

3. *Polyethylene encasement:* The encasement of piping with polyethylene film in tube or sheet form.

4. *Linear Low-Density Polyethylene Film:* Film extruded from virgin linear low-density polyethylene raw material.

5. *High-Density, Cross-Laminated Polyethylene Film:* Film extruded from virgin high-density polyethylene raw material, which is then molecularly oriented by stretching. Two single-ply layers of the film are then laminated together with their orientations at 90° to one another to form the final product.

6. *Purchaser:* The person, company, or organization that purchases any materials or work to be performed.

SECTION 4: REQUIREMENTS

Sec. 4.1 Materials

4.1.1 *Linear low-density polyethylene film.* Linear low-density polyethylene film shall be manufactured of virgin polyethylene material conforming to the following:

4.1.1.1 Raw material requirements per ASTM D4976

Group: 2 (Linear)

Density: 0.910 to 0.935 g/cm^3

Dielectric strength: Volume resistivity, 10^{15} ohm-cm, minimum

*American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959.

†American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

Copyright by the American Water Works Association
Wed Feb 02 02:10:22 2005

4.1.1.2 Physical properties of finished film.

Tensile strength: 3,600 psi (24.8 MPa), minimum in machine and transverse direction (ASTM D882)

Elongation: 800 percent, minimum in machine and transverse direction (ASTM D882)

Dielectric strength: 800 V/mil (31.8 V/μm) thickness, minimum (ASTM D149)

Impact resistance: 600 g, minimum (ASTM D1709 Method B)

Propagation tear resistance: 2,550 gf (grams force), minimum in machine and transverse direction (ASTM D1922)

4.1.1.3 Thickness. Linear low-density polyethylene film shall have a minimum thickness of 0.008 in. (8 mil or 200 μm).

4.1.2 *High-density, cross-laminated polyethylene film.* High-density, cross-laminated polyethylene film shall be manufactured of virgin polyethylene material conforming to the following:

4.1.2.1 Raw material requirements per ASTM D4976

Group: 2 (Linear)

High-density: 0.940 to 0.960 g/cm^3

Dielectric strength: Volume resistivity, 10^{15} ohm-cm, minimum

4.1.2.2 Physical properties of finished film.

Tensile strength: 6,300 psi (43.4 MPa), minimum in machine and transverse direction (ASTM D882)

Elongation: 100 percent, minimum in machine and transverse direction (ASTM D882)

Dielectric strength: 800 V/mil (31.8 V/μm) thickness, minimum (ASTM D149)

Impact resistance: 800 g, minimum (ASTM D1709 Method B)

Propagation tear resistance: 250 gf, minimum in machine and transverse direction (ASTM D1922)

4.1.2.3 Thickness. High-density, cross-laminated polyethylene film shall have a minimum thickness of 0.004 in. (4 mil or 100 μm).

4.1.3 *Color.* Polyethylene film may be supplied with its natural color, colors including white and black, or black (weather-resistant) containing not less than 2 percent carbon black with an average particle diameter of 50 mm or less. A minimum of 2 percent of a hindered-amine ultraviolet inhibitor is required in any natural or colored film except black film containing 2 percent or more carbon black.

Sec. 4.2 Tube Size or Sheet Width

Tube size or sheet width for each pipe diameter shall be as listed in Table 1.

Sec. 4.3 Marking

4.3.1 *Marking requirements.* The polyethylene film supplied shall be clearly marked, at a minimum of every 2-ft along its length, containing the following information:

a. Manufacturer's name or trademark.
b. Year of manufacture
c. ANSI/AWWA C105/A21.5
d. Minimum film thickness and material type (LLDPE or HDCLPE).
e. Applicable range of nominal pipe diameter size(s).
f. Warning—Corrosion Protection—Repair Any Damage

Copyright by the American Water Works Association

Table 1 Polyethylene tube and sheet sizes for push-on joint pipe*

Nominal Pipe Diameter		Minimum Polyethylene Width—*in.* (*cm*)			
in.	(*mm*)	Flat Tube		Sheet	
3	(76)	14	(36)	28	(71)
4	(102)	14	(36)	28	(71)
6	(152)	16	(41)	32	(81)
8	(203)	20	(51)	40	(102)
10	(254)	24	(61)	48	(122)
12	(305)	27	(69)	54	(137)
14	(356)	30	(76)	60	(152)
16	(406)	34	(86)	68	(173)
18	(457)	37	(94)	74	(188)
20	(508)	41	(104)	82	(208)
24	(610)	54	(137)	108	(274)
30	(762)	67	(170)	134	(340)
36	(914)	81	(206)	162	(411)
42	(1,067)	81	(206)	162	(411)
48	(1,219)	95	(241)	190	(483)
54	(1,400)	108	(274)	216	(549)
60	(1,500)	108	(274)	216	(549)
64	(1,600)	121	(307)	242	(615)

* These wrap sizes should work with most push-on joint pipe and fitting bell sizes. Where bell circumferences are larger than the sheet sizes shown, the bell areas should be carefully wrapped with cut film sections, effectively lapping and securing cut edges as necessary; or, alternatively, sufficiently large tube or sheet film to effectively cover these joints should be ordered.

4.3.2 *Marking height.* Letters and numerals used for marking items *a* through *e* in Section 4.3.1. shall not be less than 1 in. in height. Item *f* in Section 4.3.1 shall be not less than 1½ in. in height.

Sec. 4.4 Installation

4.4.1 *General.* The polyethylene encasement shall prevent contact between the pipe and the surrounding backfill and bedding material, but it is not intended to be a completely airtight or watertight enclosure. All lumps of clay, mud, cinders, etc., on the pipe surface shall be removed prior to installation of the polyethylene encasement. During installation, soil or embedment material shall not be trapped between the pipe and the polyethylene.

The polyethylene film shall be fitted to the contour of the pipe creating a snug, but not tight, encasement with minimum space between the polyethylene and the pipe. Sufficient slack shall be provided in contouring to prevent stretching the polyethylene where it bridges irregular surfaces, such as bell-spigot interfaces, bolted joints, or fittings and to prevent damage to the polyethylene caused by backfilling operations. Overlaps and ends shall be secured with adhesive tape, or plastic tie straps.

For installations below the water table or in areas subject to tidal actions, tube-form polyethylene should be used with both ends thoroughly sealed with adhesive

Copyright by the American Water Works Association
Wed Feb 02 02:10:22 2005

tape or plastic tie straps at the joint overlap. Also, circumferential wraps of tape should be placed at 2 ft (0.6 m) intervals along the barrel of the pipe to minimize the space between the polyethylene and the pipe.

4.4.2 *Pipe.* This standard includes three methods of installation of polyethylene encasement on pipe. Methods A and B are for use with polyethylene tubes, and method C is for use with polyethylene sheets.

4.4.2.1 Method A. (Refer to Figure 1.) Cut polyethylene tube to a length approximately 2 ft (0.6 m) longer than the pipe section. Slip the tube around the pipe, centering it to provide a 1-ft (0.3-m) overlap on each adjacent pipe section and bunching it accordion-fashion lengthwise until it clears the pipe ends.

Lower the pipe into the trench and make up the pipe joint with the preceding section of pipe. A shallow bell hole must be made at the joints to facilitate installation of the polyethylene tube.

After assembling the pipe joint, make the overlap of the polyethylene tube. Pull the bunched polyethylene from the preceding length of pipe, slip it over the end of the new length of pipe, and secure it in place. Then slip the end of the polyethylene from the new pipe section over the end of the first wrap until it overlaps the joint at the end of the preceding length of pipe. Secure the overlap in place. Take up the slack width at the top of the pipe as shown in Figure 2 to make a snug but not tight fit along the barrel of the pipe, securing the fold at quarter points.

Cuts, tears, punctures, or other damage to the polyethylene shall be repaired as described in Sec. 4.4.5. Proceed with the installation of the next section of pipe in the same manner.

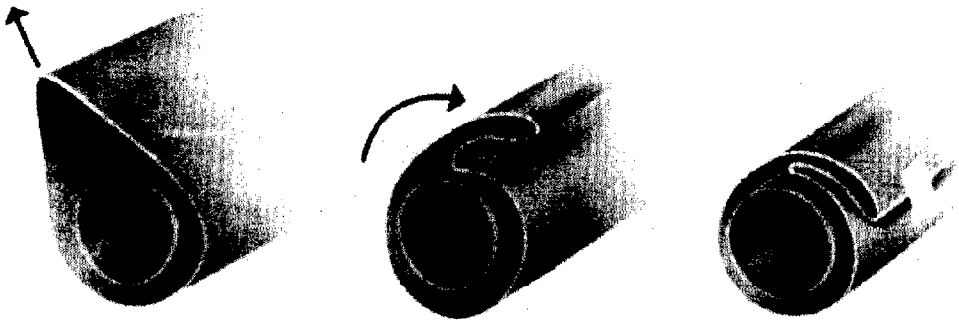
4.4.2.2 Method B. (Refer to Figure 3.) Cut polyethylene tube to a length approximately 1 ft (0.3 m) shorter than that of the pipe section. Slip the tube around the pipe, centering it to provide 6 in. (150 mm) of bare pipe at each end. Take up the slack width at the top of the pipe as shown in Figure 2 to make a snug but not tight fit along the barrel of the pipe, securing the fold at quarter points. Secure the ends as described in Sec. 4.4.1.

Before making up a joint, slip a 3-ft (0.9-m) length of polyethylene tube over the end of the preceding pipe section, bunching it accordion-fashion lengthwise. Alternatively, place a 3-ft (0.9-m) length of polyethylene sheet in the trench under the joint to be made. After completing the joint, pull the 3-ft (0.9-m) length of

One length of polyethylene tube for each length of pipe, overlapped at joint.

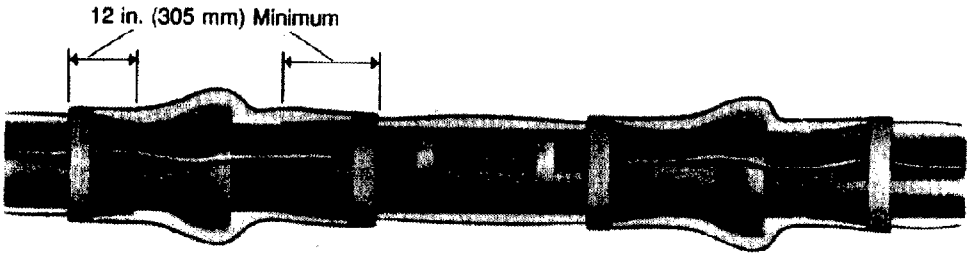
Figure 1 Installation method A

Copyright by the American Water Works Association
Wed Feb 02 02:10:23 2005



Take up the slack in the tube to make a snug but not tight fit. Fold the excess back over the top of the pipe, securing the fold at quarter points along the length of the pipe.

Figure 2 Slack-reduction procedure for installation methods A and B



Separate pieces of polyethylene tube for barrel of pipe and polyethylene tube or sheet for joints. The polyethylene over joints overlaps tube encasing barrel. (Method B is not recommended for bolted-type joints unless an additional layer of polyethylene is provided over the joint area as in methods A and C.)

Figure 3 Installation method B

polyethylene over or around the joint, overlapping the polyethylene previously installed on each adjacent section of pipe by at least 1 ft (0.3 m). Make each end snug and secure as described in Sec. 4.4.1. A shallow bell hole is necessary and shall be made at joints to facilitate the installation of the polyethylene tube or sheet.

Cuts, tears, punctures, or other damage to the polyethylene shall be repaired as described in Sec. 4.4.5. Proceed with installation of the next section of pipe in the same manner.

4.4.2.3 Method C. (Refer to Figure 4.) Cut polyethylene sheet to a length approximately 2 ft (0.6 m) longer than that of the pipe section. Center the cut length to provide a 1-ft (0.3-m) overlap on each adjacent pipe section, bunching it until it clears the pipe ends. Wrap the polyethylene around the pipe so that it circumferentially overlaps the top quadrant of the pipe. Secure the cut edge of polyethylene sheet at intervals of approximately 3 ft (0.9 m).

Copyright by the American Water Works Association
Wed Feb 02 02:10:24 2005

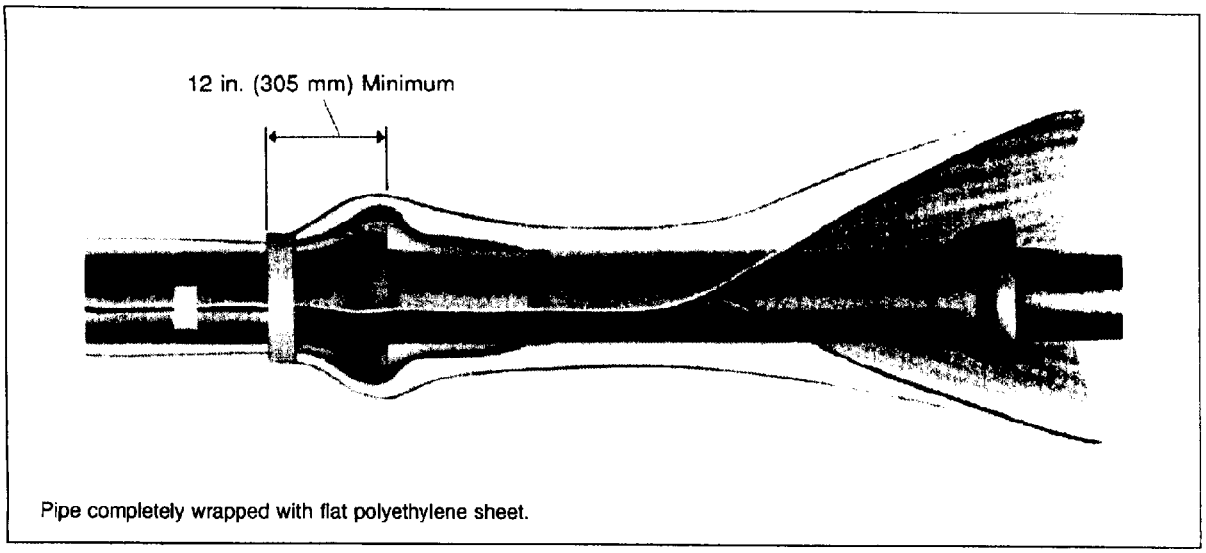


Figure 4 Installation method C

Lower the wrapped pipe into the trench and make up the pipe joint with the preceding section of pipe. A shallow bell hole is necessary and shall be made at the joints to facilitate installation of the polyethylene. After completing the joint, make the overlap and secure the ends as described in Sec. 4.4.1.

Cuts, tears, punctures, or other damage to the polyethylene shall be repaired as described in Sec. 4.4.5. Proceed with installation of the next section of pipe in the same manner.

4.4.3 *Pipe-shaped appurtenances.* Bends, reducers, offsets, and other pipe-shaped appurtenances shall be covered with polyethylene in the same manner as the pipe.

4.4.4 *Odd-shaped appurtenances.* When it is not practical to wrap valves, tees, crosses, and other odd-shaped pieces in a tube, wrap with a flat sheet or split length of polyethylene tube by passing the sheet under the appurtenance and bringing the sheet around the body. Make seams by bringing the edges of the polyethylene sheet together, folding them over twice, and taping them. Handle width and overlaps at joints as described in Sec. 4.4.2.1. Tape the polyethylene securely in place at the valve stem and other penetrations.

4.4.5 *Repairs.* Repair cuts, tears, punctures, or damage to polyethylene with adhesive tape or with a short length of polyethylene sheet, or with a tube cut open, wrapped around the pipe to cover the damaged area, and secured in place.

4.4.6 *Openings in encasement.* Provide openings for branches, service taps, blowoffs, air valves, and similar appurtenances by cutting an X in the polyethylene and temporarily folding back the film. After the appurtenance is installed, tape the slack securely to the appurtenance, and repair the cut and any other damaged areas in the polyethylene with tape. Direct service taps may also be made through the polyethylene, with any resulting damaged areas being repaired as described previously. To make direct service taps, apply two or three wraps of adhesive tape completely around the polyethylene encased pipe to cover the area where the tapping machine and chain will be mounted. This method minimizes possible damage to the polyethylene during the direct tapping procedure. After the tapping machine is mounted, the corporation stop is installed directly through the tape and polyethylene

Copyright by the American Water Works Association
Wed Feb 02 02:10:24 2005

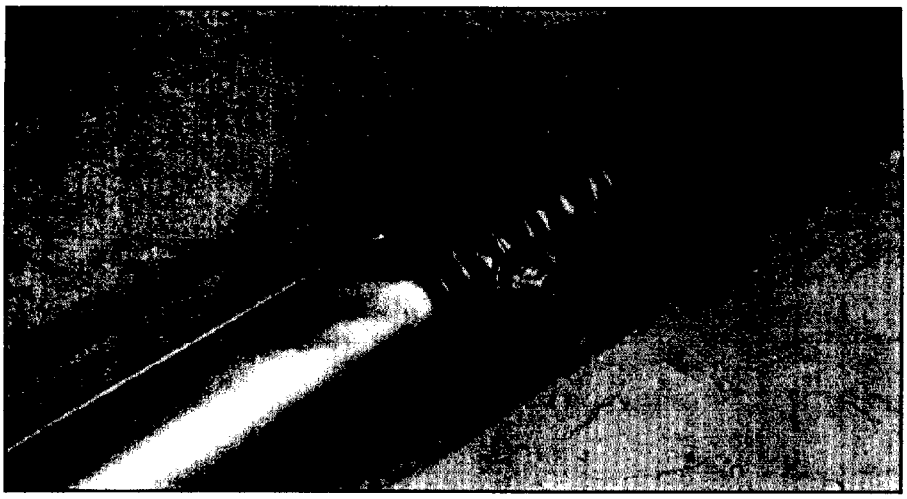

Figure 5 Preferred method for making direct service taps on PE-encased iron pipe

as shown in Figure 5. This method is very effective in eliminating damage to the polyethylene encasement caused by the tapping machine and chain during the tapping operation. After the direct tap is completed, the entire circumferential area shall be closely inspected for damage and repaired if needed.

4.4.7 *Junctions between wrapped and unwrapped pipe.* Where polyethylene-wrapped pipe joins an adjacent pipe that is not wrapped, extend the polyethylene wrap to cover the adjacent pipe for a distance of at least 3 ft (0.9 m). Secure the end with circumferential turns of adhesive tape.

Service lines of dissimilar metals shall be wrapped with polyethylene or a suitable dielectric tape for a minimum clear distance of 3 ft (0.9 m) away from the ductile-iron pipe.

4.4.8 *Backfill for polyethylene-wrapped pipe.* Use the same backfill material as that specified for pipe without polyethylene wrap, exercising care to prevent damage to the polyethylene wrapping when placing backfill. Backfill material shall be free from cinders, refuse, boulders, rocks, stones, or other material that could damage the polyethylene. In general, backfilling practice should be in accordance with the latest revision of ANSI/AWWA C600.

SECTION 5: VERIFICATION

Sec. 5.1 Inspection and Certification by Manufacturer

5.1.1 *Quality control and inspection.* The manufacturer shall establish the necessary quality control and inspection practice to ensure compliance with this standard.

5.1.2 *Manufacturer's statement.* The manufacturer shall, if required by the purchaser's specifications, provide a sworn statement that the inspection and all applicable material requirements of Section 4.1 have been met and that all results comply with the requirements of this standard.

5.1.3 *Freedom from defects.* All polyethylene film shall be clean, sound, and without defects that could impair service.

APPENDIX A

Notes on Procedures for Soil Survey Tests and Observations and Their Interpretation to Determine Whether Polyethylene Encasement Should Be Used

This appendix is for information only and is not a part of ANSI/AWWA C105/A21.5.

In the appraisal of soil and other conditions that affect the corrosion rate of ductile-iron pipe,* many factors must always be considered. They are outlined here. A method of evaluating and interpreting each factor and a method of weighing each factor to determine whether polyethylene encasement should be used are subsequently described.

These methods should be employed only by qualified personnel who are experienced in soil analysis and evaluation of conditions potentially corrosive to ductile-iron pipe. Factors such as moisture content, soil temperature, location of soil sample with respect to pipe, time between removal of soil sample and testing, and other factors can significantly affect the soil-test evaluation. For example, certain soil environments are considered to be potentially corrosive to ductile-iron pipe, and therefore, do not require evaluation to determine the need for corrosion protection. These environments include, but are not limited to, coal, cinders, muck, peat, mine wastes, and landfill areas high in foreign materials. Existing installations and the potential for stray direct-current corrosion should also be a part of the evaluation.

Soil Survey Tests and Observations

Factors to consider when determining the need for polyethylene encasement of pipe are outlined below. A discussion of each point follows the outline.

1. Earth resistivity.
   a. Four-pin
   b. Single-probe
   c. Saturated-sample (soil-box)
2. pH.
3. Oxidation-reduction (redox) potential.
4. Sulfides.
   a. Azide (qualitative)
5. Moisture content (relative).
   a. Prevalence
6. Soil description.
   a. Particle size
   b. Uniformity
   c. Type
   d. Color
7. Potential stray direct current.
   a. Nearby cathodic protection utilizing rectifiers
   b. Railroads (electric)
   c. Industrial equipment, including welding equipment
   d. Mine transportation equipment
8. Experience with existing installations in the area.

*NOTE: The information contained in appendix A is also applicable to gray-iron pipe. Although gray-iron pipe is no longer produced in the United States, many miles of this product remain in service.

1. *Earth resistivity.* There are three methods for determining earth resistivity: four-pin, single-probe, and soil-box. In the field, a four-pin determination should be made with pins spaced at approximate pipe depth. This method yields an average of resistivity from the surface to a depth equal to pin spacing. However, results are sometimes difficult to interpret where dry topsoil is underlain with wetter soils and where soil types vary with depth. The Wenner configuration is used with a soil-resistance meter, which is available with varying ranges of resistance. For all-around use, a meter with a capacity of up to 10^4 ohms is suggested, because it permits both field and laboratory testing of most soils.

Because of this difficulty in interpretation, the same meter may be used with a single probe that yields resistivity at the point of the probe. A boring is made into the subsoil allowing the probe to be pushed into the soil at the desired depth.

Because the soil may not be typically wet, a sample should be removed for saturated resistivity determination. This may be accomplished with a laboratory unit that permits the introduction of water to saturation, therefore simulating saturated field conditions. The unit is used in conjunction with a soil-resistance meter.

The interpretation of the results of resistivity measurements is extremely important. A determination based on a four-pin reading with dry topsoil averaged with wetter subsoil would probably be inaccurate. Only by determining the resistivity in soil at pipe depth can an accurate interpretation be made. Also, the local situation should be determined concerning groundwater table, the presence of shallow groundwater, and the approximate percentage of time the soil is likely to be water saturated.

With ductile-iron pipe, corrosion protection provided by products of corrosion is enhanced if there are dry periods during each year. Dry periods seem to permit hardening, or toughening, of the corrosion scale or products, which then become impervious and serve as better insulators.

In making field determinations of resistivity, temperature is important. The resistivity increases as the temperature decreases. As the water in the soil approaches freezing, resistivity increases greatly and, therefore, is not reliable. Field determinations under frozen soil conditions should be avoided. Reliable results under these conditions can be obtained only by the collection of suitable subsoil samples for analysis in laboratory conditions at a proper temperature.

Interpretation of resistivity data. Because of the wide variance in results obtained using the methods described, it is difficult to interpret any single reading without knowing which method was used to obtain the reading. The interpretation should be based on the lowest reading obtained, with consideration to other conditions, such as typical moisture content of the soil. Because of the lack of exact correlation between experiences and resistivity, it is necessary to assign ranges of resistivity rather than specific numbers. Table A.1 shows the points assigned to various ranges of resistivity. These points, when considered along with points assigned to other soil characteristics (also shown in Table A.1), are significant.

2. *pH.* In the pH range of 0.0 to 4.0, soil serves well as an electrolyte. In the pH range of 6.5 to 7.5, soil conditions are optimum for sulfate reduction. In the pH range of 8.5 to 14.0, soils are generally high in dissolved salts, yielding a low soil resistivity.

In testing pH, a combination pH electrode is pushed into the soil sample, and a direct reading is made, following suitable temperature setting on the instrument. Normal procedures are followed for standardization.

Table A.1 Soil-test evaluation

Soil Characteristics Based on Samples Taken Down to Pipe Depth	Points*
Resistivity—ohm-cm (based on water-saturated soil box)	
<1,500	10
≥1,500–1,800	8
>1,800–2,100	5
>2,100–2,500	2
>2,500–3,000	1
>3,000	0
pH:	
0–2	5
2–4	3
4–6.5	0
6.5–7.5	0†
7.5–8.5	0
>8.5	3
Redox potential:	
> +100 mV	0
+50 to +100 mV	3.5
0 to +50 mV	4
Negative	5
Sulfides:	
Positive	3.5
Trace	2
Negative	0
Moisture:	
Poor drainage, continuously wet	2
Fair drainage, generally moist	1
Good drainage, generally dry	0

*Ten points indicates that soil is corrosive to ductile-iron pipe; protection is needed.

†If sulfides are present and low or negative redox-potential results are obtained, add three points for this range.

3. *Oxidation-reduction (redox) potential.* The redox potential of a soil is significant, because the most common sulfate-reducing bacteria can live only in anaerobic conditions. A redox potential greater than +100 mV demonstrates that the soil is sufficiently aerated, preventing sulfate reducers from forming. Potentials of 0 to +100 mV may or may not indicate anaerobic conditions; however, a negative redox potential definitely indicates the anaerobic conditions in which sulfate reducers thrive. The redox test is performed using a pH/mV meter with a combination ORP electrode inserted into the soil sample. It should be noted that soil samples removed from a boring or excavation can undergo a change in redox potential when exposed to

Copyright by the American Water Works Association
Wed Feb 02 02:10:26 2005

air. These samples should be tested immediately after the excavation. Heavy clays, muck, and organic soils are often anaerobic. For this reason, these soils should be regarded as potentially corrosive.

4. *Sulfides.* The sulfide determination is recommended because of its field expediency. A positive sulfide reaction reveals a potential problem caused by sulfate-reducing bacteria. The sodium azide–iodine qualitative test is used to identify sulfides. In this determination, a solution of 3 percent sodium azide in a 0.1N iodine solution is introduced into a test tube containing a sample of the soil. Sulfides catalyze the reaction between sodium azide and iodine resulting in nitrogen. If strong bubbling or foaming results, sulfides are present, as are sulfate-reducing bacteria. If very slight bubbling is noted, sulfides are probably present in small concentration, and the result is noted as a trace.

5. *Moisture content.* Because prevailing moisture content is extremely important to all soil corrosion, this condition must be determined. It is not necessary that the specific moisture content of a soil sample be determined, because the content probably varies throughout the year. However, local authorities should observe the soil moisture conditions many times during the year. (Although mentioned in item 1, Earth Resistivity, this variability factor is reiterated to emphasize the importance of notation.)

6. *Soil description.* In each investigation, soil types should be completely described. The description should include color and physical characteristics, such as particle size, plasticity, friability, and uniformity. Observation and testing will reveal whether the soil is high in organic content; this should be noted. In a given area, corrosivity may often be reflected in certain types and colors of soil. This information is valuable for future investigations or for determining suspect soils.

Soil uniformity is important because of the possible development of local corrosion cells caused by the difference in potential, such as different soil types contacting the pipe. The same is true for uniformity of aeration. If one segment of soil contains more oxygen than a neighboring segment, a corrosion cell can develop from the difference in potential. This cell is known as a differential aeration cell.

There are several basic types of soils that should be noted in the soil description: sand, loam, silt, clay, and muck. In addition, unusual soils, such as peat or soils high in foreign material, should be noted.

7. *Potential stray direct current.* All soil surveys should consider the possibility of stray direct current which might interfere with the ductile-iron-pipe installation. The widespread use of rectifiers and ground beds for cathodic protection of underground structures has increased the potential of stray direct current. The proximity of these cathodic protection systems should be noted. Among other potential sources of stray direct current are electric railways, industrial equipment (including welding equipment), and mine-transportation equipment.

Normally, the amount of stray current influence from cathodic protection systems on an electrically discontinuous ductile iron pipeline will be negligible. It is not detrimental to the expected life of the system, unless the pipeline comes close to an impressed-current, cathodic-protection anode bed where the current density is high. When ductile iron pipelines are exposed to high-density stray current environments, the pipeline should be rerouted or the anode bed relocated. If neither of these options is feasible, the ductile iron pipe in this area should be electrically bonded together, electrically isolated from adjacent pipe, polyethylene encased, and appropriate test leads and "current drain" installed.

Copyright by the American Water Works Association
Wed Feb 02 02:10:26 2005

8. *Experience with existing installations.* The best information on soil corrosivity with respect to ductile-iron pipe results from experience with this material in the area under investigation. Every effort should be made to acquire these data by questioning local officials and, if possible, by observing existing installations.

Soil-Test Evaluation

When the soil-test procedures described in this standard are employed, the following tests are used in evaluating corrosivity of the soil: resistivity, pH, redox potential, sulfides, and moisture. For each of these tests, results are categorized according to their contribution to corrosivity. Point values are assigned, based on experience with ductile-iron pipe (see Table A.1). When results of these five tests/observations are available, the assigned points are totaled. If the sum is equal to 10 or more, the soil is corrosive to ductile-iron pipe, and protection against exterior corrosion should be provided. This system of evaluation is limited to soil corrosion and does not include consideration of stray direct current.

General. These notes address only ductile-iron pipe, the soil environment in which the pipe will serve, and the methods of determining a need for polyethylene encasement.

Uniquely Severe Environments

Research has shown that polyethylene encasement alone is a viable corrosion protection system for ductile- and gray-iron pipe in most environments. However, other options should be considered for environments where all the following characteristics co-exist: (1) soil resistivity ≤500 ohm-cm; (2) anaerobic conditions in which sulfate-reducing bacteria thrive [neutral pH (6.5 to 7.5), low or negative redox-potential (negative to +100 mV), and the presence of sulfides (positive or trace)]; and (3) water table intermittently or continually above the invert of the pipe.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

Foreword

This foreword is for information only and is not a part of ANSI/AWWA C150/A21.50.

I. Introduction

I.A. *Background.* The purpose of this standard is to provide pipeline designers with a recommended design procedure and associated tabular data necessary to establish the wall thickness(es) required for buried ductile-iron pipe based on the type of pipe embedment, depths of trench cover, live load conditions, internal working pressures, and surge conditions appropriate for the specific pipeline project. Once the required wall thickness(es) has been established, the ductile-iron pipe should be specified to be manufactured in accordance with ANSI*/AWWA C151/A21.51. ANSI/AWWA C151/A21.51 contains options that must be addressed in the purchaser's specifications in response to site-specific project requirements.

Although ANSI/AWWA C150/A21.50 is commonly used for designing ductile-iron pipe for services other than water, users are also directed to ASTM† A746, Standard Specification for Ductile Iron Gravity Sewer Pipe.

I.B. *History.* American National Standards Committee A21, Cast-Iron Pipe and Fittings, was organized in 1926 under the sponsorship of the American Gas Association (A.G.A), the American Society for Testing and Materials (ASTM), the American Water Works Association (AWWA), and the New England Water Works Association (NEWWA). Between 1972 and 1984, the cosecretariats were A.G.A, AWWA, and NEWWA, with AWWA serving as administrative secretariat. In 1984, the committee became an AWWA committee with the name of American Water Works Association Standards Committee A21 on Ductile-Iron Pipe and Fittings. In 1988, NEWWA withdrew as a separate secretariat; however, it continues to maintain its representation on the AWWA Committee A21. The committee remains cosponsored by A.G.A for gas-related activities.

The present scope of AWWA Committee A21 activity is the development of standards and manuals addressing ductile-iron pressure pipe for gas, water, and other liquids, and ductile-iron and gray-iron fittings for use with such pipe. These standards and manuals include design, dimensions, materials, coatings, linings, joints, accessories, and methods of inspection and testing.

The work of AWWA Committee A21 is conducted by subcommittees. The scope of Subcommittee 1, Pipe, includes the periodic review of all current A21 standards for pipe, the preparation of revisions and new standards when needed, as well as other matters pertaining to pipe standards.

The first edition of A21.50, American National Standard for the Thickness Design of Ductile-Iron Pipe, was issued in 1965, and revisions were issued in 1971, 1976, 1981, and 1991. The standard was reaffirmed without revision in 1986. Subcommittee 1 reviewed the 1991 edition and submitted a proposed revision to AWWA Standards Committee A21 in 1995.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International

*American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

†American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959.

Copyright by the American Water Works Association
Wed Feb 02 02:12:36 2005

(NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other members of the original consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA) and the Association of State Drinking Water Administrators (ASDWA) joined later.

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.* Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.
3. Two standards developed under the direction of NSF, ANSI†/NSF‡ 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.
4. Other references, including AWWA standards, *Food Chemicals Codex*, *Water Chemicals Codex*,§ and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

AWWA C150-96 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements, including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues. Currently, there are no special issues related to this standard.

---

*Persons in Canada, Mexico, and non-North American countries should contact the appropriate authority having jurisdiction.

†American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser Options and Alternatives.* As noted in Sec. I.A of the foreword, ANSI/AWWA C151/A21.51 contains options that must be addressed in the purchaser's specifications in response to site-specific requirements for ductile-iron pipe.

III.B. *Modification to Standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. Major revisions made to the standard in this edition include the following:

1. The format has been changed to AWWA standard style.
2. The acceptance clause (Sec. I.C) has been revised to approved wording.
3. The truck load equation (Eq 5) and the surface load factor (Eq 6) have been modified to allow for a correct distribution of units.
4. Table 6, Surface load factors for single truck on unpaved road, has been changed to match the revised surface load factor equation (Eq 6).
5. The statement concerning surge allowance in the hoop stress formula (Sec. 4.1.2 and Sec. 4.2.2) has been modified to note that if anticipated surge pressures are other than 100 psi (689 kPa), the actual anticipated pressure should be used.

V. Comments. If you have any comments or questions about this standard, please call the AWWA Standards and Materials Development Department, (303) 794-7711 ext. 6283, FAX (303) 795-1440, or write to the department at 6666 W. Quincy Ave., Denver, CO 80235.

ANSI/AWWA C150/A21.50-96
(Revision of ANSI/AWWA C150/A21.50-91)

AMERICAN NATIONAL STANDARD FOR

THICKNESS DESIGN OF DUCTILE-IRON PIPE

SECTION 1: GENERAL

Sec. 1.1 Scope

This standard covers the thickness design of ductile-iron pipe complying with the requirements of ANSI*/AWWA C151/A21.51, Ductile-Iron Pipe, Centrifugally Cast, for Water.

Section 4.1 outlines the design procedure and Sec. 4.2 gives a design example.

Section 4.3 explains the basis of design.

As opposed to using procedures in Sec. 4.1 or Sec. 4.3, the designer may reference Tables 12 through 14 directly.

Table 12 lists thicknesses for standard laying conditions and certain depths of cover.

Table 13 lists thicknesses for 150 psi–350 psi (1,034 kPa–2,413 kPa)† water working pressure.

The greater thickness from Table 12 or Table 13 for given trench load or internal pressure should be used.

Table 14 lists working pressures and maximum depths of cover for standard laying conditions and standard pressure classes.

Table 15 lists special thickness classes of ductile-iron pipe.

*American National Standards Institute Inc., 11 W. 42nd St., New York, NY 10036.

†Metric conversions given in this standard are direct conversions of US customary units and are not those specified in International Organization for Standardization (ISO) standards.

Copyright by the American Water Works Association
Wed Feb 02 02:12:37 2005

Sec. 1.2 Purpose

The main purpose of this standard is to provide the minimum requirements for the thickness design of ductile-iron pipe, including basis of design and design procedure.

Sec. 1.3 Application

This standard can be referenced in specifications for the thickness design of ductile-iron pipe. The stipulations of this standard apply when this document has been referenced and then only to the thickness design of ductile-iron pipe.

SECTION 2: REFERENCES

This standard references the following documents. In their latest editions, these documents form a part of this standard to the extent specified within the standard. In any case of conflict, the requirements of this standard shall prevail.

AASHTO T99—Standard Method of Test for the Moisture-Density Relations of Soils Using a 5.5 lb (2.5 kg) rammer, 12 in. (305 mm) drop.

ANSI/AWWA C151/A21.51—American National Standard for Ductile-Iron Pipe, Centrifugally Cast, for Water.

ASTM* A746—Standard Specification for Ductile Iron Gravity Sewer Pipe.

SECTION 3: DEFINITIONS

This standard has no applicable information for this section.

SECTION 4: REQUIREMENTS

Sec. 4.1 Procedure for Calculating Thickness

The thickness of ductile-iron pipe is determined by considering trench load and internal pressure separately.

4.1.1 *Step 1—Design for trench load.*

a. Determine trench load P_v. Table 1 gives trench load, including earth load P_e, plus truck load P_t, for 2.5 ft–32 ft (0.8 m–9.8 m) cover.

b. Determine the standard laying condition from the descriptions in Table 2 and select the appropriate table for diameter–thickness ratios from Tables 7 through 11. Each table lists diameter–thickness ratios calculated for both bending stress and deflection over a range of trench loads.

c. For bending-stress design, enter the column headed "Bending-Stress Design" in the appropriate table of Tables 7 through 11, and locate the tabulated trench load P_v nearest to the calculated P_v from Sec. 4.1.1.a. (If the calculated P_v is halfway between two tabulated values, use the larger P_v value.)

*American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959.

STD.AWWA C150/A21.50-ENGL 1996 ■ 0783350 0504729 267 ■

Select the corresponding D/t value for this P_v.

Divide the pipe's outside diameter D (Table 5) by the D/t value to obtain net thickness t.

d. For deflection design, enter the column headed "Deflection Design" in the appropriate table of Tables 7 through 11, and locate the tabulated trench load P_v nearest to the calculated P_v from Sec. 4.1.1.a. (If the calculated P_v is less than the minimum P_v listed in the table, design for trench load is not controlled by deflection and this determination need not be completed.) If the calculated P_v is halfway between two tabulated values, use the larger P_v value.

Select the corresponding D/t_1 value for this P_v.

Divide the pipe's outside diameter D (Table 5) by the D/t_1 value to obtain minimum manufacturing thickness t_1. Deduct 0.08 in. (2.0 mm) service allowance to obtain net thickness t.

NOTE: Service allowance equals 0.08 in. (2.0 mm) for all sizes of ductile-iron pipe.

e. Compare the net thicknesses from steps c and d and select the larger of the two. This will be the net thickness required for trench load.

4.1.2 *Step 2—Design for internal pressure.* Calculate the net thickness required for internal pressure using the equation for hoop stress:

$$t = \frac{P_i D}{2S}$$

Where:

t = net thickness, in. (mm)
P_i = design internal pressure, psi (kPa) = 2 ($P_w + P_s$)
P_w = working pressure, psi (kPa)
P_s = surge allowance, 100* psi (689 kPa)
D = outside diameter of pipe, in. (mm)
S = minimum yield strength in tension = 42,000 psi (289,590 kPa)

*(If anticipated surge pressures are other than 100 psi (689 kPa), the actual anticipated pressure should be used.)

4.1.3 *Step 3—Selection of net thickness and addition of allowances.*

a. Select the net thickness t from step 1 or step 2, whichever thickness is larger.

b. Add the service allowance of 0.08 in. (2.0 mm) to the net thickness t. The resulting thickness is the minimum manufacturing thickness t_1.

c. Add the casting allowance from Table 3 to the minimum manufacturing thickness t_1. The resulting thickness is the total calculated thickness.

4.1.4 *Step 4—Selection of standard pressure class.* Use the total calculated thickness from Sec. 4.1.3.c to select a standard pressure-class thickness from Table 5. When the calculated thickness is between two nominal thicknesses, select the larger of the two.

When specifying and ordering pipe, use the pressure class listed in Table 5 for this nominal thickness.

NOTE: On specific projects, manufacturers may be willing to furnish pipe with thicknesses that fall between standard classes.

4.1.5 *Alternative procedure.* The appropriate standard pressure class may also be determined by using the Design Equations in Sec. 4.3.

Copyright by the American Water Works Association
Wed Feb 02 02:12:37 2005

Sec. 4.2 Design Example for Calculating Thickness

Problem: Calculate the thickness for 30-in. (762-mm) ductile-iron pipe bedded in loose soil for a minimum depth of 4 in. (100 mm), backfill lightly consolidated to top of pipe, laying condition Type 3, under 10 ft (3 m) of cover for a working pressure of 150 psi (1,034 kPa).

4.2.1 *Step 1—Design for trench load.*

a. Earth load (Table 1) P_e = 8.3 psi
Truck load (Table 1) P_t = 0.7 psi
Trench load, $P_v = P_e + P_t$ = 9.0 psi

b. Select Table 9 for diameter–thickness ratios for laying condition Type 3.

c. Entering P_v of 9.0 psi in Table 9, the bending-stress design requires D/t of 163. From Table 5, diameter D of 30-in. pipe is 32.00 in.

Net thickness t for bending stress = $D/(D/t)$ = 32.00/163 = 0.20 in.

d. Also, from Table 9, the deflection design requires D/t_1 of 136.

Minimum manufacturing thickness t_1 for deflection design:

$$t_1 = \frac{D}{\frac{D}{t_1}} = \frac{32.00}{136} = 0.24 \text{ in.}$$

Deduct service allowance −0.08 in.
Net thickness t for deflection control = 0.16 in.

e. The larger net thickness is 0.20 in., obtained by the design for bending stress.

4.2.2 *Step 2—Design for internal pressure.*

$P_i = 2.0\ (P_w + P_s)$ = 2.0 (working pressure + 100 psi surge allowance)

(If anticipated surge pressures are other than 100 psi [689 kPa], then the actual anticipated pressures should be used.)

$$P_i = 2.0\ (150 + 100) = 500 \text{ psi}$$

$$t = \frac{P_i D}{2S} = \frac{500 \times 32.00}{2 \times 42{,}000} = 0.19 \text{ in.}$$

Net thickness t for internal pressure is 0.19 in.

4.2.3 *Step 3—Selection of net thickness and addition of allowances.* The larger of the thicknesses is given by the design for trench load, Step 1, and 0.20 in. is selected.

Net thickness = 0.20 in.
Service allowance = 0.08 in.
Minimum manufacturing thickness = 0.28 in.
Casting allowance = 0.07 in.
Total calculated thickness = 0.35 in.

Copyright by the American Water Works Association
Wed Feb 02 02:12:38 2005

STD.AWWA C150/A21.50-ENGL 1996 ■ 0783350 0504731 915 ■

4.2.4 *Step 4—Selection of nominal thickness and standard pressure class.* The total calculated thickness of 0.35 in. is larger than 0.34 in., Class 150. Therefore, Class 200 is selected for specifying and ordering.

Sec. 4.3 Design Method

4.3.1 *Ductile-iron pipe thickness.* The thickness of ductile-iron pipe is determined by considering trench load and internal pressure separately.

Calculations are made for the thicknesses required to resist the bending stress and the deflection caused by trench load. The larger of the two is selected as the thickness required to resist trench load. Calculations are then made for the thickness required to resist the hoop stress of internal pressure.

The larger of these is selected as the net design thickness. To this net thickness is added a service allowance to obtain the minimum manufacturing thickness and a casting allowance to obtain the total calculated thickness.

The nominal thickness and the standard pressure class for specifying and ordering are selected from the table of nominal thicknesses for standard pressure classes (Table 5).

The reverse of the preceding procedure is used to determine the rated working pressure and maximum depth of cover for pipe of a given pressure class.

4.3.2 *Trench load P_v.* Trench load is expressed as vertical pressure in pounds per square inch (kilopascals) and is equal to the sum of earth load P_e and truck load P_t.

4.3.3 *Earth load P_e.* Earth load is computed by Eq 4 for the weight of the unit prism of soil with a height equal to the distance from the top of the pipe to the ground surface. The unit weight of backfill soil is taken to be 120 lb/ft^3 (18.85 kN/m^3). If the designer anticipates additional loads, the design load should be increased accordingly.

4.3.4 *Truck load P_t.* The truck loads shown in Table 1 were computed by Eq 5 using the surface-load factors in Table 6 and the reduction factors R from Table 4 for a single AASHTO H-20 truck on unpaved road or flexible pavement, 16,000-lb (71,170-N) wheel load, and 1.5 impact factor. The surface-load factors in Table 6 were calculated by Eq 6 for a single concentrated wheel load centered over an effective pipe length of 3 ft (0.914 m).

4.3.5 *Design for trench load.* Tables 7 through 11, the diameter–thickness ratios tables used to design for trench load, were computed with Eqs 2 and 3. Equation 2 is based on the bending stress at the bottom of the pipe. The design-bending stress f is 48,000 psi (331 × 10^3 kPa), which provides at least a 1.5 safety factor based on minimum ring yield strength and a 2.0 safety factor based on ultimate strength. Equation 3 is based on the deflection of the pipe ring section. The design deflection Δx is 3 percent of the outside diameter of the pipe, which is well below the deflection that might damage cement linings. Design values of the trench parameters E', K_b, and K_x are given in Table 2.

Tables similar to Tables 7 through 11 may be compiled for laying conditions other than those shown in this standard by calculating the trench loads P_v for a series of diameter–thickness ratios, D/t and D/t_1, using Eqs 2 and 3 with values of E', Kb, and K_x appropriate to the bedding and backfill conditions.

Design Equations

$$t = \frac{P_i D}{2S} \qquad \text{(Eq 1)}$$

$$P_v = \frac{f}{3\left(\frac{D}{t}\right)\left(\frac{D}{t}-1\right)\left[K_b - \frac{K_x}{\frac{8E}{E'\left(\frac{D}{t}-1\right)^3}+0.732}\right]} \qquad \text{(Eq 2)}$$

$$P_v = \frac{\frac{\Delta x}{D}}{12\,K_x}\left[\frac{8E}{\left(\frac{D}{t_1}-1\right)^3}+0.732E'\right] \qquad \text{(Eq 3)}$$

$$P_e = \frac{wH}{a} \qquad \text{(Eq 4)}$$

$$P_t = RF\frac{CP}{bD} \qquad \text{(Eq 5)}$$

$$C = 1 - \frac{2}{\pi}\arcsin\left(H\sqrt{\frac{A^2+B^2+H^2}{(A^2+H^2)(B^2+H^2)}}\right) + \frac{2}{\pi}\left(\frac{A{\cdot}H{\cdot}B}{\sqrt{A^2+H^2+B^2}}\right)\left(\frac{1}{A^2+H^2}+\frac{1}{B^2+H^2}\right) \qquad \text{(Eq 6)}$$

NOTE: In Eq 6, angles are in radians.

Sec. 4.4 Explanation of Symbols Used in Design Equations

A = Outside radius of pipe. For A in feet, D in inches: $A = D/24$ (For A in metres, D in millimetres: $A = D/2{,}000$)
a = Conversion factor. For pounds per square foot to pounds per square inch: $a = 144$ (For kilonewtons per square metre to kilopascals: $a = 1$)
B = 1.5 ft (0.457 m)
b = Effective pipe length: 36 in. (0.914 m)
C = Surface load factor: see Table 6.
D = Outside diameter, in inches (millimetres): see Table 5.
E = Modulus of elasticity: 24×10^6 psi (165.5×10^6 kPa)
E' = Modulus of soil reaction, in pounds per square inch (kilopascals): see Table 2.
F = Impact factor: 1.5
f = Design bending stress: 48,000 psi (331×10^3 kPa)
H = Depth of cover, in feet (metres)
K_b = Bending moment coefficient: see Table 2.

K_x = Deflection coefficient: see Table 2.
P = Wheel load: 16,000 lb (71,170 N)
P_e = Earth load, in pounds per square inch (kilopascals)
P_i = Design internal pressure, in pounds per square inch (kilopascals): P_i = 2 (working pressure + 100 psi [689 kPa] surge allowance)
P_t = Truck load, in pounds per square inch (kilopascals)
P_v = Trench load, in pounds per square inch (kilopascals): $P_v = P_e + P_t$
R = Reduction factor, which takes account of the fact that the part of the pipe directly below the wheels is aided in carrying the truck load by adjacent parts of the pipe that receive little or no load from the wheels: see Table 4.
S = Minimum yield strength in tension: 42,000 psi (289,590 kPa)
t = Net thickness, in inches (millimetres)
t_1 = Minimum manufacturing thickness, in inches: $t_1 = t + 0.08$ (in millimetres: $t_1 = t + 2$)
w = Soil weight: 120 lb/ft^3 (18.85 kN/m^3)
Δx = Design deflection, in inches (millimetres): $\Delta x = 0.03D$

Sec. 4.5 Special Thickness Classes

For design conditions not covered in Tables 12, 13, and 14, special (formerly standard) thickness classes shown in Table 15 continue to be available.

SECTION 5: VERIFICATION

This standard has no applicable information for this section.

SECTION 6: DELIVERY

This standard has no applicable information for this section.

Table 2 Design values for standard laying conditions

Laying Condition*	Description	E' psi	Bedding Angle deg	K_b	K_x
Type 1†	Flat-bottom trench.‡ Loose backfill.	150	30	0.235	0.108
Type 2	Flat-bottom trench. Backfill lightly consolidated to centerline of pipe.	300	45	0.210	0.105
Type 3	Pipe-bedded in 4-in.-minimum loose soil.§ Backfill lightly consolidated to top of pipe.	400	60	0.189	0.103
Type 4	Pipe bedded in sand, gravel, or crushed stone to depth of ⅛ pipe diameter. 4-in. minimum. Backfill compacted to top of pipe. (Approximately 80 percent Standard Proctor, AASHTO T-99)**	500	90	0.157	0.096
Type 5	Pipe bedded to its centerline in compacted granular material, 4-in. minimum under pipe. Compacted granular or select material§ to top of pipe. (Approximately 90 percent Standard Proctor, AASHTO T-99)**	700	150	0.128	0.085

NOTES:

1) Consideration of the pipe-zone embedment conditions included in this table may be influenced by factors other than pipe strength. For additional information see ANSI/AWWA C600, Standard for Installation of Ductile-Iron Water Mains and Their Appurtenances.

2) To convert pounds per square inch (psi) to kilopascals (kPa), multiply by 6.895.

*See Figure 1.

†For pipe 14 in. (356 mm) and larger, consideration should be given to the use of laying conditions other than Type 1.

‡Flat-bottom is defined as "undisturbed earth."

§Loose soil or select material is defined as "native soil excavated from the trench, free of rocks, foreign material, and frozen earth."

**AASHTO T-99, "Standard Method of Test for the Moisture–Density Relations of Soils Using a 5.5 lb (2.5 kg) Rammer and a 12 in. (305 mm) Drop." Available from the American Association of State Highway and Transportation Officials, 444 N. Capital St. N.W., Washington, DC 20001.

Table 3 Allowances for casting tolerance

Size in.	Casting Allowance in.
3–8	0.05
10–12	0.06
14–42	0.07
48	0.08
54–64	0.09

NOTE: To convert inches (in.) to millimetres (mm), multiply by 25.4.

Table 4 Reduction factors R for truck load calculations

Size *in.*	Depth of Cover—*ft*			
	<4	4–7	>7–10	>10
	Reduction Factor			
3–12	1.00	1.00	1.00	1.00
14	0.92	1.00	1.00	1.00
16	0.88	0.95	1.00	1.00
18	0.85	0.90	1.00	1.00
20	0.83	0.90	0.95	1.00
24–30	0.81	0.85	0.95	1.00
36–64	0.80	0.85	0.90	1.00

NOTE: To convert inches (in.) to millimetres (mm), multiply by 25.4; to convert feet (ft) to metres (m), multiply by 0.3048.

Table 5 Nominal thicknesses for standard pressure classes of ductile-iron pipe

Size *in.*	Outside Diameter *in.*	Pressure Class				
		150	200	250	300	350
		Nominal Thickness—*in.*				
3	3.96	—	—	—	—	0.25*
4	4.80	—	—	—	—	0.25*
6	6.90	—	—	—	—	0.25*
8	9.05	—	—	—	—	0.25*
10	11.10	—	—	—	—	0.26
12	13.20	—	—	—	—	0.28
14	15.30	—	—	0.28	0.30	0.31
16	17.40	—	—	0.30	0.32	0.34
18	19.50	—	—	0.31	0.34	0.36
20	21.60	—	—	0.33	0.36	0.38
24	25.80	—	0.33	0.37	0.40	0.43
30	32.00	0.34	0.38	0.42	0.45	0.49
36	38.30	0.38	0.42	0.47	0.51	0.56
42	44.50	0.41	0.47	0.52	0.57	0.63
48	50.80	0.46	0.52	0.58	0.64	0.70
54	57.56	0.51	0.58	0.65	0.72	0.79
60	61.61	0.54	0.61	0.68	0.76	0.83
64	65.67	0.56	0.64	0.72	0.80	0.87

NOTE: To convert inches (in.) to millimetres (mm), multiply by 25.4.

*Calculated thicknesses for these sizes and pressure ratings are less than those shown above. (See Table 13 for actual calculated thicknesses.) Presently these are the lowest nominal thicknesses available in these sizes.

Pressure classes are defined as the rated water working pressure of the pipe in pounds per square inch (psi). The thicknesses shown are adequate for the rated water working pressure plus a surge allowance of 100 psi (689 kPa). Calculations are based on a minimum yield strength in tension of 42,000 psi (289,590 kPa) and 2.0 safety factor times the sum of working pressure and 100 psi (689 kPa) surge allowance.

Thickness can be calculated for rated water working pressure and surges other than the above by use of the formula shown in Sec. 4.1.2.

Ductile-iron pipe is available for water working pressures greater than 350 psi (2,413 kPa).

Pipe is available with thicknesses greater than Pressure Class 350. See Table 15.

Lowest nominal thicknesses shown in Table 15.1 of ANSI/AWWA C115/A21.15 for threaded flanged pipe are still required.

Lowest nominal thicknesses shown in ANSI/AWWA C606 for pipe with grooved and shouldered joints are still required.

NOTES:

1. To convert inches (in.) to millimetres (mm), multiply by 25.4; to convert pounds per square inch (psi) to kilopascals (kPa), multiply by 6.895.
2. The thicknesses shown are adequate for the rated working pressure plus a surge allowance of 100 psi (689 kPa). Calculations are based on a minimum yield strength in tension of 42,000 psi (289,590 kPa) and a 2.0 safety factor times the sum of working pressure and 100 psi (689 kPa) surge allowance.

*Total calculated thickness includes service allowance and casting tolerance added to net thickness.

NOTE: To convert inches (in.) to millimetres (mm), multiply by 25.4; to convert feet (ft) to metres (m), multiply by 0.3048; and to convert pounds per square inch (psi) to kilopascals (kPa), multiply by 6.895.

*Ductile-iron pipe is adequate for the rated working pressure indicated for each nominal size plus a surge allowance of 100 psi (689 kPa). Calculations are based on a 2.0 safety factor times the sum of working pressure and 100 psi (689 kPa) surge allowance. Ductile-iron pipe for working pressures higher than 350 psi (2,413 kPa) is available.

†An allowance for a single H-20 truck with 1.5 impact factor is included for all depths of cover.

‡Calculated maximum depth of cover exceeds 100 ft (30.5 m).

§Minimum allowable depth of cover is 3 ft (0.9 m).

**For pipe 14 in. (356 mm) and larger, consideration should be given to the use of laying conditions other than Type 1.

AWWA STANDARD

FOR

POLYVINYL CHLORIDE (PVC) PRESSURE PIPE AND FABRICATED FITTINGS, 4 IN. THROUGH 12 IN. (100 mm THROUGH 300 mm), FOR WATER DISTRIBUTION

Effective date: Feb. 1, 1998.
First edition approved by AWWA Board of Directors June 8, 1975.
This edition approved June 15, 1997.
Approved by American National Standards Institute Dec. 1, 1997.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

Foreword

This foreword is for information only and is not a part of AWWA C900.

I. Introduction.

I.A. *Background.* This standard pertains to 4-in. through 12-in. (100-mm through 300-mm) polyvinyl chloride (PVC) pressure pipe and fabricated fittings with cast-iron-pipe-equivalent (CI) outside diameter (OD) dimensions and with wall-thickness dimension ratios (DRs) of 14, 18, and 25. Design considerations are provided in AWWA M23, *PVC Pipe—Design and Installation* (1980), which provides detailed information on PVC pipe covered by ANSI/AWWA C900. The manual includes chapters on general properties of PVC pipe; manufacturing, testing, and inspection; pressure capacity; design factors for external forces; hydraulics; receiving, storage, and handling; testing and maintenance; and service connections (tapping). Recommended installation guidance is provided in ANSI/AWWA C605, Standard for Underground Installation of PVC Pressure Pipe and Fittings for Water.

In addition, ANSI/AWWA C907, Standard for Polyvinyl Chloride (PVC) Pressure Fittings for Water, 4 in. Through 8 in. (100 mm Through 200 mm), provides information on injection-molded fittings for use with the PVC pipes covered by ANSI/AWWA C900.

For PVC pipe and fittings diameters greater than 12 in. (300 mm), refer to ANSI/AWWA C905, Standard for PVC Pressure Pipe and Fabricated Fittings, 14 in. Through 36 in., for Water Transmission.

I.B. *History.* This is the fourth edition of AWWA C900. In 1966, AWWA appointed Committee 8350-D to study and report on the adaptability of plastic pipe for use within the water industry. The committee presented its report on June 6, 1967, at AWWA's annual conference. The report included a recommendation that a task group be appointed to prepare standards for the use of plastic materials. The AWWA Standards Committee on Thermoplastic Pressure Pipe was established in 1968. The first, second, and third editions of this standard were approved by the AWWA Board of Directors on June 8, 1975; Jan. 25, 1981; and Jan. 29, 1989, respectively.

In June 1988, the Thermoplastic Pressure Pipe Committee was divided into two separate committees: the Polyvinyl Chloride Pressure Pipe and Fittings Standards Committee and the Polyolefin Pressure Pipe and Fittings Standards Committee. This edition of ANSI/AWWA C900 was approved by the AWWA Board of Directors on June 15, 1997.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International (NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other members of the original consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA), and the Association of State Drinking Water Administrators (ASDWA) joined later.

Wed Feb 02 02:14:13 2005

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.* Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.
3. Two standards developed under the direction of NSF, ANSI†/NSF‡ 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.
4. Other references, including AWWA standards, *Food Chemicals Codex*, *Water Chemicals Codex*,§ and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

AWWA C900-97 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues. This standard has no applicable information for this section.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser Options and Alternatives.* The following items should be covered in the purchaser's specifications:

---

*Persons in Canada, Mexico, and non-North American countries should contact the appropriate authority having jurisdiction.

†American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

‡NSF International, 3475 Plymouth Rd., Ann Arbor, MI 48106.

1. Standard used—that is, ANSI/AWWA C900, Standard for Polyvinyl Chloride (PVC) Pressure Pipe and Fabricated Fittings, 4 In. Through 12 In. (100 mm Through 300 mm), for Water Distribution, of latest revision.

2. Pipe and fabricated fittings.

a. Nominal size (for example, 4 in.).

b. Pressure class or DR (see Table 1).

c. Linear feet of each pressure class or DR for each nominal pipe size to be furnished.

d. Number, nominal size, pressure class, or DR and configuration for all fittings and couplings (for example, 20, nominal 10-in. DR 18, tees).*

3. Specifications. When desired, requirements such as the following should be specified in the purchase contract:

a. Affidavit of compliance (Sec. 6.3).

b. Standard lengths (Sec. 4.3.2.3).

c. Shipping and delivery (Sec. 6.2).

d. Standard configurations (Sec. 4.5.2.2).

4. Plant inspection. If plant inspections are desired, provisions must be specified in the purchase contract (Sec. 5.3):

a. Production notice. The manufacturer should be required to give adequate advance notice of when and where production of ordered materials will start.

b. Inspection aids. The manufacturer should be required to make available to the purchaser, without charge, such tools and assistance as are necessary for the inspection and handling of materials.

c. Inspection limitations. To exclude inspection of proprietary manufacturing processes, the manufacturer should be required to give advance notice to the purchaser.

III.B. *Modification to Standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. Major changes made to the standard in this edition include the following:

1. The format has been changed to AWWA standard style.

2. The acceptance clause (Sec. I.C) and the definitions of parties (Sec. 3) have been revised to approved wording.

3. Fabricated PVC fittings have been added.

4. Appendix A, Design Requirements and Criteria for Polyvinyl Chloride (PVC) Pipe for Water Distribution, has been removed (see AWWA M23).

V. Comments. If you have any comments or questions about this standard, please call the AWWA Standards and Materials Development Department, (303) 794-7711 ext. 6283, FAX (303) 795-1440, or write to the department at 6666 W. Quincy Ave., Denver, CO 80235.

*NOTE: Purchaser's specifications may allow or require the use of fittings other than those described in ANSI/AWWA C900. Some examples of compatible fittings include those covered in AWWA Standards C907, C153, and C110.

American Water Works Association

ANSI/AWWA C900-97
(Revision of ANSI/AWWA C900-89)

AWWA STANDARD FOR

POLYVINYL CHLORIDE (PVC) PRESSURE PIPE AND FABRICATED FITTINGS, 4 IN. THROUGH 12 IN. (100 mm THROUGH 300 mm), FOR WATER DISTRIBUTION

SECTION 1: GENERAL

Sec. 1.1 Scope

This standard covers 4-in. through 12-in. (100-mm through 300-mm) polyvinyl chloride (PVC) pressure pipe and fabricated fittings with cast-iron-pipe-equivalent (CI) outside diameter (OD) dimensions and with wall-thickness-dimension ratios (DRs) 14, 18, and 25.

Sec. 1.2 Purpose

The purpose of this standard is to provide direction and guidance for manufacturing, testing, selecting, and purchasing PVC pressure pipe and fabricated fittings for underground water distribution systems.

Sec. 1.3 Application

This standard can be referenced in specifications for purchasing and receiving PVC pressure pipe and fabricated fittings, 4 in. through 12 in. (100 mm through 300 mm), for water distribution. This standard can be used as a guide for manufacturing and testing this type of pressure pipe. The stipulations of this standard apply when this document has been referenced and then only to PVC pressure pipe and fabricated fittings, 4 in. through 12 in. (100 mm through 300 mm).

SECTION 2: REFERENCES

This standard references the following documents. In their latest editions, they form a part of this standard to the extent specified within the standard. In any case of conflict, the requirements of this standard shall prevail.

ANSI*/ASTM† D1784—Standard Specification for Rigid Poly(Vinyl Chloride) (PVC) Compounds and Chlorinated Poly(Vinyl Chloride) (CPVC) Compounds.

ASTM D1598—Standard Test Method for Time-to-Failure of Plastic Pipe Under Constant Internal Pressure.

ASTM D1599—Standard Test Method for Short-Time Hydraulic Failure Pressure of Plastic Pipe, Tubing, and Fittings.

ASTM D2122—Standard Test Method for Determining Dimensions of Thermoplastic Pipe and Fittings.

ASTM D2152—Standard Test Method for Adequacy of Fusion of Extruded Poly(Vinyl Chloride) (PVC) Pipe and Molded Fittings by Acetone Immersion.

ASTM D2241—Standard Specification for Poly(Vinyl Chloride) (PVC) Pressure-Rated Pipe (SDR Series).

ASTM D2412—Standard Test Method for Determination of External Loading Characteristics of Plastic Pipe by Parallel-Plate Loading.

ASTM D2564—Standard Specification for Solvent Cements for Poly(Vinyl Chloride) (PVC) Plastic Piping Systems.

ASTM D2837—Standard Test Method for Obtaining Hydrostatic Design Basis for Thermoplastic Pipe Materials.

ASTM D2855—Standard Practice for Making Solvent-Cemented Joints with Poly(Vinyl Chloride) (PVC) Pipe and Fittings.

ASTM D3139—Standard Specification for Joints for Plastic Pressure Pipes Using Flexible Elastomeric Seals.

ASTM F477—Standard Specification for Elastomeric Seals (Gaskets) for Joining Plastic Pipe.

NSF‡ 61—Drinking Water System Components—Health Effects.

PPI§ TR-3—Policies and Procedures for Developing Recommended Hydrostatic Design Stresses for Thermoplastic Pipe Materials.

SECTION 3: DEFINITIONS

The following definitions shall apply in this standard:

1. *Dimension ratio (DR):* For pipe covered by this standard, the DR is determined by dividing the average OD of the pipe by its minimum wall thickness and rounding off the dimensionless quotient, when necessary, to the nearest whole number.

*American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

†American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959.

‡NSF International, 3475 Plymouth Rd., Ann Arbor, MI 48106.

§Plastics Pipe Institute, 1275 K St. N.W., Ste. 400, Washington, DC 20005.

Copyright by the American Water Works Association
Wed Feb 02 02:14:15 2005

2. *Fabricated PVC fitting:* Fabricated fittings comprise single or multiple segments of PVC pipe cut in wedge shapes, or otherwise prepared to accept leg insertions, and joined under factory-controlled conditions to form an essentially homogeneous structure. Reinforcement may be applied and permanently bonded to the outside surfaces of the fitting.

3. *Hydrostatic design basis (HDB):* The long-term, hydrostatic-strength (hoop stress) rating of a specific plastic pipe material as determined by hydrostatic tests, evaluation, and categorization procedures in accordance with ASTM D2837. This standard requires the use of PVC compounds that qualify for an HDB rating of 4,000 psi (27.58 MPa).

4. *Manufacturer:* The party that manufactures, fabricates, or produces materials or products.

5. *Pressure class (PC):* A pipe's designated design capacity, in pounds per square inch (psi), that corresponds with its recommended safe sustained operating pressure. Pressure class designations include an allowance for pressure surges above the maximum sustained operating pressure caused by instantaneous velocity changes of 2 ft/s (0.61 m/s). Pressure class designations are based on long-term, pressure testing at 73.4°F (23°C).

6. *Purchaser:* The person, company, or organization that purchases any materials or work to be performed.

7. *Sample/specimen:* The word "sample" is only used to describe a piece or quantity of bulk material that has been selected by some sampling process. Pieces or quantities taken from production for testing are called "specimens." To describe the piece on which a test is made, "specimen" or "test specimen" is used.

8. *Supplier:* The party that supplies material or services. A supplier may or may not be the manufacturer.

SECTION 4: REQUIREMENTS

Sec. 4.1 Permeation

The selection of materials is critical for water service and distribution pipe in locations where there is likelihood the pipe will be exposed to significant concentrations of pollutants comprised of low molecular weight petroleum products or organic solvents or their vapors. Research has documented that pipe materials such as polyethylene, polybutylene, polyvinyl chloride, and asbestos cement, and elastomers, such as used in jointing gaskets and packing glands, may be subject to permeation by lower molecular weight organic solvents or petroleum products. If a water pipe must pass through such a contaminated area or an area subject to contamination, consult with the manufacturer regarding permeation of pipe walls, jointing materials, and so forth, *before* selecting materials for use in that area.

Sec. 4.2 Materials

4.2.1 *Pipes, couplings, and fabricated fittings.* PVC pipe, couplings, and fabricated fittings shall be made from virgin PVC resin that has been compounded to provide physical and chemical properties that equal or exceed cell class 12454-B as defined in ASTM D1784, and shall qualify for a hydrostatic design basis (HDB) of 4,000 psi (27.58 MPa) at 73.4°F (23°C) per the requirements of PPI TR-3.

Copyright by the American Water Works Association
Wed Feb 02 02:14:15 2005

4.2.2 *Rework materials.* Clean rework materials generated from the manufacturer's own pipe or fitting production may be used by the same manufacturer for the same purposes provided that the following criteria are present:

a. They comply with all applicable requirements of ASTM D1784 for cell class 12454-B and this standard.

b. The finished products are equal in quality to products made from virgin PVC compounds.

4.2.3 *Certification for potable-water service.* PVC compounds and products shall be tested for chemical extractants and certified as suitable for potable-water distribution service by an accredited testing agency acceptable to the purchaser, in accordance with requirements that are no less restrictive than the applicable requirements specified in NSF 61.

4.2.4 *Gaskets and lubricants.* Gaskets and lubricants intended for use with PVC pipe, couplings, and fabricated fittings shall be made from materials that are compatible with the pipe and with each other when used together. Gaskets and lubricants shall not adversely affect the potable quality of the water that is to be transported (see foreword, Sec. I.C).

4.2.4.1 Elastomeric gaskets. One gasket shall be furnished with each bell end of every pipe, fitting, and coupling. Elastomeric gaskets shall meet the requirements of ASTM F477 for high-head (50 ft of head or higher) applications.

4.2.5 *Fabricated fitting overwrapped reinforcement.* Optional reinforcement, either PVC or non-PVC, may be applied by the manufacturer to meet the requirements of this standard.

4.2.5.1 Resin. All resins used shall be a commercial grade of unsaturated polyester resin or epoxy resin.

4.2.5.2 Glass. All glass reinforcing materials shall be commercial "E" type glass in the form of mat, continuous roving or roving fabric, or a combination of these, having a coupling agent that bonds the glass reinforcement and the resin.

Sec. 4.3 Pipe Requirements

4.3.1 *Workmanship.* When manufactured, pipe shall be homogeneous throughout; free from voids, cracks, inclusions, and other defects; and as uniform as commercially practical in color, density, and other physical properties. Pipe surfaces shall be free from nicks and significant scratches.* The joining surfaces of pipe spigots and integral-bell and sleeve-reinforced bell sockets shall be free of imperfections that might cause leakage at joints.

4.3.2 *Dimensions.*

4.3.2.1 Pipe barrel. The dimensions and tolerances of the pipe barrel shall conform with the applicable requirements listed in Table 1 when measured as specified in ASTM D2122.

4.3.2.2 Elastomeric-gasket bell ends. The dimensions of the integral bell ends shall meet one of the following requirements when measured according to ASTM D2122.

a. The bell wall thickness at any point shall conform to the dimension ratio of the pipe except in the annular gasket ring groove and bell entry lip portions where the wall shall be at least the minimum thickness of the pipe barrel (Table 1).

*Scratches that extend 10 percent or more into the pipe wall shall be considered significant.

*Hydrostatic design stress (HDS) = 1,600 psi.

b. Designs not meeting the requirements of 4.3.2.2(a) shall be tested to verify that the joint assemblies qualify for a hydrostatic design basis (HDB) category of 4,000 psi (27.58 MPa) when tested in accordance with ASTM D2837 as modified in ASTM D3139.

4.3.2.3 Standard lengths. Pipe shall be furnished in standard laying lengths of 20 ft ± 1 in. (6.1 m ± 25 mm), unless otherwise agreed on at time of purchase.

4.3.3 *Physical properties.*

4.3.3.1 Sustained pressure. The pipe or fabricated fitting shall not fail, balloon, burst, or weep, as defined in ASTM D1598, at the applicable sustained pressure listed in Table 2 when six specimens are tested for 1,000 h as specified in ASTM D2241. Either free-end or restrained-end closures that are free of leaks at maximum pressure shall be used.

4.3.3.2 Burst pressure. The quick-burst strength of pipe, including any integral bell end, shall meet the applicable minimum pressure requirement listed in Table 3 when tested in accordance with the specimen and sample sizes, conditioning, and procedural requirements listed in ASTM D1599. At least three of the five test specimens shall have a portion of the required markings located at least one pipe diameter away from an end closure. For bell-end pipe, the bell shall be included as a part of at least two test specimens. The ability to attain hydrostatic pressure equal to or greater than the values in Table 3 within 60–70 seconds shall indicate passing this test requirement.

4.3.3.3 Hydrostatic integrity. The pipe, including any integral bell end or affixed coupling, shall not fail, balloon, burst, or weep when subjected to an internal

Table 2 Sustained-pressure requirements

	Pressure Class		Pressure Required for Test With Water at 73.4°F (23°C)	
DR	*psi*	*(kPa)*	*psi*	*(kPa)*
14	200	1,380	650	(4,480)
18	150	950	500	(3,450)
25	100	690	350	(2,410)

NOTE: Test pressures were derived using a pipe fiber stress of 4,200 psi (29,000 kPa).

Table 3 Burst-pressure requirements

	Pressure Class		Pressure Required for Test With Water at 73.4°F (23°C)	
DR	*psi*	*(kPa)*	*psi*	*(kPa)*
14	200	1,380	985	(6,790)
18	150	950	755	(5,210)
25	100	690	535	(3,690)

NOTE: Test pressures were derived using a pipe fiber stress of 6,400 psi (44,175 kPa).

pressure equal to four times its designated pressure class, as listed in Table 1, for a minimum dwell of 5 seconds. The pipe shall attain ambient temperature before testing. When the ambient temperature is higher than 77°F (25°C), the test pressure shall be reduced by applying the appropriate temperature coefficient from Table 4.

4.3.3.4 Flattening. Three specimens of pipe, a minimum of 2 in. (50 mm) long, shall be flattened between parallel plates in a suitable press until the distance between the plates is 40 percent of the OD of the pipe. The three specimens shall be oriented in accordance with the section entitled "Procedure" of ASTM D2412; except, if no minimum wall thickness has been identified, a spider line shall be used as the base line. The rate of flattening shall be uniform and such that the compression is completed within 2 to 5 min. The applied load shall then be removed and the specimen examined. There shall be no evidence of splitting, cracking, or breaking.

4.3.3.5 Extrusion quality. The pipe shall not fail when tested by the acetone-immersion method as specified in ASTM D2152.

Sec. 4.4 Machined Coupling Requirements

4.4.1 *Workmanship.* The body and joining surfaces of couplings machined from extruded pipe shall conform with the same requirements as specified for pipe in Sec. 4.3.

4.4.2 *Dimensions.* The computed dimension ratio of gasketed PVC couplings machined from extruded pipe shall not be greater than the DR of the pipe, except in the annular gasket space and coupling entry where the wall thickness shall be at least the minimum wall thickness of the pipe (Table 1).

4.4.3 *Burst pressure.* The quick-burst strength of couplings shall not be less than the minimum burst pressure specified for the pipe with which the couplings are designed to be used when tested as specified in Sec. 4.3.3.2.

Copyright by the American Water Works Association
Wed Feb 02 02:14:17 2005

Table 4 Temperature coefficients

Pipe Temperature		Pressure Rating Reduction Coefficient
°F	(°C)	
80	(27)	0.88
90	(32)	0.75
100	(38)	0.62
110	(43)	0.50
120	(49)	0.40
130	(54)	0.30
140	(60)	0.22

4.4.4 *Hydrostatic integrity.* Couplings shall not fail, balloon, burst, or weep when subjected to an internal pressure equal to four times the designated pressure class of the pipe with which it is designed to be used. The coupling shall attain ambient temperature before testing. When the ambient temperature is higher than 77°F (25°C), the test pressure shall be reduced using Table 4.

4.4.5 *Standard quantities.* If elastomeric-gasketed couplings are to be used as the primary pipe-joining method, one such coupling of a corresponding size and pressure class shall be furnished with each length of plain-end pipe.

Sec. 4.5 Fabricated Fitting Requirements

4.5.1 *Workmanship.* Fittings shall be fabricated from PVC pipe meeting the requirements of this standard. The component pipe segments and the bonds between them shall be free from voids, cracks, inclusions, and other defects. The joining surfaces of spigots and bells shall be free from imperfections that could cause leaks. When component segments are joined using solvent cement, the procedure shall conform with the standard practice for making pressure joints in ASTM D2855.

4.5.2 *Dimensions.*

4.5.2.1 Fitting barrel. All edge-joined segments of a fabricated fitting shall have the same dimension ratio.

4.5.2.2 Standard configurations. Standard configurations shall include customary angles for branch connections or bends. Non-standard angles of branch connections or bends may be specified. Leg lengths shall be the minimum practical for the method of fabrication, unless otherwise specified.

4.5.2.3 Reinforcement of solvent cement joints. Fitting segments that are joined by solvent cementing shall be designed on the basis of a maximum lap shear strength of the solvent cement joint of 900 psi (6.2 MPa). Overwrapped reinforcement shall not be considered in design of the solvent cement joint.

4.5.3 *Segment joint quality.*

4.5.3.1 Edge-joined fabricated fitting segments. There shall be no evidence of arcing or sparks from the probe tip when butt-fused or thermally welded joints are subjected to the following test.

A grounding medium compatible with PVC pipe shall be applied to the inside or outside of each butt-fused or thermally welded segment joint before any reinforcement is applied. The grounding medium in the prepared resin (polyester or epoxy) is graphite, which is added to the resin in the proportion of 20 percent by volume. The

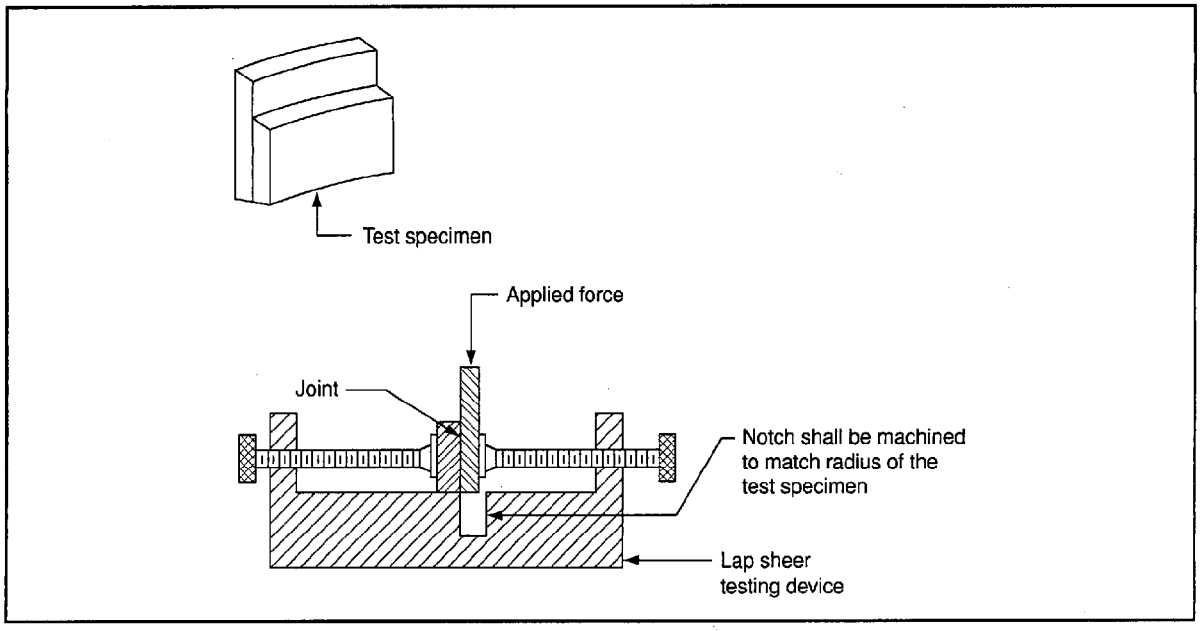

Figure 1 Lap shear test

grounding medium shall cover the joint with a strip not less than 1 in. (25 mm) wide. A suitable probe, energized with 25,000 V, shall be swept along the joint line approximately 0.1 in. (3 mm) away from the PVC surface of the joined segments on the side opposite to the grounding medium. Any discontinuity in the segment joint is indicated by the jump of an arc (sparking) from the probe tip and shall be cause for rejection of the fitting.

4.5.3.2 Solvent cemented bond quality. Specimens for lap shear testing shall be prepared in accordance with the requirements of ASTM D2564, except as modified in this standard. The test specimens shall be obtained from a sample solvent cemented joint produced by solvent cementing component pipe segments identical to those to be used to fabricate fittings. After at least a 72-h solvent cement curing time at 73.4 ± 3.6°F (23 ± 2°C), three specimens shall be tested per segment joint. Each specimen shall be a section of the segment joint measuring approximately 1 in. × 2 in. (25 mm × 50 mm) and shall not include any overwrapping reinforcement. A portion of each test specimen shall be machined off as needed to obtain a specimen similar to that shown in Figure 1. After placing the specimen in a testing device similar to that shown in Figure 1, apply the force at a shear speed of 0.05 in. (1.25 mm)/min. The minimum average lap shear strength of the three specimens shall be 900 psi (6.2 MPa).

NOTE: Where mechanical joint restraint devices are used to control thrust movements of fabricated fittings, consult with the fittings manufacturer to determine the tensile thrust limitations for the specific sizes, configurations, and pressure classes specified.

4.5.4 *Pressure test.* The fabricated fitting shall not fail, balloon, burst, or weep when subjected to an internal pressure equal to four times its designated pressure class for a minimum of 1 h.

Copyright by the American Water Works Association
Wed Feb 02 02:14:18 2005

Sec. 4.6 Joint Requirements

Bell-end pipe, couplings, and fittings designed for making PVC joints using elastomeric gaskets to effect the pressure seal shall be tested as assembled joints and shall meet the laboratory performance requirements specified in ASTM D3139. (These are qualifying test requirements to determine proper design and performance of specimen joints.)

Sec. 4.7 Pressure-Class Designations

4.7.1 *Pipe and couplings.* Pressure-classes (PCs) shall be as listed in Table 1 for the three different DRs covered by this standard. The pressure classes apply to maximum sustained working pressure and provide for a pressure rise above maximum working pressure caused by surge (water hammer) from an instantaneous water velocity change of 2 ft/s (0.61 m/s). Pipe pressure-classes shall be based on a safety factor of 2.5 when calculated using the following equation:

$$PC = \left[\frac{2}{DR-1} \times \frac{HDB}{F}\right] - P_s \qquad \text{(Eq 1)}$$

Where:

PC = Pressure class, in pounds per square inch (for sustained pipe temperature above 73.4°F [23°C], see Table 4)
DR = Dimension ratio (Sec. 3)
HDB = Hydrostatic design basis, which for this standard shall be 4,000 psi (27.58 MPa)
F = Safety factor, which for this standard shall be 2.5
P_s = Surge pressure allowance, in pounds per square inch, based on an instantaneous velocity change of 2 ft/s (0.61 m/s). The pressure rise for a 2 ft/s (0.61 m/s) abrupt velocity change is 40, 35, and 30 psi (280, 240, and 200 kPa) for DRs 14, 18, and 25, respectively.

4.7.2 *Fabricated fittings.* Fabricated PVC fittings meeting the requirements of this standard shall have the pressure class designations listed in Table 1 that are equivalent to the dimension ratio of the pipe used in their fabrication. The determination of pressure classes and safety factors for fabricated fittings shall follow the method given in Sec. 4.7.1 for pipe meeting the requirements of this standard, ignoring the effect of any overwrapped reinforcement.

SECTION 5: VERIFICATION

Sec. 5.1 Quality-Control and Qualification Test Requirements

The manufacturer shall take adequate measures in the production of extruded PVC pipe, couplings, and fabricated fittings to assure product compliance with the requirements of this standard. The pipe, couplings, and fabricated fittings shall be tested at 73.4 ± 3.6°F (23 ± 2°C), unless otherwise specified, in accordance with the requirements of Sec. 4.3, 4.4, 4.5, and 4.6 at intervals as required in this standard.

5.1.1 *Pipe dimensions.* The dimensions of pipe produced from each extrusion outlet, and the bell or sleeve-reinforced bell of pipe with such ends, shall be measured

Copyright by the American Water Works Association
Wed Feb 02 02:14:18 2005

in accordance with Sec. 4.3.2 at the beginning of production of each specific material and each size. Thereafter, one specimen from each extrusion outlet shall be measured each hour.

5.1.2 *Coupling dimensions.* The dimensions of machined couplings shall be measured in accordance with Sec. 4.4.2 at the beginning of production of each specific material and each size. Thereafter, one specimen shall be measured each hour.

5.1.3 *Sustained pressure.* At the beginning of production and semiannually thereafter, specimens of 4-in. (100-mm) or 6-in. (150-mm) pipe and of 8-in. (200-mm) or larger pipe that are made from each PVC pressure pipe commercial compound (i.e., material) shall be tested in accordance with Sec. 4.3.3.1. (These tests are for qualification of the compound and the extrusion process—not for quality control of the product.)

5.1.4 *Pipe burst strength.* The quick-burst strength of pipe produced from each extrusion outlet shall be tested in accordance with Sec. 4.3.3.2 at the beginning of production of each specific material and each size. Thereafter, one specimen from each extrusion outlet shall be tested every 24 h.

5.1.5 *Coupling burst strength.* The quick-burst strength of machined couplings shall be tested in accordance with Sec. 4.4.3 at the beginning of production of each specific material and each size. Thereafter, one specimen shall be tested every 8 h.

5.1.6 *Flattening capability.* The flattening capability of pipe shall be tested in accordance with Sec. 4.3.3.4 at the beginning of production from each extrusion outlet for each specific material and each size. Thereafter, one specimen from each extrusion outlet shall be tested every 8 h.

5.1.7 *Extrusion quality.* The pipe produced from each extrusion outlet shall be tested in accordance with Sec. 4.3.3.5 at the beginning of production of each specific material and each size. Thereafter, one specimen from each extrusion outlet shall be tested every 8 h.

5.1.8 *Fitting segment fusion.* Each fitting manufactured using the butt-fusion or thermal welding method of segment joining shall be tested in accordance with Sec. 4.5.3.1.

5.1.9 *Fitting segment solvent cemented bond quality.* Where solvent cementing is used to join fitting segments, the quality of the bond shall be tested in accordance with Sec. 4.5.3.2 at the startup of a production run. Thereafter, the quality of the bond shall be tested at least once every 15 calendar days of production or 200 fittings, whichever is more frequent.

5.1.10 *Fabricated fitting pressure tests.*

5.1.10.1 Qualification pressure test. For a specific production process and whenever the production process is changed, a representative fabricated fitting specimen shall be subjected to a sustained pressure test in accordance with Sec. 4.3.3.1. A representative specimen shall be the most critically stressed fitting configuration. (NOTE: Critical stresses generally occur where fitting segments are joined together.)

5.1.10.2 Quality control pressure test. At the beginning of production and at least once every 15 calendar days of production or 200 fittings, whichever is more frequent, a fabricated fitting specimen shall be tested in accordance with Sec. 4.5.4.

5.1.11 *Provision for test failure.* When any PVC product fails to meet a requirement specified in this standard or in a referenced standard, additional tests shall be performed to determine which products are acceptable of those produced

Copyright by the American Water Works Association
Wed Feb 02 02:14:18 2005

STD.AWWA C900-ENGL 1997 ■ 0783350 0505575 272 ■

since the last favorable test. Products that fail to meet any requirement shall be rejected.

5.1.12 *Hydrostatic proof test for pipe.* Each standard and random length of pipe shall be proof tested in accordance with Sec. 4.3.3.3.

5.1.13 *Hydrostatic proof test for machined couplings.* Each separate machined coupling shall be proof tested in accordance with Sec. 4.4.4.

5.1.14 *Additional test requirements.* The purchaser or supplier may allow the manufacturer to conduct hydrostatic proof tests for pipes or couplings at test frequencies other than required in Sec. 5.1.12 and 5.1.13.

Sec. 5.2 Quality-Control Records

The manufacturer shall maintain, for a period of not less than two years, a record of all quality-control tests and shall, if requested, submit the pertinent record to the purchaser.

Sec. 5.3 Plant Inspection

5.3.1 *Plant access.* The purchaser shall have free access to those parts of a manufacturer's plant that are necessary to assure that products comply with all requirements.

5.3.2 *Responsibility for compliance.* Plant inspection by the purchaser or the omission of such inspections shall not relieve the manufacturer of the responsibility to furnish materials complying with the applicable requirements of this standard.

SECTION 6: DELIVERY

Sec. 6.1 Marking

6.1.1 *General.* Pipe, couplings, and fittings shall bear identification markings that will remain legible during normal handling, storage, and installation. The markings shall be applied in a manner that will not reduce the strength of any product covered by this standard.

6.1.2 *Pipe.* Marking on pipe shall include the following and shall be applied at intervals of not more than 5 ft (1.5 m):

a. Nominal size (for example, 4 in.).
b. PVC.
c. Dimension ratio (for example, DR 25).
d. AWWA pressure class (for example, PC 100).
e. AWWA designation number for this standard (ANSI/AWWA C900-97).
f. Manufacturer's name or trademark and production-record code.
g. Seal (mark) of the testing agency verifying the suitability of the pipe material for potable-water service (Sec. 4.2.3).

6.1.3 *Couplings and fabricated fittings.* Marking on couplings and fabricated fittings shall include the following:

a. Nominal size and deflection angle if applicable (for example, 8 in. × 4 in. or 8-in. 45°).
b. PVC.
c. AWWA pressure class (for example, PC 150).
d. AWWA designation number for this standard (ANSI/AWWA C900-97).
e. Manufacturer's name or trademark.

Copyright by the American Water Works Association
Wed Feb 02 02:14:19 2005

f. Seal (mark) of the testing agency verifying the suitability of the coupling or fitting for potable-water service (Sec. 4.2.3).

Sec. 6.2 Shipping and Delivery

6.2.1 *Shipping.* All pipe, couplings, and fabricated fittings shall, unless otherwise specified by the purchaser, be prepared for standard commercial shipment.

6.2.2 *Delivery.* Pipe, couplings, and fabricated fittings that do not comply with the applicable requirements of this standard or that are damaged when received shall be replaced by the manufacturer or supplier at the agreed point of delivery.

Sec. 6.3 Affidavit of Compliance

The manufacturer shall, if so specified by the purchaser, furnish an affidavit that all delivered materials comply with the requirements of this standard and of the purchaser.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

Foreword

This foreword is for information only and is not part of ANSI/AWWA C950.

I. Introduction

I.A. *Background.* This standard provides direction and guidance in selecting and purchasing fiberglass pipe for use as pressure pipe in water distribution (including services) and transmission systems for both aboveground and belowground installations.

This standard covers 1-in. through 144-in. (25-mm through 3,600-mm) diameter pressure pipes. The primary materials used are thermosetting polyester or epoxy resins, glass-fiber reinforcement, and, if used, aggregate. There are five pressure classes, which range from 50 psi through 250 psi (345 kPa through 1,724 kPa), in 50-psi (345-kPa) increments. Stiffness classes covered are 9, 18, 36, and 72 psi (62, 124, 248, and 496 kPa). This standard may be used to the extent applicable for other sizes, pressure classes, and stiffness classes.

I.B. *History.* In June 1971, the AWWA Engineering and Construction Technical and Professional Committee organized the Reinforced Plastics Committee to evaluate both the use of reinforced plastics in the water-supply industry and the need for appropriate AWWA standards. The Reinforced Plastics Committee found sufficient use and interest to support a recommendation that a standard be developed for fiberglass pipe. The Standards Council authorized the formation of the Standards Committee on Thermosetting Fiberglass Reinforced Plastic Pipe in October 1972, and committee organization was completed in December 1974. The first edition of the standard was approved by the AWWA Board of Directors on Jan. 25, 1981. The second edition was approved on June 23, 1988.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International (NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other members of the original consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA) and the Association of State Drinking Water Administrators (ASDWA) joined later.

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.* Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.

*Persons in Canada, Mexico, and non-North American countries should contact the appropriate authority having jurisdiction.

Copyright by the American Water Works Association
Wed Feb 02 02:14:55 2005

3. Two standards developed under the direction of NSF, ANSI*/NSF† 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.

4. Other references, including AWWA standards, *Food Chemicals Codex*, *Water Chemicals Codex*,‡ and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

ANSI/AWWA C950-95 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements, including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues

II.A. *Nominal Metric Pipe Sizes, Dimensions, and Tolerances.* Nominal metric pipe sizes, dimensions, and tolerances were obtained from International Organization for Standardization (ISO) specification 7370, Glass Fibre Reinforced Thermosetting Plastics (GRP) Pipes and Fittings—Nominal Diameters, Specified Diameters and Standard Lengths, and proposed addenda to that document.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser Options and Alternatives.* The following items should be covered in the purchaser's specifications:

1. Standard used—that is, ANSI/AWWA C950, Standard for Fiberglass Pressure Pipe, of latest revision.
2. Pipe diameter size and series (Sec. 4.5.1).
3. Pressure classes (Sec. 4.6).
4. Stiffness classes (Sec. 4.7).
5. Specific service and installation considerations.
6. Lineal feet of each pressure and stiffness class and size.

7. Whether plant inspection is required (Sec. 5.1.1).

The purchaser may also specify the following:

1. Cell classification (Sec. 4.3).
2. Standard laying lengths (Sec. 4.5.2).
3. Joint configuration (Sec. 4.9).
4. Line layout showing pressure zones, including applicable design and transient pressures within zones and points of change between zones.

III.B. *Manufacturer Options and Alternatives.* The following items should be provided in the manufacturer's specifications:

1. Cell classification (Sec. 4.3).
2. Stiffness class (Sec. 4.7).
3. Joint details (Sec. 4.9).
4. Nominal wall thickness.
5. Weight.
6. Total quantity of jointing materials and field allowances.

When requested by the purchaser, it is understood that the manufacturer also will supply the following:

1. Special design calculations.
2. Special lengths (Sec. 4.5.2).
3. Special preparations needed for shipment (Sec. 6.2).
4. Affidavit of compliance (Sec. 6.3).

III.C. *Modification to Standard.* Any modifications to the provisions, definitions, or terminology in this standard must be provided in the purchaser's or manufacturer's specifications.

IV. Major Revisions. Major changes made to the standard in this revision include the following:

1. Tables 1, 3, 4, 7, and 8 through 13 were metricized.
2. The format has been changed to AWWA standard style.
3. The acceptance clause (Sec. I.C.) and the definitions of parties (Sec. 3) have been revised to approved wording.
4. Section 4.9, Joint Types and Requirements, was revised.
5. The information in Appendixes A through D on design, testing, installation, shipping, handling, and storage has been removed from the standard and included in AWWA Manual M45, Fiberglass Pipe Design.

V. Comments. If you have any comments or questions about this standard, please call the AWWA Standards and Materials Development Department, (303) 794-7711 ext. 6283, FAX (303) 795-1440, or write to the department at 6666 W. Quincy Ave., Denver, CO 80235.

ANSI/AWWA C950-95
(Revision of ANSI/AWWA C950-88)

AWWA STANDARD FOR

FIBERGLASS PRESSURE PIPE

SECTION 1: GENERAL

Sec. 1.1 Scope

This standard covers the fabrication and the testing of nominal 1-in. through 144-in. (25-mm through 3,600-mm) fiberglass pipe and joining systems for use in both aboveground and belowground water systems. Service and distribution piping systems and transmission piping systems are included.

Both glass-fiber-reinforced thermosetting-resin pipe (RTRP) and glass-fiber-reinforced plastic-mortar pipe (RPMP) are fiberglass pipes. Epoxy-resin and polyester-resin systems are covered, and commercial-grade E-type glass is specified as the glass-fiber reinforcement material in the pipe wall. Liner materials incorporated include thermosetting or thermoplastic resin, reinforced or unreinforced, with or without fillers. Pressure classes covered are 50, 100, 150, 200, and 250 psig (345, 689, 1,034, 1,379, and 1,724 kPa). Stiffness classes covered are 9, 18, 36, and 72 psi (62, 124, 248, and 496 kPa). This standard may be used to the extent applicable for other diameters, pressure classes, and stiffness classes. For information on design, hydraulics, and installation, refer to AWWA Manual M45, *Fiberglass Pipe Design.*

Sec. 1.2 Purpose

The main purpose of this standard is to provide the minimum requirements for fiberglass pressure pipe, including design, fabrication, and testing requirements.

Sec. 1.3 Application

This standard can be referenced in specifications for purchasing and receiving fiberglass pressure pipe. This standard can be used as a guide for manufacturing this type of fiberglass pressure pipe. The stipulations of this standard apply when this document has been referenced and then only to fiberglass pressure pipe.

Copyright by the American Water Works Association

SECTION 2: REFERENCES

This standard references the following documents. In their latest editions, these documents form a part of this standard to the extent specified within the standard. In case of conflict, the requirements of this standard shall prevail.

ASTM* C33—Standard Specification for Concrete Aggregates.

ASTM D638—Standard Test Method for Tensile Properties of Plastics.

ASTM D695—Standard Test Method for Compressive Properties of Rigid Plastics.

ASTM D1599—Standard Test Method for Short-Time Hydraulic Failure Pressure of Plastic Pipe, Tubing, and Fittings.

ASTM D2105—Standard Test Method for Longitudinal Tensile Properties of 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe and Tube.

ASTM D2290—Standard Test Method for Apparent Tensile Strength of Ring or Tubular Plastics and Reinforced Plastics by Split Disk Method.

ASTM D2412—Standard Test Method for Determination of External Loading Characteristics of Plastic Pipe by Parallel-Plate Loading.

ASTM D2992—Standard Practice for Obtaining Hydrostatic or Pressure Design Basis for 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe and Fittings.

ASTM D3517—Standard Specification for 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pressure Pipe.

ASTM D3567—Standard Practice for Determining Dimensions of 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe and Fittings.

ASTM D3681—Standard Test Method for Chemical Resistance of 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe in a Deflected Condition.

ASTM D4161—Standard Specification for 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe Joints Using Flexible Elastomeric Seals.

ASTM D5365—Standard Test Method for Long-Term Ring-Bending Strain of 'Fiberglass' (Glass-Fiber-Reinforced Thermosetting-Resin) Pipe.

ASTM F477—Standard Specification for Elastomeric Seals (Gaskets) for Joining Plastic Pipe.

SECTION 3: DEFINITIONS

The following definitions shall apply in this standard:

1. *Aggregate:* Siliceous sand conforming to ASTM C33, except that the requirements for gradation need not apply.

2. *Centrifugal casting:* A process used to manufacture tubular goods by applying resin and reinforcement to the inside of a mold that is rotated and heated, subsequently polymerizing the resin system. The outside diameter (OD) of the finished pipe is determined by the inside diameter (ID) of the mold tube. The ID of the finished pipe is determined by the amount of material introduced into the mold.

*American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959.

Copyright by the American Water Works Association
Wed Feb 02 02:14:56 2005

Other materials that will not adversely affect the laminate performance may be introduced in the process during manufacture of the pipe.

3. *Constructor:* The party that furnishes the work and materials for placement or installation.

4. *Epoxy resin (thermosetting):* A polymer containing two or more three-membered rings, each consisting of one oxygen and two carbon atoms. The polymer is cured by cross-linking with an amine or anhydride hardener, with or without heat, catalyst, or both.

5. *Fiberglass pipe:* A tubular product containing glass-fiber reinforcements embedded in or surrounded by cured thermosetting resin. The composite structure may contain aggregate, granular or platelet fillers, thixotropic agents, and pigments or dyes. Thermoplastic or thermosetting liners or coatings may be included.

6. *Filament winding:* A process used to manufacture tubular goods by winding continuous glass-fiber roving or roving tape onto the outside of a mandrel or core pipe liner in a predetermined pattern under controlled tension. The roving may be saturated with liquid resin or preimpregnated with partially cured resin. Subsequent polymerization of the resin system may require application of heat. The ID of the finished pipe is fixed by the mandrel diameter or the inner diameter of the core pipe liner. The OD of the finished pipe is determined by the amount of material that is wound on the mandrel or core pipe liner. Other materials may be introduced in the process during the manufacture of the pipe, which will not adversely affect the laminate performance.

7. *Fixed end*: End of a pipe test specimen with an end closure configuration such that internal pressure produces only hoop and radial stresses in a straight pipe test specimen. Longitudinal thrust is absorbed by separate means such as tie-rods, etc.

8. *Free end*: End of a pipe test specimen with an end closure configuration such that internal pressure produces longitudinal stresses in addition to hoop and radial stresses in the pipe test specimen.

9. *Glass fabric:* A bidirectional fabric reinforcing material made by the weaving of glass-fiber yarn.

10. *Glass fibers:* A commercial grade of glass E-type filaments with binder and sizing that are compatible with the impregnating resin.

11. *Joint restraint*: A separate external device or structure that is assembled or constructed around a joint to provide restraint to longitudinal tensile forces.

12. *Liner:* A filled or unfilled thermoplastic or thermosetting resin layer, nonreinforced or reinforced, that forms the interior surface of the pipe.

13. *Manufacturer:* The party that manufactures, fabricates, or produces materials or products.

14. *Mat:* A fibrous material consisting of random-oriented, chopped, or swirled filaments loosely held together with a binder.

15. *Polyester resin (thermosetting):* An ethylenic unsaturated polymer with two or more ester groups, dissolved in a reactive diluent with vinyl unsaturation. The polymer is cured by cross-linking by means of a free-radical-initiated curing mechanism, such as peroxide catalyst and heat.

16. *Purchaser:* The person, company, or organization that purchases materials or work to be performed.

17. *Purchaser's agent:* The authorized representative of the purchaser who is entrusted with the inspection of materials and production records and the observance

Copyright by the American Water Works Association
Wed Feb 02 02:14:56 2005

of production operations and quality-control tests to ensure that the products comply with the requirements of this standard and of the purchaser.

18. *Reinforced plastic–mortar pipe (RPMP):* A fiberglass pipe with aggregate.

19. *Reinforced thermosetting-resin pipe (RTRP):* A fiberglass pipe without aggregate.

20. *Resin:* Any of a class of solid or pseudosolid organic materials, often of high molecular weight, with no definite melting point. In the broad sense, the term is used to designate any polymer that is a basic material for plastics.

21. *Restrained joint*: Pipe joint capable of withstanding internal pressure and longitudinal tensile loads.

22. *Rigid joint*: A restrained joint that is not capable of axial displacement or angular rotation.

23. *Roving:* A collection of parallel glass strands or filaments, coated with a finish or coupling agent to improve compatibility with resins, gathered without mechanical twist. Roving may be processed in a continuous or chopped form.

24. *Supplier:* The party that supplies materials or services. A supplier may or may not be the manufacturer.

25. *Stiffness class:* The nominal stiffness of a specified pipe. (The stiffness class is determined as specified in Sec. 4.7)

26. *Surface layer:* A filled or unfilled resin layer, nonreinforced or reinforced, that is applied to the exterior surface of the pipe structural wall.

27. *Surfacing mat:* A thin mat of fine fibers used primarily to produce a smooth surface on a reinforced plastic.

28. *Tape:* A unidirectional glass-fiber reinforcement consisting of rovings knitted or woven into ribbon form.

29. *Thermoplastic resin:* A plastic that can be repeatedly softened by heating and hardened by cooling and that in the softened state can be fused or shaped by flow.

30. *Thermosetting resin:* A plastic that, after having been cured by heat or other means, is substantially infusible and insoluble.

31. *Unrestrained joint*: Pipe joint capable of withstanding internal pressure, but not longitudinal tensile loads.

32. *Woven roving:* A glass-fiber fabric reinforcing material made by the weaving of glass-fiber roving.

SECTION 4: REQUIREMENTS

Sec. 4.1 Permeation

The selection of materials is critical for water service and distribution piping in locations where there is likelihood the pipe will be exposed to significant concentrations of pollutants comprised of low molecular weight petroleum products or organic solvents or their vapors. Research has documented that pipe materials, such as polyethylene, polybutylene, polyvinyl chloride, and asbestos cement, and elastomers, such as used in jointing gaskets and packing glands, may be subject to permeation by lower molecular weight organic solvents or petroleum products. If a water pipe must pass through such a contaminated area or an area subject to contamination, consult with the manufacturer regarding permeation of pipe walls, jointing materials, and so forth, **before** selecting materials for use in that area.

Copyright by the American Water Works Association
Wed Feb 02 02:14:56 2005

Sec. 4.2 Workmanship

The pipe shall be free from defects, including indentations, delaminations, bubbles, pinholes, cracks, pits, blisters, foreign inclusions, and resin-starved areas that, due to their nature, degree, or extent, detrimentally affect the strength and serviceability of the pipe. The pipe shall be as uniform as commercially practicable in color, opacity, density, and other physical properties.

Sec. 4.3 Cell Classification System

This standard covers products defined by a cell classification system and identifies the method of manufacture (type), construction and materials (grade), and liner construction (liner). The types, grades, and liners are identified in the following paragraphs. It should be noted that all possible combinations of types, grades, and liners may not be commercially available.

4.3.1 *Types.* The product type is determined by the method of manufacture, as follows:

Type I: Filament wound.

Type II: Centrifugally cast.

4.3.2 *Grades.* The product grade is determined by construction (glass-fiber-reinforced or glass-fiber-reinforced mortar) and materials (epoxy or polyester), as follows:

Grade 1: Glass-fiber-reinforced epoxy (RTRP epoxy).

Grade 2: Glass-fiber-reinforced polyester (RTRP polyester).

Grade 3: Glass-fiber-reinforced epoxy mortar (RPMP epoxy).

Grade 4: Glass-fiber-reinforced polyester mortar (RPMP polyester).

4.3.3 *Liners.* The product-liner classification is determined by whether or not a liner is used and, if used, whether it is a thermoplastic, reinforced, or nonreinforced thermoset. Classification of liners is as follows:

Liner A: No liner.

Liner B: Thermoplastic liner.

Liner C: Reinforced thermoset liner.

Liner D: Nonreinforced thermoset liner.

Sec. 4.4 Materials

The resins, reinforcement, colorants, fillers, and other materials, when combined as a composite structure, shall produce pipe products that meet the performance requirements of this standard as specified in Sec. 5.1.2.

4.4.1 *Qualification for potable water service.* The materials used to make pipe products shall contain no ingredient in an amount that has been demonstrated to migrate into water in quantities that are considered to be toxic.

4.4.2 *Certification.* Fiberglass pipe intended for use in the transport of potable water shall be evaluated and certified for such use as required by the local authority.* The seal or mark of the laboratory that evaluates the pipe should be included on the fiberglass pipe.

4.4.3 *Gaskets and lubricants.* Gaskets and lubricants shall be made from materials that (1) are compatible with the plastic materials and with each other when

*See Sec. I.C. Acceptance in the foreword for additional guidance.

Copyright by the American Water Works Association
Wed Feb 02 02:14:56 2005

used together, (2) will not support the growth of bacteria, and (3) will not adversely affect the potable qualities of water.

Sec. 4.5 Pipe Dimensions

4.5.1 *Diameters.* Pipe diameters and tolerances shall be as shown in Tables 1, 2, 3, 4, 5, and 6 when measured in accordance with ASTM D3567. These tables include dimensions for pipe based on both inside and outside diameters. In the latter case, tables are provided for steel-pipe-equivalent ODs, cast-iron-pipe-equivalent ODs, and metric ODs commonly used in international practice. As a group, the tables cover nominal pipe sizes 1 in. through 144 in. (25 mm through 3,600 mm); individual tables cover only a portion of the total range.

4.5.2 *Length.* Pipe shall be furnished in standard laying lengths as agreed on by the purchaser and manufacturer. A maximum of 15 percent of the footage of each pipe size may be furnished in random lengths. Each random length furnished shall not vary by more than 25 percent from the standard laying length specified, except for special orders.

NOTE: Common practice in the industry provides for laying lengths of 10, 20, 30, 40, or 60 ft (3, 6, 9, 12, and 18 m).

4.5.3 *Wall thickness.* The average wall thickness of the pipe shall not be less than the nominal wall thickness published in the manufacturer's literature current at the time of purchase, and the minimum wall thickness at any point shall not be less than 87.5 percent of that nominal wall thickness when measured in accordance with ASTM D3567.

Sec. 4.6 Pressure Classes

The standard pressure classes for pipe shall be 50, 100, 150, 200, and 250 psig (345, 689, 1,034, 1,379, and 1,724 kPa). The pressure classes refer to the maximum sustained working pressure. They are determined in accordance with Sec. 4.6.2 using a design factor of 1.8. The pressure classes may have to be changed for pipes conveying water at elevated temperatures (in accordance with the manufacturer's recommendations) and whenever there is a need to provide more allowance for surge pressure.

For pipe subjected to circumferential bending, the effect of such bending on the hydrostatic design pressure class of the pipe must be considered.

4.6.1 *Thermoplastic lined pipe.* The pressure classes for thermoplastic lined pipe are based on a water temperature of 73.4°F (23°C). The classes shall be reduced for use at temperatures greater than 73.4°F (23°C). The temperature-derating service factors shall be supplied by the pipe manufacturer.

4.6.2 *Long-term hydrostatic design pressure.* The pressure classes shall be based on long-term hydrostatic-design-pressure data extrapolated to 50 years, using procedure B of ASTM D2992 or, alternately, with the procedure specified in Annex A.1 of ASTM D3517. Procedure A data from ASTM D2992 may be used in place of procedure B data at the option of the manufacturer. End fixtures used during testing shall be representative of the product use as follows:

Service	Test End Fixture
Restrained joints	Free ends
Unrestrained joints	Fixed ends

*Values taken from international practice; values in parentheses indicate nonpreferred diameters.

Sec. 4.7 Stiffness Classes

The standard stiffness classes shall be 9, 18, 36, and 72 psi (62, 124, 248, and 496 kPa) and shall be determined in accordance with Sec. 5.1.2.2.

Copyright by the American Water Works Association
Wed Feb 02 02:14:57 2005

Sec. 4.8 Long-Term Ring-Bending Strain

4.8.1 *Long-term ring-bending strain* S_b. Long-term ring-bending strain can be determined with creep-failure tests instrumented to detect an abrupt, significant reduction in mechanical properties. The test data should be statistically extrapolated to establish strength at 50 years. The value for S_b may be determined by testing per ASTM D5365, using a water test solution with any pH between 5 and 9. If these test results are not available, the value for S_b may be taken as the results of either of the following testing methods:

1. In accordance with ASTM D3681, using 1*N* H_2SO_4.
2. Using results of ASTM D2992, method B, extrapolated to 50 years.

Sec. 4.9 Joint Types and Requirements

The pipe shall have a joining system that shall provide for fluid tightness for the intended service condition.

4.9.1 *Unrestrained.* Pipe joints capable of withstanding internal pressure but not longitudinal forces.

4.9.1.1 Coupling or bell-and-spigot gasket joints. Joints with a groove on either the spigot or in the bell to retain an elastomeric gasket that shall be the sole element of the joint to provide watertightness.

4.9.1.2 Mechanical couplings with elastomeric seals.

4.9.2 *Restrained.* Pipe joints capable of withstanding internal pressure and longitudinal forces.

4.9.2.1 Joints similar to the joints in Sec. 4.9.1.1 with supplemental restraining elements.

4.9.2.2 Butt joint with laminated overlay.

4.9.2.3 Bell-and-spigot with laminated overlay.

4.9.2.4 Bell-and-spigot adhesive bonded. Three types of adhesive-bonded joints are permitted by this standard. Each shall meet or exceed the hoop tensile and axial tensile strength requirements of the pipes as prescribed in Sec. 5.1.2.3 and Sec. 5.1.2.4. The permissible adhesive-bonded joints are as follows:

1. Tapered bell and spigot: An adhesive joint that is manufactured with a tapered socket for use in conjunction with a tapered spigot section and a suitable adhesive.
2. Straight bell and spigot: An adhesive joint that is manufactured with an untapered socket for use with a pipe with an untapered spigot and a suitable adhesive.
3. Tapered bell and straight spigot: An adhesive joint that is manufactured with a tapered socket to be used with a pipe with an untapered spigot and a suitable adhesive.

4.9.2.5 Flanged. Both integral and loose ring.

4.9.2.6 Mechanical. Elastomeric sealed with supplemental restraining elements.

4.9.3 *Performance requirements.*

4.9.3.1 Joint tightness. All joints shall meet the Laboratory Performance Requirements of Sec. 7 of ASTM D4161. Rigid joints (see Sec. 4.9.2.2, Sec. 4.9.2.3, Sec. 4.9.2.4, and Sec. 4.9.2.5) shall be exempt from angular deflection requirements.

4.9.3.2 Gaskets. Elastomeric gaskets shall conform to the requirements of ASTM F477.

Copyright by the American Water Works Association
Wed Feb 02 02:14:57 2005

NOTE: The inclusion of longitudinal joint restraints may increase service loads on the pipe to be greater than those experienced with unrestrained joints. The purchaser is cautioned to take into consideration all conditions that may be encountered in the anticipated service and to consult with the manufacturer regarding the suitability of a particular type and class of pipe for service with restrained joints.

SECTION 5: VERIFICATION

Sec. 5.1 Inspection and Testing

5.1.1 *Plant inspection by purchaser.* Plant inspection by the purchaser or the omission of such inspection shall not relieve the manufacturer of the responsibility to furnish products that comply with the applicable requirements of this standard and of the purchaser.

5.1.1.1 Production notice. When plant inspection is specified by the purchaser, the manufacturer shall provide the purchaser with adequate advance notice of when and where the production of ordered products will commence.

5.1.1.2 Inspection limitations. If a manufacturer desires to exclude inspection of proprietary manufacturing processes, the manufacturer shall so advise the purchaser.

5.1.1.3 Plant access. The purchaser's agent shall have free access to those parts of a manufacturer's plant that are necessary to assure that products comply

with all requirements of this standard and of the purchaser. Access may be limited to areas of the manufacturer's plant not specifically excluded by the terms of Sec. 5.1.1.2.

5.1.1.4 Inspection aids. The manufacturer shall make available to the purchaser's agent, without charge, such tools and assistance as are necessary for inspection and handling of materials.

5.1.2 *Quality control tests and records.* The manufacturer shall take adequate measures in the production of products to assure compliance with the requirements of this standard. To ensure compliance, the following tests shall be performed at the indicated intervals, unless otherwise specified by the purchaser. The manufacturer shall maintain a record of all quality control tests for a period of not less than two years and, if requested, shall submit the data to the purchaser.

5.1.2.1 Hydrostatic leak tests. Unless otherwise agreed on by the purchaser and supplier, the manufacturer shall perform hydrostatic leak tests to all pipe sizes 1 in. through 54 in. (25 mm through 1,400 mm). For sizes greater than 54 in. (1,400 mm), the frequency of hydrostatic leak tests shall be as agreed on by the manufacturer and purchaser. The pipe shall not fail, leak, or weep when tested at ambient temperatures according to Sec. 5.1.2.1.1.

5.1.2.1.1 A length of pipe, when tested, shall be placed in a hydrostatic-pressure test machine that seals the ends of the pipe. The pipe shall be filled with water,

expelling all air, and an internal water pressure shall be applied at a uniform rate until a pressure of two times the pressure class is reached (see Table 7). This test pressure shall be maintained for at least 30 s. The pipe shall show no visual signs of weeping or leakage. Integral bells, including reinforcement sleeves, if any, or affixed couplings, shall be tested with the pipe.

5.1.2.2 Stiffness tests. The manufacturer shall perform stiffness tests at a frequency of one test for each 100 lengths of pipe produced or from each manufacturing run, whichever provides the most frequent sampling of each class and size. The minimum pipe stiffness ($F/\Delta y$) shall be determined at 5 percent deflection using the apparatus and procedure of ASTM D2412, with three exceptions. The exceptions are (1) the wall thickness shall be measured to the nearest 0.01 in. (0.25 mm); (2) the specimen taken from the pipe barrel shall be loaded to 5 percent deflection, the load shall be recorded, and the specimen shall be examined for evidence of crazing or cracking; and (3) test frequency shall be as specified in this paragraph.

5.1.2.2.1 The pipe shall exhibit, without structural damage, the minimum stiffness specified in Table 8 when tested in accordance with Sec. 5.1.2.2.

5.1.2.2.2 At deflection level A (Table 9), there shall be no visual evidence, when inspected without magnification, of cracking or crazing in a sample of the pipe barrel. At deflection level B (Table 9), there shall be no visual indication, when inspected without magnification, of structural damage to the pipe wall evidenced by interlaminar separation, tensile failure of the glass-fiber reinforcement, fracture, or buckling of the pipe wall. Both level A and level B criteria must be met. The pipe stiffness test specimen may be used for these tests.

NOTE: The deflection criteria presented in Table 9 are based on a maximum installed long-term field deflection of 5 percent. If the pipe sample fails to meet either or both requirements (that is, for levels A and B), the long-term allowable deflection must be reduced proportionally for the pipes represented by the sample.

Table 7 Hydrostatic leak test pressure requirements

Pressure Class		Hydrostatic Test Pressure	
psi	*kPa*	*psi*	*kPa*
50	345	100	689
100	689	200	1,379
150	1,034	300	2,068
200	1,379	400	2,758
250	1,724	500	3,447

Table 8 Minimum pipe stiffness requirements for 5 percent deflection

Nominal Pipe Size		Stiffness Class—*psi (kPa)*			
		9 (62)	18 (124)	36 (248)	72 (496)
in.	*(mm)*	Minimum Pipe Stiffness Required—*psi (kPa)*			
1–8	(25–200)	NR*	NR	36.0 (248)	72.0 (496)
10	(250)	NR	18.0 (124)	36.0 (248)	72.0 (496)
12–144	(300–3,600)	9.0 (62)	18.0 (124)	36.0 (248)	72.0 (496)

	Stiffness Class—*psi (kPa)*			
	9 (62)	18 (124)	36 (248)	72 (496)
Deflection Level	Initial Ring Deflection—% of diameter			
A	18	15	12	9
B	30	25	20	15

5.1.2.3 Hoop tensile strength tests. The manufacturer shall perform hoop tensile strength tests at a frequency of one test for each 100 lengths of pipe produced or from each manufacturing run, whichever provides the most frequent sampling of each class and size. The minimum hoop tensile strength properties shall be determined from the average of the test results of three specimens cut from the sample when using the apparatus and procedure of one of the following test methods:

1. ASTM D2290, procedure A. Specimen width shall be appropriate to the diameter and wall thickness of the pipe. Reduced-section specimens are acceptable. A test apparatus with a varying rate of motion may be used, provided the speed of testing does not exceed 0.10 in./min (2.5 mm/min) in accordance with procedure A. Except in cases of disagreement, routine quality control tests may be performed at ambient conditions of temperature and humidity, and calculations need not include the standard deviation.

2. ASTM D638. The widths of specimens may be increased for pipe wall thicknesses greater than 0.55 in. (14 mm). Means may be provided to minimize the bending moment imposed during the test. Except in cases of disagreement, calculations from routine quality control test results need not include the standard deviation.

3. ASTM D1599.

5.1.2.3.1 The pipe shall meet or exceed the minimum short-term hoop tensile strength calculated by Eq 1 or Eq 2, whichever is greater. The minimum short-term hoop tensile strengths calculated per Eq 2 are given in Table 10.

$$F = \frac{S_i}{S_r}(Pr) \qquad \text{(Eq 1)}$$

$$F = 4.0\,(Pr) \qquad \text{(Eq 2)}$$

Where:

F = required minimum hoop tensile strength, lbf per inch of width (kN/m)
S_i = initial design hoop tensile strength, psi (kPa)
S_r = hoop tensile stress at pressure class, psi (kPa)
P = specified pressure class from Table 7, psi (kPa)
r = nominal pipe radius, in. [(OD—single wall thickness)/2] (m)

5.1.2.3.2 The values of S_i and S_r should be established from the manufacturer's long-term hydrostatic tests performed in accordance with Sec. 4.6.2. S_i shall be taken as the 95 percent lower-confidence level, back extrapolated to 0.1 h. This

Wed Feb 02 02:14:59 2005

takes into consideration variations in glass-fiber strength and manufacturing methods. S_r is the calculated hoop tensile stress at the pressure class.

5.1.2.4 Axial tensile strength tests. The manufacturer shall perform axial tensile strength tests at a frequency of one test for each 100 lengths of pipe produced or from each manufacturing run, whichever provides the most frequent sampling of each class and size. The minimum axial tensile strength shall be determined from the average of the test results of three specimens cut from the sample when using the apparatus and procedure of ASTM D638 or ASTM D2105, depending on the size of the pipe specimens to be tested.

5.1.2.4.1 The pipe shall meet or exceed the minimum axial tensile strength requirements listed in Table 11 when tested in accordance with ASTM D638 or ASTM D2105. The values in Table 11 are the minimum criteria and are based on buried pipe fully restrained in the axial direction due to soil friction. The values may not be indicative of the axial strength of some products or of the axial strength required under certain installation conditions and joint configurations.

5.1.2.5 Beam-strength tests. The beam-strength test is a design-qualification test required only when there is a significant change in the design or construction of the pipe. A significant change is considered to occur when the average axial tensile strength as determined in Sec. 5.1.2.4 decreases more than 15 percent. Two methods can be used.

Method 1: Method 1 can be used for pipe sizes up to and including 27 in. (700 mm). In method 1, the pipe shall withstand, without failure, the beam loads listed in Table 12 when tested in accordance with the beam-strength test method of ASTM D3517.

Method 2: Method 2 can be used for all pipe sizes. In method 2, the pipe shall meet or exceed (1) the minimum axial tensile strength listed in Table 11 when tested in accordance with Sec. 5.1.2.4; and (2) the minimum axial compressive strength listed in Table 13 when tested in accordance with ASTM D695.

5.1.2.6 Dimensions. The manufacturer shall inspect one length per 100 lengths of pipe before shipment for dimensions and tolerances outlined in Sec. 4.5.

Sec. 5.2 Rejection and Retesting

If the results of any test do not conform to the requirements of this standard, then that test may be repeated on two additional samples from the same lot of pipe. Each of the two samples shall conform to the requirements specified. If either of the two additional samples fail, the lot may be rejected, at the option of the purchaser. Rejection should be reported to the manufacturer or supplier promptly and in writing.

SECTION 6: DELIVERY

Sec. 6.1 Marking

Each standard length and random length shall be clearly marked. Marking shall be applied without indentation so as to remain legible during normal handling and installation practices. At a minimum, these markings shall consist of the following: (1) the phrase *AWWA C950*; (2) nominal pipe size, cell classification, and diameter series; (3) AWWA pressure class; (4) stiffness class; and (5) manufacturer's mark and identity code.

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

Committee Personnel

The D103 Task Force that developed this standard had the following personnel at that time:

Francis Grillot Jr., *Chair*

Consumer Member

A.J. Hamlett Jr., Tulsa Public Works Department, Tulsa, Okla. (AWWA)

General Interest Member

J.E. Rudina, AEC Engineering, Minneapolis, Minn. (AWWA)

Producer Members

N.C. Bailey, Conservatek Industries Inc., Conroe, Texas (AWWA)
R.W. Cooper, Columbian Steel Tank Company, Kansas City, Kan. (AWWA)
John Farris, Peabody TecTank Inc., Parsons, Kan. (AWWA)
R.V. Field, A.O. Smith Engineered Storage Products Company, DeKalb, Ill. (AWWA)
Francis Grillot Jr., Temcor, Carson, Calif. (AWWA)
G.C. Margolf, Temcor, Carson, Calif. (AWWA)
D.A. Turner, Peabody TecTank Inc., Parsons, Kan. (AWWA)
L.D. Scott, Trustco Tank Inc., San Luis Obispo, Calif. (AWWA)
Mark Workman, Columbian Steel Tank Company, Kansas City, Kan. (AWWA)

The Standards Committee on Steel Elevated Tanks, Standpipes, and Reservoirs that reviewed and approved this standard had the following personnel at the time of approval:

E. Crone Knoy, *Chair*

Consumer Members

S.F. Crumb, Fort Worth Water Department, Fort Worth, Texas (AWWA)
Ed Darrimon, Bay Area Coating Consultants, Modesto, Calif. (AWWA)
W.H. Harris, City of Houston, Houston, Texas (AWWA)
Joseph Ortiz, East Bay Municipal Utility District, Oakland, Calif. (AWWA)
E.J. King,* Connecticut Water Company, Clinton, Conn. (NEWWA)
K.A. Nadeau, Connecticut Water Company, Clinton, Conn. (NEWWA)
A.R. Terrell Jr., Little Rock Municipal Water Works, Little Rock, Ark. (AWWA)
G.A. Weeks, St. Louis County Water Company, St. Louis, Mo. (AWWA)

Foreword

This foreword is for information only and is not a part of AWWA D103.

I. Introduction.

I.A. *Background.* This standard covers factory-coated bolted steel tanks for water storage and is based on the accumulated knowledge and experience of manufacturers of bolted steel tanks.*

I.B. *History.* The first version of this standard was prepared in cooperation with the Bolted Tank Manufacturer's Association and was issued in 1980. It was prepared in response to the increasing use of bolted tanks for water storage. AWWA D103-80 was later updated and approved as AWWA D103-87 on June 14, 1987. The third and current edition of ANSI/AWWA D103-97 was approved by the AWWA Board of Directors on June 15, 1997.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International (NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other members of the original consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA) and the Association of State Drinking Water Administrators (ASDWA) joined later.

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.† Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.
3. Two standards developed under the direction of NSF, ANSI‡/NSF§ 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.
4. Other references, including AWWA standards, *Food Chemicals Codex*, *Water Chemicals Codex*,** and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to

*The word *tanks* is used hereinafter broadly in place of the lengthy phrase *standpipes or reservoirs for water storage.*

†Persons in Canada, Mexico, and non-North American countries should contact the appropriate authority having jurisdiction.

‡American National Standards Institute, 11 W. 42nd St., New York, NY 10036.

§NSF International, 3475 Plymouth Rd., Ann Arbor, MI 48106.

**Both publications available from National Academy of Sciences, 2102 Constitution Ave. N.W., Washington, DC 20418.

accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

AWWA D103-97 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues.

II.A. *Purchase.* When tanks are purchased using this standard, the purchaser must specify certain basic requirements. The purchaser may desire to modify, delete, or amplify sections of this standard to suit special conditions. It is strongly recommended that such modifications, deletions, or amplifications be made by supplementing this standard rather than by rewriting or incorporating sections from this standard into a separate specification.

II.B. *Design and Construction.* The details of design and construction covered by this standard are minimum requirements. A tank cannot be represented as adhering to the provisions of AWWA D103 if it does not meet the minimum requirements of this standard.

II.C. *Coatings.* Tanks covered by this standard shall be supplied with factory-applied coatings. Field coating is limited to repair of damaged coatings.

Tanks with factory-applied coatings and bolted construction have a long life expectancy. Regular inspection and repair of damaged or deteriorated areas may be the determining factors in the length of tank life.

II.D. *Foundations.* Tank foundations are one of the more important aspects of tank design. Detailed requirements for tank foundations are covered in Sec. 11 of this standard. This standard does not require the manufacturer or constructor to be responsible for the design of the tank foundation unless otherwise specified by the purchaser. Unless otherwise specified by the purchaser, the purchaser must obtain an adequate soil investigation at the tank site, including recommendations of the type of foundation to be used, the depth of foundation required, and the design soil-bearing pressure. This information, as well as specifications for an adequate soil investigation, should be established by a qualified geotechnical engineer. The top of the foundation should be 6 in. minimum above the finished grade, unless otherwise specified by the purchaser.

A drainage inlet structure or suitable erosion protection should be provided to receive the discharge from the tank overflow. The overflow shall not be connected directly to a sewer or a storm drain without an air break.

II.E. *Annual Inspection and Maintenance.* Inspection and maintenance is important if maximum tank life is to be attained. Inspections should occur at least every 3 to 5 years. In particular, accumulations of dirt and weeds from around the outside base of the tank, which may trap moisture and accelerate corrosion, as well as accumulated silt inside on the floor, should be removed.

Copyright by the American Water Works Association
Wed Feb 02 02:15:37 2005

II.F. *Disinfection Procedures and Cathodic Protection.* This standard does not cover disinfecting procedures* (see Sec. 9.4) or cathodic protection.

1. If the disinfecting is to be done by the tank constructor, the purchaser must specify how such disinfecting is to be done.
2. The purchaser is responsible for determining the need for, the design of, and the specifications for cathodic protection (see ANSI/AWWA D104).

II.G. *Recommended Items to Be Furnished by the Purchaser and Manufacturer.* The following recommendations on items to be furnished by both the purchaser and the manufacturer are considered good practice, but are not requirements of ANSI/AWWA D103.

When a bolted steel tank is to be purchased under the provisions of this standard, the purchaser should provide the following:

1. The site on which the tank is to be built, including sufficient space to permit the structure to be erected by customary methods.
2. Foundation design and construction unless otherwise specified.
3. Water at the proper pressure for testing, as required, and facilities for disposal of wastewater after testing.
4. A suitable right-of-way from the nearest public road to the erection site.
5. Any materials furnished by the purchaser to be used by the constructor for construction of the tank.

The manufacturer should furnish the following:

1. Foundation loads and reactions imposed on the foundations by the tank.
2. Anchor bolts, if required, for wind, earthquake, or other lateral loads, or if specified to be furnished.
3. All labor and materials, except materials furnished by the purchaser, that are necessary to manufacture the structure components, including the accessories required by this standard.

Variations in the responsibilities of both the purchaser and the manufacturer as previously outlined may be made by the contractual agreement. The purchaser and the bidder should each furnish information identified in the sections that follow.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Purchaser Options and Alternatives.* The following information should be furnished by the purchaser when taking bids for a standpipe or reservoir:

1. For standpipes, the capacity and top capacity level.
2. For reservoirs, the capacity and diameter.
3. Desired time for completion.
4. Site location.
5. Type of road available for access to the site, and whether the road is public or private.
6. Name of and distance to the nearest town.
7. Name of and distance to the nearest railroad siding.

*Various disinfection procedures are presented in AWWA C652, Standard for Disinfection of Water-Storage Facilities.

Copyright by the American Water Works Association
Wed Feb 02 02:15:37 2005

8. Availability of electric power; who furnishes it and at what fee, if any; what voltage is available; whether direct or alternating current; and, if alternating current, what cycle and phase.

9. Availability of compressed air and what pressure, volume, and fee are available, if any.

10. The bottom capacity level of the tank when empty if different from the level when the tank would be emptied through the specified discharge piping (Sec. 1.2.9).

11. The type of pipe and fittings for fluid conductors and the type of pipe joint if different from that permitted in Sec. 2.9.

12. If snow loading is to be omitted when the tank is located in an area where actual snow loading is insignificant (Sec. 3.2.3).

13. Specific wind-load requirements, including whether a sliding check for unanchored tanks is required (Sec. 3.2.4).

14. Unless the purchaser specifies that seismic design be omitted, all seismic designs will be based on pseudo-dynamic criteria (Sec. 12). When seismic design is required, purchaser shall identify which zone—1, 2A, 2B, 3 or 4—is to be used.

15. Locations of manholes, ladders, and any additional accessories required (Sec. 5).

NOTE: Only one shell manhole will be provided unless the purchaser otherwise specifies (Sec. 5.1).

16. The number and location of pipe connections, and type and size of pipe to be accommodated.

NOTE: Connections to the piping furnished by the constructor are to be made by the purchaser (Sec. 5.2).

17. If a removable silt stop is required (Sec. 5.2.1).

18. Overflow type, whether stub or to ground; size of pipe; pumping and discharge rates (Sec. 5.3).

19. If the roof ladder for providing access to roof hatches and vents is to be omitted (Sec. 5.4.3).

20. If safety cages, rest platforms, ladder locks, roof-ladder handrails, or other safety devices are required, and on which ladders (Sec. 5.5).

NOTE: The purchaser should specify the beginning location of the outside tank ladder if it is other than 8 ft above the level of the tank bottom.

21. If a special vent is required for screening the tank vent (Sec. 5.7).

22. If shop inspection is required, and whether typical mill-test reports are required (Sec. 9.1).

23. Unless otherwise specified, soil investigation, including foundation-design criteria (Sec. 11.2), type of foundation (Sec. 11.4.1), depth of foundation below existing grade, and design soil-bearing pressure, including factor of safety.

NOTE: The top of the foundation is to be 6 in. minimum above the finish grade unless otherwise specified by the purchaser (Sec. 11.5.1).

24. If a steel tank bottom or a steel base setting ring is to be used (Sec. 11.4.1, type 6).

25. When a pile-supported foundation is required, the purchaser should specify pile type and depth below existing grade (Sec. 11.5.4).

26. If all requirements of ACI 301, Specifications for Structural Concrete for Buildings, are applicable to the concrete work (Sec. 11.6).

27. Vertical distance from finished ground level to the crown of inlet and outlet pipes (that is, pipe cover) at tank foundation (Sec. 11.7.2).

Copyright by the American Water Works Association
Wed Feb 02 02:15:38 2005

28. Completion of the Tabulation Form for Seismic Data when seismic design is required (Sec. 12.1.2).

29. If vertical acceleration is to be considered and how it is to be applied in seismic design (Sec. 12.3.7.1).

30. Amount of freeboard for sloshing wave (Sec. 12.3.7.2).

31. If seismic design of roof framing and columns is required (Sec. 12.3.7.3), and the amount of live loads and vertical acceleration to be used.

32. If local seismic data are available and if they are to be used in place of acceleration and spectral velocity values (Sec. 12.4) and the reduction factor to be used if scaled-down response spectra are used (Sec. 12.4.1).

33. If an aluminum dome roof is to be provided as discussed in Sec. 13.

34. If the aluminum dome roof is to be provided, whether the exterior of the dome is to have a factory-applied baked-on finish.

III.B. *Information to Be Furnished by the Manufacturer or Constructor.* The following information shall be furnished by the manufacturer or constructor for a standpipe or reservoir:

1. Dimensions of the standpipe or reservoir, including the diameter, shell height type of bottom, type of roof, type of coating, details of bolted joints, and type and size of plates, members, and anchorages shall be identified. The gross moment and shear imparted to the foundation under seismic and wind loading should also be identified at the time of the bid.

2. The number, names, and sizes of all accessories. This includes the type of roof ladder if an alternative method from that required in Sec. 5.4.3 is proposed.

3. If the purchaser specifies that the tank is to be cathodically protected, the constructor shall certify in the bid that the tank will be erected so as to provide electrical continuity of all tank components in contact with water.

III.C. *Items for Consideration by the Purchaser.* The design, construction, and final placement of a storage tank into service requires cooperation between the purchaser, manufacturer, and constructor of the tank. Various practices are used to ensure successful tank placement. The following items are suggested for inclusion in the purchaser's specifications, unless local practice dictates otherwise. Please note that this material is not stipulated in the text of ANSI/AWWA D103.

1. The purchaser may want to provide for field inspection to be performed either by the purchaser or by a commercial inspection agency, the cost of which shall be paid by the purchaser. As an option, the purchaser may require the manufacturer or constructor to perform the inspection work and, at the conclusion of the work, to submit a written report. The report should include a statement indicating that the tank has been erected according to the manufacturer's instructions, that the required testing has been performed, and that any leaks have been repaired.

2. The roof opening in the tank should be located near the overflow to provide for visual inspection of the overflow.

3. This standard assumes that the purchaser (owner) provides sufficient water replacement and circulation to prevent freezing in the tank and riser pipe. Where low usage may result in the possibility of freezing, the purchaser shall waste water or provide heat to prevent freezing. The purchaser is referred to National Fire Protection Association (NFPA)* document NFPA 22, Water Tanks for Private Fire Protection, for heater sizing. Purchasers are cautioned against allowing ice to build

*National Fire Protection Association, One Batterymarch Park, Quincy, MA 02269.

Copyright by the American Water Works Association
Wed Feb 02 02:15:38 2005

up for use as insulation because the ice may break loose and damage the tank. Where reference to ice damage is discussed in the standard, it is in anticipation of improper operation rather than approval of an icing condition.

4. On completion of the tank erection, it is recommended that the constructor dispose of all rubbish and other unsightly material caused by the operations and leave the premises in as good a condition as found at the start of the tank erection. It is recommended that the purchaser provide appropriate containers for placement and removal of disposed materials. Section 8.5 of ANSI/AWWA D103 does not list requirements for cleanup.

5. ANSI/AWWA D103 does not require the manufacturer or constructor to blind and fill the tank to top capacity level, according to the manufacturer's recommendations (see Sec. 9.2). It is common practice for the purchaser to provide this effort. Should the purchaser require that the manufacturer or constructor provide this service and a supply of water, this must be provided for in the purchaser's specifications.

6. ANSI/AWWA D103 does not require the manufacturer or constructor to furnish foundation plans (see Sec. 11.1.1). Should the purchaser specify submission of foundation plans, the purchaser must furnish adequate information relative to the type of foundation, foundation depth, and allowable soil-bearing pressure. (See Sec. II.D of the foreword and Sec. 11 for further information.)

7. ANSI/AWWA D103 does not require the manufacturer or constructor to construct and install a foundation. Should the purchaser require that a foundation be provided by the manufacturer or constructor, any information other than that contained in Sec. 11 of this standard must also be provided by the purchaser.

8. It is recommended that the purchaser retain a qualified geotechnical consultant to conduct a proper soil investigation. Unless otherwise specified by the purchaser, ANSI/AWWA D103 does not require that the manufacturer or constructor provide this service (see Sec. 11.3).

9. ANSI/AWWA D103 does not require the manufacturer or constructor to provide specifications for the preparation of sub-base materials (Sec. 11.4.1.6). Should the purchaser require that the manufacturer or constructor provide such specifications, this must be provided in the purchaser's specifications.

III.D. *Modification to Standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. Major changes made to the standard in this revision include the following:

1. The format of the foreword has been changed to AWWA standard style.

2. The acceptance clause (Sec. I.C) and the definitions of parties (Sec. 3) have been revised to approved wording.

3. Changes have been made to Sec. 12, Seismic Design of Flat-Bottomed Water Storage Tanks, to reflect the changes made to ANSI/AWWA D100, Standard for Welded Steel Tanks for Water Storage.

4. A new Sec. 13 was created for structurally supported aluminum dome roofs, which replaces appendix A.

V. Comments. If you have any comments or questions about this standard, please call the AWWA Standards and Materials Development Department, (303) 794-7711 ext. 6283, FAX (303) 795-1440, or write to the department at 6666 W. Quincy Ave., Denver, CO 80235.

ANSI/AWWA D103-97
(Revision of ANSI/AWWA D103-87)

AWWA STANDARD FOR

FACTORY-COATED BOLTED STEEL TANKS FOR WATER STORAGE

SECTION 1: GENERAL

Sec. 1.1 Scope

The purpose of this standard is to facilitate the manufacture, installation, and procurement of cylindrical bolted steel tanks for the storage of water.

1.1.1 *Tank roofs.* All tanks storing potable water shall have roofs. Tanks storing nonpotable water may be constructed without roofs.

1.1.2 *Work outlined.* The work to be performed by the parties in completing the activities described in this standard is outlined as follows:

1. Foundation constructor:

Section 2, Materials. See Sec. 2.3 for foundation-reinforcing steel.

Section 11, Foundation Design and Construction. The constructor or purchaser is responsible for construction of the foundation. The purchaser is responsible for the design of the foundation.

2. Manufacturer:

Section 2, Materials (except as indicated in item 1 above.)
Section 3, General Design.
Section 4, Sizing of Standpipes and Reservoirs.
Section 5, Accessories for Standpipes and Reservoirs.
Section 6, Welding.
Section 7, Shop Fabrication.
Section 9, Inspection and Testing. See Sec. 9.1 regarding shop inspection.
Section 10, Coatings (except as indicated in item 3).
Section 12, Seismic Design of Flat-Bottom Water-Storage Tanks.

3. Constructor of tank:

Section 6, Welding. (To be used in the field only after prior acceptance by the manufacturer and purchaser.)
Section 8, Erection.
Section 9, Inspection and Testing (except as indicated in item 2).

Copyright by the American Water Works Association
Wed Feb 02 02:15:38 2005

Section 10, Coatings. See Sec. 10.2 regarding coating repair to be done in the field.

1.1.3 *Items not covered.* This standard does not cover all details of design and construction because of the large variety of sizes and shapes of tanks. Where details for any specific design are not given, the manufacturer, subject to the approval of the purchaser, shall provide details that are designed and constructed to be as adequate and as safe as those that would otherwise be provided under this standard.

1.1.4 *Local requirements.* This standard is not intended to cover storage tanks erected in areas subject to regulations more stringent than the requirements contained within this standard. In such cases, this standard should be followed on purchases made under the provisions of this standard, insofar as it does not conflict with local requirements. Where more stringent local, municipal, county, or state government requirements exist, such requirements may govern, and this standard shall be interpreted to supplement them.

Sec. 1.2 Definitions

The following definitions shall apply in this standard:

1.2.1 *Capacity:* The net volume that may be removed from a tank filled just to the top capacity level and emptied to the bottom capacity level. The bottom capacity level, if not otherwise specified by the purchaser, shall be the water level in the tank shell when the tank is emptied through the specified discharge piping.

1.2.2 *Constructor:* The party that furnishes the work and materials for placement or installation.

1.2.3 *Manufacturer:* The party that manufactures, fabricates, or produces materials or products.

1.2.4 *Purchaser:* The person, company, or organization that purchases any materials or work to be performed.

1.2.5 *Reservoir:* A flat-bottom cylindrical tank having a shell height equal to or smaller than its diameter.

1.2.6 *Standpipe:* A flat-bottom cylindrical tank having a shell height greater than its diameter.

1.2.7 *Tank:* A standpipe or a reservoir used for water storage.

Sec. 1.3 Responsibilities of Parties

1.3.1 *Manufacturer's responsibility.* The manufacturer shall furnish a structure free of defective materials, including coatings. This responsibility shall be in effect for a period of one year from the date of completion but not more than 14 months from the date of delivery. Any materials proven to be defective within this time shall be replaced or repaired by the manufacturer.

1.3.2 *Constructor's responsibility.* The constructor shall erect the structure free of defects in workmanship. This responsibility shall be in effect for a period of 12 months from the date of acceptance but not more than 12 months from the date of completion of installation by the constructor. Any faulty workmanship found within those periods shall be repaired by the constructor.

1.3.3 *Inspection and repair of tank.* The purchaser must provide the constructor and the manufacturer with the opportunity to inspect and repair the tank, if required, within the responsibility periods enumerated in Sec. 1.3.1 and 1.3.2. Failure of the purchaser to provide an opportunity to inspect within these periods will relieve the constructor and manufacturer of responsibility unless otherwise agreed.

Sec. 1.4 Drawings to Be Furnished

After award of the contract the manufacturer shall prepare the anchor-bolt layout, when applicable, and assembly drawings, which are to be submitted to the purchaser for approval unless waived, before proceeding with any fabrication. If required by the purchaser, details of all bolted and welded joints shall be referenced on the drawings.

Sec. 1.5 References

This standard references the following documents. In their latest editions, they form a part of this standard to the extent specified within the standard. In any case of conflict, the requirements of this standard shall prevail.

AA* SPC—Standards for Aluminum Sand and Permanent Mold Castings.

AA SAS—Specifications for Aluminum Structures (Sec. 1).

AAMA† 605—Voluntary Specification for High Performance Organic Coatings on Architectural Extrusions and Panels.

ACI‡ 301—Standard Specification for Structural Concrete.

ACI 318—Building Code Requirements for Structural Concrete.

AISC§ ASD—Specification for Structural Steel Buildings—Allowable Stress Design.

AISI** 1010—Carbon Steel: Plates; Structural Shapes; Rolled Floor Plates; Steel Sheet Piling.

AISI SG-673—Specification for the Design of Cold-Formed Steel Structural Members.

ANSI††/ASTM‡‡ A6—Standard Specification for General Requirements for Rolled Steel Bars, Plates, Shapes, and Sheet Piling.

ANSI/ASTM A36—Standard Specification for Carbon Structural Steel.

ANSI/ASTM A53—Standard Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless.

ANSI/ASTM A181—Standard Specification for Carbon Steel for Forgings, for General-Purpose Piping.

ANSI/ASTM A194—Standard Specification for Carbon and Alloy Steel Nuts for Bolts for High-Pressure and High-Temperature Service.

ANSI/ASTM A216—Standard Specification for Steel Castings, Carbon, Suitable for Fusion Welding, for High-Temperature Service.

ANSI/ASTM A572—Standard Specification for High-Strength Low-Alloy Columbium-Vanadium Structural Steel.

Fed Spec. ZZ-R-765—Rubber Silicone: Low- and High-Temperature and Tear Resistant.

SECTION 2: MATERIALS

Sec. 2.1 General

All materials to be incorporated in any structure to meet the provisions of this standard shall be new, previously unused, and in first-class condition, and shall comply with all of the requirements of this standard.

Sec. 2.2 Bolts and Anchor Bolts

2.2.1 *Bolts.* Bolts for joining tank panels shall conform to the requirements of ASTM A307, ASTM A325, ASTM A490, or API 12B. Nuts for these bolts shall conform to ANSI/ASTM A194 or ASTM A563.

2.2.2 *Anchor bolts.* Anchor bolts shall conform to the requirements of ANSI/ASTM A36, ASTM A307, or ANSI/ASTM A572, grade 50.

Sec. 2.3 Foundation-Reinforcing Steel

Reinforcing steel in foundations shall comply with the requirements of ACI 318.

Sec. 2.4 Plates and Sheets

Plate and sheet materials shall be open-hearth, electric-furnace, or basic-oxygen-process steel conforming to any of the following ASTM specifications: A36; A283, grade C or D; A570, grade 30, 33, 36, 40, 45, or 50; A572, grade 42, 50, or 60; A607, grade 50, 55, or 60; or A715, grade 50. Plates and sheets may be furnished on the weight basis, with permissible underrun according to the tolerance table for plates ordered to weight published in ANSI/ASTM A6 and for sheets ordered to weight published in ASTM A568. Steel grades designating a yield strength of 50,000 psi or more should not be used on 15-ft or smaller diameter tanks that have form-flanged connections.

*National Fire Protection Association, One Batterymarch Park, Quincy, MA 02269.

†Steel Structures Painting Council, 40 24th St., Ste. 600, Pittsburgh, PA 15222-4643.

‡Federal Specifications, Superintendent of Documents, US Government Printing Office, Washington, DC 20402.

Wed Feb 02 02:15:39 2005

Sec. 2.5 Structural Shapes

Hot-rolled structural shapes for use under the provisions of this standard shall conform to AISC S335. Material shall conform to ANSI/ASTM A36 or AISI 1010. Aluminum shapes of a suitable alloy for load and service requirements may be used for portions of the tank not in contact with water. The design of all aluminum members shall be in accordance with AA SAS and to the loads specified in Sec. 3 of this standard.

Sec. 2.6 Castings

Iron castings shall conform to ASTM A48, class 30. Steel castings shall conform to ANSI/ASTM A216, grade WCB. Aluminum castings shall conform to AA SPC.

Sec. 2.7 Forgings

2.7.1 *Forgings from plate and sheet materials.* Forgings from plate and sheet materials shall conform to the plate and sheet materials permitted under Sec. 2.4.

2.7.2 *Forgings from other than plate or sheet materials.* Forgings from other than plate or sheet materials shall conform to ANSI/ASTM A668, class E.

2.7.3 *Forged and rolled pipe flanges.* Forged and rolled pipe flanges shall conform to ASTM A181, class 60.

Sec. 2.8 Electrodes

Manual, shielded-metal, arc-welding electrodes shall conform to the requirements of AWS A5.1. Welding electrodes shall be of any E60XX or E70XX classification suitable for the electric current characteristics, the position of welding, and other conditions of intended use. Welding electrodes for other welding processes shall conform to applicable AWS specifications for filler metal.

Sec. 2.9 Pipe for Fluid Conductors

Inlet, outlet, overflow, and other pipes, and all fittings for fluid use shall be as specified by the purchaser. If steel pipe is not otherwise specified, it shall conform to or exceed ANSI/ASTM A53 carbon steel or ASTM A240 300 series stainless steel. Unless otherwise specified, joints may be either screwed or flanged at the option of the manufacturer. Pipe and fittings from warehouse stock may be used if certified by the warehouse to be in accordance with this standard or the purchaser's specifications.

Sec. 2.10 Gaskets and Sealants

The manufacturer shall use gaskets or sealants or a combination of both in accordance with the following requirements.

2.10.1 *Gaskets.* Gasket material shall be of adequate tensile strength and resilience to obtain a leak-proof seal at all seams and joints. Gasket material shall be resistant to weather and ozone exposure as designated by ASTM D1171. Physical requirements are described in Table 1.

2.10.2 *Sealants.* Sealants shall comply with the following:

1. Resistance to temperature. The sealant shall remain flexible when in continuous operation over a temperature range of –40°F to +170°F (–40°C to +76.7°C).

2. Weatherability. The sealant shall be resistant to hardening and cracking. The sealant shall be essentially solid and contain no plasticizers or extenders that could cause shrinkage due to weathering. The sealant shall be resistant to ozone and ultraviolet light.

Copyright by the American Water Works Association
Wed Feb 02 02:15:40 2005

Table 1 Physical requirements for gasket material*

Description	Strip and Extruded Gasket Material
Tensile strength, initial, psi minimum, ASTM D412	1,200 psi 8,274 kPa
Tensile strength after oven aging as percent of initial, minimum, ASTM D573	70%
Tensile strength after immersion in distilled water as percent of initial, minimum, ASTM D471	60%
Ultimate elongation, initial, percent of minimum, ASTM D412	175%
Ultimate elongation after oven aging as percent of initial, minimum, ASTM D573	70%
Hardness, Shore A, ASTM D2240	75 ± 5
Hardness change Shore A, after oven aging, ASTM D573	7
Compression set as maximum percent of original, after oven aging, ASTM D395	40%
Low-temperature compression set as maximum percent of original, ASTM D1229	60%
Tear strength, pounds per inch	160 lb/in. 28 kn/m

*Dimensions and tolerances shall be as specified by the manufacturers for the specific standpipe or reservoir requirements.

3. Chemical resistance. The sealant shall be chemically resistant without extraction to water and shall not swell or degrade under normal water-storage conditions.

4. Material specification. The sealant shall be acceptable for use on food-contact surfaces.

5. Primers for sealant. Some sealant materials require the use of a primer on metal or glass for maximum adhesion. Most of these primers contain a volatile solvent. After evaporation of the solvent, the primer shall comply with the requirements of Sec. 2.10.2, item 4.

SECTION 3: GENERAL DESIGN

Sec. 3.1 Types of Joints

3.1.1 *Bolted joints.* All vertical, horizontal, shell-to-roof, and shell-to-bottom plates or sheets shall be field bolted. Bolt holes shall be shop punched or drilled for field assembly. The bolted joints between roof, shell, and bottom sheets and plates that are required to contain water or to be weathertight shall be sealed with suitable gasket material, sealant, or gasket material and sealant as required to make a watertight joint (see Sec. 2.10).

3.1.1.1 It is standard practice for field-assembled tanks to require fit-up alignments. This is acceptable, and the manufacturer's erection procedures shall be followed.

3.1.2 *Welded joints.* Welding may be used to join shop-fabricated subassemblies that are subsequently bolted into place in the field.

Sec. 3.2 Design Loads

The following loads shall be considered in the design of tank structures and foundations.

Copyright by the American Water Works Association
Wed Feb 02 02:15:40 2005

3.2.1 *Dead load.* Dead load shall be the estimated weight of all permanent construction and fittings. The unit weights used shall be 490 lb/ft^3 (7,849.1 kg/m^3) for steel and 144 lb/ft^3 (2,306.7 kg/m^3) for concrete.

3.2.2 *Water load.* Water load shall be the weight of all of the liquid when the tank is filled to top capacity level. Unit weight used for water shall be 62.4 lb/ft^3 (1,000 kg/m^3).

3.2.3 *Roof design loads.*

3.2.3.1 Snow load. Snow load shall be a minimum of 25 lb/ft^2 (1,200 Pa) on the horizontal projection of the tank for surfaces having a slope of 30° or less with the horizontal. For surfaces with greater slope, the snow loads shall be neglected. The snow load may be reduced when the tank is located where the lowest one-day mean low temperature is +5°F (–15°C) or warmer, and local experience indicates that a lesser load may be used.

3.2.3.2 The minimum roof-design live load shall be 15 lb/ft^2 (720 Pa). The roof plates or sheets may deflect between structural supports in order to support load.

3.2.4 *Wind load.* Wind pressure shall be assumed to be 30 lb/ft^2 (1,400 Pa) on vertical plane surfaces, 18 lb/ft^2 (860 Pa) on projected areas of cylindrical surfaces, and 15 lb/ft^2 (720 Pa) on projected areas of conical and double-curved plate surfaces. These quantities are based on a wind velocity of 100 mph (44.7 m/second). For structures designed for wind velocities of more than 100 mph (44.7 m/second), all aforementioned unit pressures shall be adjusted in proportion to the square of the velocity. When a sliding check for an unanchored tank is specified, a coefficient of friction equal to the tangent of 30 degrees is assumed. The total wind shear force $\leq W$ (tan 30°).

Where:

W = total weight of tank shell, floor, and roof

3.2.5 *Earthquake load.* Structures located in zones 1, 2A, 2B, 3, or 4 shall be designed for seismic loads as defined in Sec. 12 of this standard (for exception, see Sec. 3.2.5.2).

3.2.5.1 Structures located in zone 0 do not require design for earthquake resistance.

3.2.5.2 The purchaser may specify that earthquake design is not required on structures located in zone 1.

3.2.6 *Platform and ladder load.* A vertical load (and only one such load in each case) shall be applied as follows: 1,000 lb (453.6 kg) to each platform; 500 lb (226.8 kg) to any 10 ft^2 (0.93 m^2) area on the tank roof; 500 lb (226.8 kg) on each vertical section of the ladder. All structural parts and connections shall be properly proportioned to withstand such loads. The aforementioned load need not be combined with the snow load specified in Sec. 3.2.3, but shall be combined with the dead load. The platform and roof plating may deflect between structural supports in order to support the loading.

Sec. 3.3 Design Criteria

With the exception of other criteria specifically provided for elsewhere in this standard, the structural design of all standpipes and reservoirs shall be in compliance with the following:

1. AISI SG-671.
2. AISC S335.

Copyright by the American Water Works Association
Wed Feb 02 02:15:40 2005

Sec. 3.4 Tank Shell

In the design of the tank shell, the hydrostatic water pressure at the lower edge of each ring of sheets or plates in the tank shell shall be assumed to act undiminished on the entire area of the ring.

3.4.1 *Shell thickness.* When the net tensile stress governs, the thickness of cylindrical shell plates stressed by pressure of the tank contents shall be calculated by the formula*

$$t = \frac{2.6HDSG}{f_t(S-d)} \qquad \text{(Eq 1)}$$

Where:

t = shell plate thickness, in inches
H = height of liquid from the top capacity line just to overflow to the bottom of the shell course being designed, in feet
D = tank diameter, in feet
S = bolt spacing in line perpendicular to line of stress, in inches
G = specific gravity of liquid (1.0 for water)
f_t = allowable tensile stress, in pounds per square inch (Sec. 3.5.3)
d = bolt-hole diameter, in inches

3.4.2 *Compressive stress.* The allowable compressive stress in each ring of sheets or plates under wind or earthquake loading combined with dead load shall be determined by the formula

$$f_s = 15,000\left(\frac{2}{3}\right)\left(100\frac{t}{R}\right)\times\left[2-\left(\frac{2}{3}\right)\left(100\frac{t}{R}\right)\right] \le 15,000 \qquad \text{(Eq 2)}$$

Where:

f_s = allowable compressive stress, in pounds per square inch
t = shell thickness, in inches
R = shell radius, in inches

3.4.3 *Allowable stresses increased by one third.* The allowable stresses may be increased by one third when produced by wind or seismic loading acting alone or in combination with the design dead and water loads, provided the required section computed on this basis is not less than that required for the design dead and water load computed without the one-third stress increase.

*The equations shown throughout this standard are currently for use with the inch-pound system of units only. Metric equivalents are being developed by the Steel Elevated Tanks, Standpipes, and Reservoirs Committee and will be published in the next update of this standard.

Sec. 3.5 Bolted Joints

In the design of bolted joints, the effect of the gasket and sealant shall be neglected, provided the compressed thickness of the gasket or sealant does not exceed 1/16 in. (1.6 mm).

3.5.1 *Minimum spacing.* The center-to-center distance between bolts shall not be less than $2d$, where d is the diameter of the bolt, in inches (millimetres). The distance from the center of any bolt to an edge or seam shall not be less than $1.5d$. In no case shall the center-to-center or edge-to-center distance be less than

$$\frac{P}{0.6F_y t} \qquad \text{(Eq 3)}$$

Where:

P = force transmitted by the bolt, in pounds
F_y = published yield strength of the sheet or plate, in pounds per square inch
t = thickness of the thinner sheet, in inches

3.5.2 *Multiple bolt lines.* When multiple bolt lines are used, the effective net section area shall not be taken as greater than 85 percent of the gross area.

3.5.3 *Tension on the net section.* The tensile stress on the net section of a bolted connection shall not exceed the lesser of the values determined by the following formulas:

$$f_t = 0.6F_y(1.0 - 0.9r + 3rd/s) \leq 0.6F_y \qquad \text{(Eq 4)}$$

or

$$f_t = 0.40F_u \qquad \text{(Eq 5)}$$

Where:

f_t = allowable tensile stress, in pounds per square inch
F_y = published yield strength of the sheet material, in pounds per square inch
r = force transmitted by the bolt or bolts at the section considered, divided by the tensile force in the member at that section. If r is less than 0.2, it may be taken to equal zero
d = diameter of bolt, in inches
s = spacing of bolts perpendicular to line of stress, in inches
F_u = published ultimate strength of the sheet material, in pounds per square inch

3.5.4 *Hole bearing stress.* The hole bearing stress on the area $d \times t$ shall not exceed $1.35F_y$. The symbols d and F_y are as defined in Sec. 3.5.3; t is the thickness of the plate under consideration.

Copyright by the American Water Works Association
Wed Feb 02 02:15:41 2005

3.5.5 *Bolt shear.* Shear on bolts in live and dead loads shall not exceed the value as determined from the formula

$$f_v = \frac{F_u \times 0.6 \times 0.9}{2.2} = 0.25F_u \qquad \text{(Eq 6)}$$

Where:

f_v = allowable shear stress to the affected area, whether tensile stress area or gross area, in pounds per square inch
F_u = ultimate tensile stress of bolt, in pounds per square inch, as determined by the formula

$$F_u = \frac{F}{A_{ts}} \qquad \text{(Eq 6a)}$$

Where:

F = breaking load of the bolt as determined from tensile tests, in pounds
A_{ts} = tensile stress area as determined from the formula

$$A_{ts} = 0.7854\left(d - \frac{0.9743}{n}\right)^2 \qquad \text{(Eq 6b)}$$

Where:

d = nominal diameter of the bolt, in inches
n = number of threads per inch

3.5.6 *Bolt tension.* The tensile stress on bolts, other than anchor bolts, shall not exceed the lesser of the following:

$$f_t = 0.6F_y \qquad \text{(Eq 7)}$$

or

$$f_t = \frac{F_u}{2.2} \qquad \text{(Eq 8)}$$

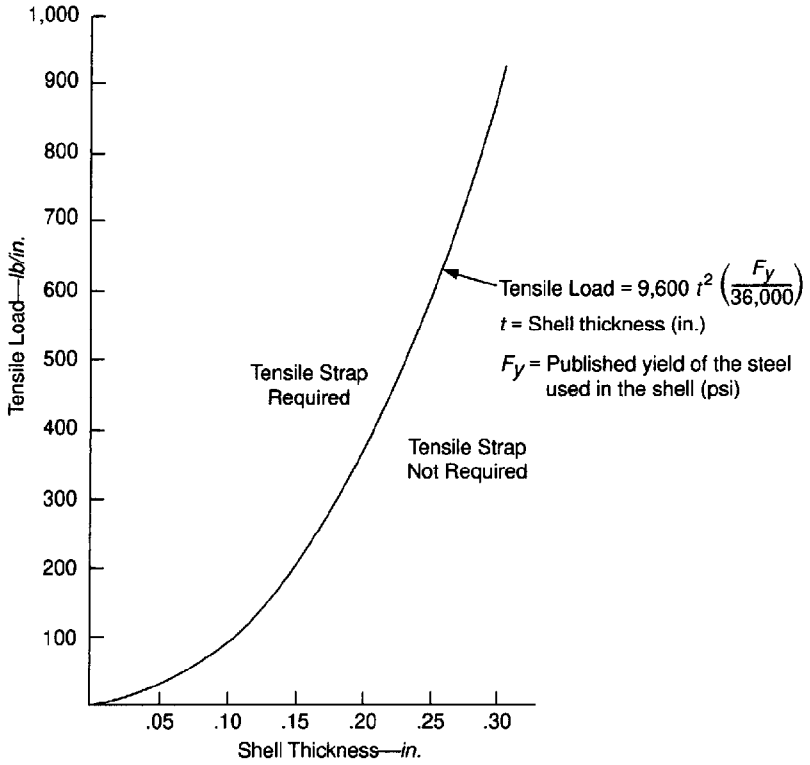
The symbols in these expressions are as previously defined in this section, following Eq 5.

When tensile straps are required in a butt-flanged connection, they shall be designed in accordance with Figure 1.

Sec. 3.6 Weld Design Values

3.6.1 *Structural joints.* Welded structural joints shall be proportioned so that the stresses on a section through the throat of the weld, exclusive of weld

Copyright by the American Water Works Association
Wed Feb 02 02:15:41 2005



NOTE: This chart is applicable only to tanks with formed flange connections having $^1/_2$-in. (12.7-mm) diameter bolts on 2-in. (50.8-mm) centers at a bolt circle 2 in. (50.8 mm) larger than the shell OD. No increase in allowable loads is permitted when using this chart.

Figure 1 Tensile straps aid in transferring vertical loads across horizontal joints

reinforcement, do not exceed the following percentages of the allowable working tensile stress of the structural material joined.

3.6.1.1 Groove welds. Tension, 85 percent; compression, 100 percent; shear, 75 percent.

3.6.1.2 Fillet welds. Transverse shear, 65 percent; longitudinal shear, 50 percent.

NOTE: Stress in a fillet weld shall be considered as shear on the throat, for any direction of the applied load. The throat of a fillet weld shall be assumed as 0.707 times the length of the shorter leg of the fillet weld having a flat or slightly convex profile.

Sec. 3.7 Top and Intermediate Shell Girders

3.7.1 *Top girder.* A tank without a roof shall have a top girder or angle having a minimum section modulus as determined by the formula

$$S = \frac{HD^2}{10,000}\left(\frac{V}{100}\right)^2 \qquad \text{(Eq 9)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:15:41 2005

Where:

S = minimum required section modulus, in cubic inches, of the top angle or girder, including a portion of the tank shell for the allowable distance below as specified in the introductory paragraph of Sec. 3.3, and, if applicable above, the ring attachment to the shell
H = height of the cylindrical portion of the tank shell, in feet
D = tank diameter, in feet
V = wind velocity, greater than 100 mph

3.7.1.1 The total vertical leg of the top girder or angle may be used in the computations, provided that the vertical leg width does not exceed the width-to-thickness ratios set forth in Sec. 3.3.

3.7.2 *Intermediate girders.* The following formula shall be used to determine whether intermediate girders are required between the roof or top girder and the bottom:

$$h = \frac{10.625(10)^6 t}{P(D/t)^{1.5}} \qquad \text{(Eq 10)}$$

Where:

h = vertical distance between the intermediate wind girder and the top angle of the shell or the top wind girder of an open-top tank, in feet
P = wind pressure, in pounds per square foot. This shall be assumed to be 18 unless the wind velocity is specified to be greater than 100 mph, in which case

$$P = 18\left(\frac{\text{wind velocity, in mph}}{100}\right)^2 \qquad \text{(Eq 10a)}$$

D = tank diameter, in feet
t = average shell thickness for the vertical distance h, in inches

3.7.2.1 In determining the maximum height of unstiffened shell, an initial calculation shall be made using the thickness of the top shell course. Additional calculations shall be based on the average thickness obtained by including part or all of the next lower course or courses, until the calculated h is equal to or smaller than the height of shell used in determining the average thickness. If h continues to calculate greater than the height of the shell used in determining the average thickness, then no intermediate girder is required.

3.7.2.2 After establishing the location of the first intermediate girder, if required, repeat the procedure for additional intermediate girders, using the preceding intermediate girder as the top of the tank. Locating the intermediate wind girder at the maximum spacing calculated by the preceding rules will usually result in a shell below the intermediate wind girder having a greater stability against wind loading than the shell above the intermediate girder. The girder may be located at a spacing less than the maximum spacing, but the lower shell must be checked for adequacy against the maximum wind pressure, as previously described or in the following alternative subparagraphs.

Copyright by the American Water Works Association
Wed Feb 02 02:15:41 2005

1. Change the width W of each shell course into a transposed width W_{tr} of shell course, having a uniform thickness, by the following relationship:

$$W_{tr} = W\left(\frac{t_{uniform}}{t_{actual}}\right)^{2.5} \quad \text{(Eq 11)}$$

Where:

$t_{uniform}$ = uniform thickness into which the entire shell will be transformed
t_{actual} = actual thickness of the plate course being transformed

2. The sum of the transposed width of each course will give the height of an equivalent transformed shell. For equal stability above or below the intermediate wind girder, the girder should be located at the mid-height of the transformed shell. The location of the girder on the transformed shell shall be transposed to the actual shell by the foregoing thickness relationship, using the actual thickness of the shell course on which the girder will finally be located and all actual thicknesses above this course.

3.7.2.3 When intermediate girders are required, they shall be proportioned in accordance with the formula

$$S = \frac{hD^2}{10{,}000} \times \left(\frac{V}{100}\right)^2 \quad \text{(Eq 12)}$$

Refer to Sec. 3.7.1 and 3.7.2 for an explanation of these symbols.

Sec. 3.8 Roof Supports

Roof supports or stiffeners, if used, shall be designed in accordance with the current specifications of AISC (ASD), with the following stipulations or exceptions:

1. The roof sheet will provide the necessary lateral support of roof rafters from the friction between the roof plates and rafter compression flange, with the following exceptions:
   a. Trusses and open-web joists used as rafters.
   b. Rafters having a nominal depth greater than 15 in. (381 mm)
   c. Rafters having a slope greater than 2 in 12.
2. The roof rafter and purlin depth may be less than fb/600,000 times the span length, provided the roof slope is ¾ in 12 or greater. The symbol fb is the bending unit stress (actual), equal to the bending moment divided by the section modulus of the member.
3. The maximum slenderness ratio L/r for the column supporting rafters shall be 175. L is the laterally unsupported length of the column, in inches, and r is the least radius of gyration, in inches. Columns supporting roofs shall be designed as secondary members.
4. Roof trusses shall be placed above the maximum water level in climates where ice may form.
5. Roof rafters shall be placed above the top capacity level. No part shall project below the top capacity level.

Copyright by the American Water Works Association
Wed Feb 02 02:15:42 2005

6. The maximum spacing between roof supports shall be determined by the formula

$$L = \sqrt{\frac{288F_y t^2}{W}} \leq 60 \qquad \text{(Eq 13)}$$

Where:

L = maximum spacing, in inches
F_y = published yield strength of the roof sheet material, in pounds per square inch
t = roof sheet thickness, in inches
W = roof dead load plus live load acting on roof surface, in pounds per square foot

Sec. 3.9 Steel Thickness

Steel thicknesses shall comply with the following:

1. Sheets on roofs having a slope of 1 in 2.75 or greater, for which the tank diameter does not exceed 35 ft (10.7 m), shall have a minimum thickness of 0.070 in. (1.8 mm).

2. Sheets on roofs having a slope less than 1 in 2.75, regardless of tank diameter, shall have a minimum thickness of 0.094 in. (2.4 mm).

3. The minimum thickness of the bottom sheets shall be 0.094 in. (2.4 mm).

4. The maximum thickness of shell plates shall be ⅜ in. (9.5 mm); the minimum thickness shall be 0.094 in. (2.39 mm).

5. The sheet thicknesses in ANSI/AWWA D103 designs are based on the criteria of hydraulic, wind, and seismic loadings with applicable bolted-joint efficiencies.

Sec. 3.10 Foundation Bolts

Foundation anchor bolts may be either upset or not upset and shall comply with the material requirements stated in Sec. 2.2.2. Anchor bolts shall be designed to resist the maximum uplift force. Allowable stresses may be increased as permitted in Sec. 3.4.3. The minimum anchor bolt diameter shall be ¾ in. (19.1 mm) and all anchor bolts shall be galvanized. The allowable tensile stress (F_t) shall be as follows based upon the gross (nominal) area of the bolt. They shall be proportioned for the maximum possible uplift, using the tensile stress area (Sec. 3.5.5) of the thread or the un-upset rod diameter, whichever is smaller, and 70 percent of the allowable tensile stress from Sec. 3.5.6. In no event should anchor bolts be less than ¾ in. in diameter. Foundation bolts may extend to within 3 in. of the bottom of the pier, but not necessarily more than far enough to develop the maximum uplift. Foundation bolts shall terminate in a right-angle hook, bend, head, or washer plate. The bond for plain-rod foundation bolts shall be calculated using the following formula:

$$F_t = 0.33F_u$$

Where:

F_u = minimum tensile strength of the bolt, in pounds per square inch

Copyright by the American Water Works Association
Wed Feb 02 02:15:42 2005

The tensile capacity of the threaded portion of an upset rod shall be larger than the body area times $0.6 F_y$, where F_y equals minimum yield strength of the bolt, in pounds per square inch. Anchor bolts may extend to within 3 in. (76.2 mm) of the bottom of a pier or footing, but not necessarily more than required to develop the maximum tension. Anchor bolts shall terminate in a right-angle hook, bend, head, or washer plate. The bond for plain-rod anchor bolts, in addition to the pullout resistance of the hook, bend, head, or washer plate, shall be calculated by the formula

$$U = \frac{4.8\sqrt{f'_c}}{d \times 2} \leq 160 \qquad \text{(Eq 14)}$$

Where:

U = unit bond stress, in pounds per square inch
f'_c = concrete compressive strength, in pounds per square inch
d = diameter of the anchor bolts, in inches

3.10.1 *Bolt projection.* The threaded ends of foundation anchor bolts shall project 2 in. (50.8 mm) above the nominal level of the tops of the foundation anchor bolt nuts to provide for variations in the foundation elevations. Lock nuts shall be provided or the threaded ends of anchor bolts shall be peened to prevent loosening of anchor nuts.

Sec. 3.11 Reinforcement Around Openings

All welded or bolted connections greater than 4 in. (101.6 mm) in diameter in the tank shell and other locations that are subject to hydrostatic pressure, where the thicknesses are established in accordance with the design criteria given in Sec. 3.3, shall be reinforced. The reinforcement may be the flange of a fitting, an additional ring of metal, a thicker plate, or any combination of these.

3.11.1 *Tank shell.* The amount of reinforcement for an opening in the tank shell shall be computed as follows:

The minimum cross-sectional area of the reinforcement shall not be less than the product of the maximum dimension of the hole cut in the tank shell and any bolt holes in the line perpendicular to the direction of the maximum stress and the required shell thickness. The cross-sectional area of the reinforcement shall be measured perpendicular to the direction of maximum stress coincident with the maximum dimension of the opening (100 percent reinforcement). All effective reinforcement shall be made within a distance equal to the maximum dimension of the hole in the shell. The direction of reinforcement shall be perpendicular to the maximum stress. The reinforcement shall be in either direction from the centerline of the shell opening.

3.11.2 *Fittings.* In the computation of the net reinforcing area of a fitting having a neck (such as a boilermaker's flange or a manhole saddle), the following portions of the neck may be considered as part of the area of reinforcement.

1. That portion extending outward from the outside surface of the shell for a distance equal to four times the neck wall thickness or, if the neck wall thickness is not uniform within that distance, to the point of transition.
2. That portion lying within the shell thickness.
3. If the neck extends inwardly, that portion extending inward from the inside surface of the shell for a distance as specified in item 1 above.

Copyright by the American Water Works Association
Wed Feb 02 02:15:42 2005

STD.AWWA D103-ENGL 1997 ■ 0783350 0505484 3T4 ■

3.11.2.1 The aggregate strength of the weld attaching a fitting to the shell or any intervening reinforcing plate, or both, shall at least equal the proportion of the forces passing through the entire reinforcement that is computed to pass through the fitting.

3.11.2.2 The aggregate strength of the weld attaching any intervening reinforcing plate to the shell shall at least equal the proportion of the forces passing through the entire reinforcement that is computed to pass through the reinforcing plate.

3.11.2.3 The attachment weld joining the flanged fitting or reinforcing plate to the shell shall be considered effective along the outer periphery only for the parts lying outside of the area bounded by parallel lines drawn tangent to the shell opening perpendicular to the direction of maximum stress. The outer peripheral welding, however, shall be applied completely around the reinforcement. All of the inner peripheral weld shall be considered effective. The outer peripheral weld shall be of a size equal to the thickness of the shell or reinforcing plate, whichever is less.

3.11.2.4 Manhole necks, nozzle necks, reinforcing plates, and shell openings that have sheared or oxygen-cut surfaces shall have uniform and smooth surfaces, with the corners rounded, except where these surfaces are fully covered by attachment welds.

3.11.2.5 Flange unions.

3.11.2.5.1 Piping flanges shall conform to the requirements given within this standard, except that, if specified by the purchaser, alternative types having equivalent strength, tightness, and utility may be furnished.

3.11.2.5.2 Except as otherwise provided in Sec. 3.11.2.5.1, bolted piping flanges shall be attached by bolts or bolt studs, and shall conform to the following:

1. Flanges shall be furnished in the sizes given in Table 2, as specified by the purchaser, and shall conform to the provisions of Table 2 and Figure 2.
2. The inner flange shall be provided with bolt-head or bolt-stud nut retainers.
3. The length of thread shall conform to the requirements of Table 2. In all other respects, the threads shall conform to the requirements of API 6A.

3.11.2.5.3 When bolted piping flanges conforming to Table 2 and Figure 2 are furnished, the tank members shall be drilled for flange attachment in accordance with the following stipulations:

1. The bolt-circle diameter and the number of bolt holes shall be as shown in Table 2 and Figure 2.
2. Bolt-hole sizes shall be optional with the manufacturer, but shall conform with the bolt-fit tolerance as shown in Table 2.
3. Flange bolt holes shall straddle the radial centerlines on roofs and bottoms, and vertical centerlines on staves, except that for the 4-in. (101.6-mm) diameter, five-hole flange the odd hole shall be located on the centerline toward the center for the roof or the top of the sheet.

SECTION 4: SIZING OF STANDPIPES AND RESERVOIRS

Sec. 4.1 Standard Capacities

The standard capacities for standpipes and reservoirs shall be as published by the manufacturer and shall be calculated to the nearest 1,000 gal (m^3).

Sec. 4.2 Shell Heights for Standpipes

The purchaser shall specify the required shell height for standpipes in accordance with the manufacturer's modular sizes.

Sec. 4.3 Diameters for Reservoirs

The purchaser shall specify the required reservoir diameter, with an allowable variation to conform with the manufacturer's standard modular sizes and capacity.

SECTION 5: ACCESSORIES FOR STANDPIPES AND RESERVOIRS

Sec. 5.1 Shell Manholes

One manhole, unless otherwise specified, shall be provided in the first ring of the tank shell at a location to be designated by the purchaser. In tanks with one manhole, a sheet opposite the manhole may be removed for additional ventilation if required for inspections or recoating. If any manhole cover weighs more than 50 lb (22.7 kg), a hinge or davit shall be provided.

5.1.1 *Size and shape.* Manholes may be either circular, 24 in. (610 mm) in diameter; square, 24 in. (610 mm) × 24 in. (610 mm); or elliptical, 18 in. (457 mm) × 22 in. (558.8), minimum size. Flush rectangular manholes with a minimum length of 24 in. (610 mm) in the shortest direction and a maximum length of 48 in. (1,219 mm) in the longest direction are also acceptable. Cutouts for rectangular manholes must have a minimum 6 in. (152 mm) radius at the corners.

5.1.2 *Reinforcing.* The shell plate where the manhole is located shall be reinforced to comply with Sec. 3.11, and all portions of the manhole, including the bolting, the cover, and reinforcement of the neck, shall be designed to withstand the weight and pressure of the tank contents.

Sec. 5.2 Pipe Connections

The pipe connections shall be of the size specified by the purchaser. They are usually attached to the tank bottom. Point of attachment shall be designated by the purchaser (see foreword, Sec. III.C, item 5).

5.2.1 *Silt stop.* If a removable silt stop is required, it shall be at least 4 in. in height, and the fitting or piping connection shall be flush with the tank floor when the stop is removed. If a removable silt stop is not required, the fitting or connecting pipe, or both, shall extend above the floor by at least 4 in.

5.2.2 *Shell connections.* Shell connections are permitted, provided the purchaser makes adequate provisions to protect the pipe from freezing and provides adequate pipe flexibility to account for shell rotation and deflections of the shell when filled.

5.2.3 *Flexibility.* Sufficient piping flexibility to accommodate seismic movements and settlement in the piping system shall be provided to protect the connections.

Sec. 5.3 Overflow

The tank shall be equipped with an overflow of the type and size specified by the purchaser. If a stub overflow is specified, it shall project at least 12 in. beyond the

Copyright by the American Water Works Association
Wed Feb 02 02:15:43 2005

tank shell. If an overflow to ground is required, it shall be brought down the outside of the tank shell and supported at proper intervals with suitable brackets. The overflow to the ground shall discharge over a drainage inlet structure or a splash block. It shall terminate at the top in a weir box or other appropriate intake. A top stiffener shall not be cut or partially removed. The overflow pipe and intake shall have a capacity at least equal to the pumping rate as specified by the purchaser, with a water level not more than 6 in. (152.4 mm) above the weir. The overflow pipe shall terminate at the bottom with an elbow. If carbon steel is specified by the purchaser, the overflow pipe shall have screwed or welded connections if it is smaller than 4 in. (101.6 mm) in diameter, or flanged or welded connections if it is 4 in. (101.6 mm) in diameter or larger. The purchaser shall specify the maximum flow rate, in gallons per minute, for which the overflow shall be designed. Internal overflows are not recommended but may be provided if specified by the purchaser. The internal overflow pipe shall have a minimum thickness of ¼ in. (6.4 mm).

Sec. 5.4 Ladders

5.4.1 *Outside tank ladder.* The constructor shall furnish a tank ladder on the outside of the shell beginning 8 ft (2.4 m), or as specified, above the level of the tank bottom, and located to provide access to the roof manway. The minimum clear width of step surface for rungs shall be 16 in. (406.4 mm), and rungs shall be equally spaced not less than 11 in. (279.4 mm), nor more than 15 in. (381 mm), on center. The perpendicular distance from the centerline of the rungs to the tank wall shall not be less than 7 in. (177.8 mm). Rung size shall not be less than ¾ in. (19 mm) in diameter, or equivalent section. The maximum spacing of supports attaching the ladder to the tank shall not exceed 10 ft (3 m). The minimum design live load shall be 2 loads of 250 lb (113.4 kg), each concentrated between any two consecutive attachments to the tank. Each rung in the ladder shall be designed for a single concentrated load of 250 lb (113.4 kg), minimum. The design loads shall be concentrated at such a point or points as will cause the maximum stress in the structural ladder member being considered. Side rails may be of any shape having section properties adequate to support the design loads and providing a means of securely fastening each rung to the side rail so as to lock each rung to the side rails.

5.4.2 *Inside tank ladder.* Inside tank ladders are not recommended. If an inside ladder is required, it shall comply with the requirements of Sec. 5.4.1.

5.4.3 *Roof ladder.* Unless otherwise specified, the constructor shall furnish access to roof hatches and vents. Such access shall be reached from the outside tank ladder according to the following:

1. For slopes 5 in 12 or greater, a ladder or stairway shall be provided.
2. Slopes less than 5 in 12 and greater than 2 in 12 shall be provided with a single handrail and nonskid walkway.
3. Slopes 2 in 12 or less do not require a handrail or nonskid surface.

5.4.4 *Minimum requirements.* Minimum requirements for ladders, hatches, and so forth can be found in OSHA 29 CFR Part 1910, "Occupational Safety and Health Standards," General Industry Standards. NOTE: Regardless of the access protection provided to tank roof hatches and vents, weather conditions on tank roofs are extremely variable and workers and their supervisors are expected to exercise good judgment in matters of safety. Among other things, this may include the use of safety lines when windy, icing, or other hazardous conditions exist.

Copyright by the American Water Works Association
Wed Feb 02 02:15:43 2005

Sec. 5.5 Safety Devices

If a safety cage, rest platforms, roof-ladder handrails, ladder lock, anti-climb device, or other safety devices are required by federal or local laws or regulations, the purchaser shall so specify. None of these are recommended for use inside the tank.

Sec. 5.6 Roof Openings

5.6.1 *Ladder.* The manufacturer shall furnish a roof opening, which shall be placed near the outside tank ladder and which shall be provided with a hinged cover and a hasp for locking. The opening shall have a clear dimension of at least 24 in. (610 mm) in one direction and 15 in. (381 mm) in the other direction. The opening shall have either (1) a curb at least 4 in. (101.6 mm) in height, and the cover shall have a downward overlap of at least 2 in. (50.8 mm), or (2) a gasketed weathertight cover, in lieu of the 4-in. (101.6-mm) curb and 2-in. (50.8-mm) overlap. When a combined screened vent-manhole cover equipped with locking hasp is provided at the roof center opening, the ladder opening may be omitted.

5.6.2 *Roof center.* An additional opening, with a removable cover having an opening dimension or diameter of at least 20 in. (508 mm) and 4-in. (101.6-mm) minimum height neck, shall be provided at, or near, the center of the tank. In lieu of the 4-in. (101.6-mm) neck, a gasketed, weathertight cover is also acceptable.

Sec. 5.7 Vent

If the tank roof is of tight construction, a suitable vent shall be furnished above the maximum water level. The vent shall have a capacity to pass air so that at the maximum possible rate of the water, either entering or leaving the tank, excessive pressure will not be developed. The overflow pipe shall not be considered a tank vent.

WARNING: An improperly vented tank may cause external pressures to act on the tank, which will cause buckling even at a low pressure differential.

5.7.1 *Location.* Even if more than one vent is required, one tank vent shall always be located near the center of the roof. The vent shall be designed and constructed to prevent the ingress of birds or animals.

5.7.2 *Screening.* When governing health authorities require screening against insects, a pressure-vacuum screened vent or a separate pressure-vacuum relief mechanism shall be provided which will operate in the event that the screens frost over or become clogged with foreign material. The screens or relief mechanism shall not be damaged by the occurrence and shall return automatically to the operating position after the clogging is cleared.

NOTE: The purchaser should clean the screens and check the pallets or relief mechanism for operation at least once a year, but preferably each spring and fall.

Sec. 5.8 Additional Accessories and Exceptions

Any additional accessories required to be furnished shall be specified by the purchaser. Exceptions to the provisions of this section may be specified by the purchaser to suit special situations.

SECTION 6: WELDING

Sec. 6.1 General

The field assembly of all vertical, horizontal, shell-to-roof, and shell-to-bottom plates or sheets shall be by bolting. Welding shall be limited to the shop installation of nozzles, vents, manways, connections, and subassemblies. Field welding is to be kept to a minimum and used only after acceptance by the manufacturer and purchaser.

Sec. 6.2 Welds

All welds in the tank and structural members shall be made according to the minimum requirements of AWS. Manufacturers shall maintain a welder training program and shall be able to certify if requested that these welds were made by AWS qualified welders and inspected according to AWS standards. These welds are to be made to ensure complete fusion with the base metal, within the limits specified for each joint, in strict accordance with the following procedure.

6.2.1 *Weather conditions.* Welding shall not be performed when the surfaces of the parts to be welded are wet from rain, snow, or ice; when rain or snow is falling on such surfaces; or during periods of high winds, unless the welder or welding operator and work are properly protected. Welding shall not be done when the base metal temperature is less than 0°F (–17.8°C). When the base metal temperature is within the range 0°F–32°F (–17.8°C–0°C), the base metal within 3 in. (76.2 mm) of the place where welding is to be started shall be heated until it is warm to the touch.

6.2.2 *Peening.* Peening of weld layers may be used to prevent undue distortion. Surface layers shall not be peened.

6.2.2.1 Peening shall be performed with light blows from a power hammer using a blunt-nosed tool.

6.2.3 *Contour.* All welds that are to be grit blasted before coating should be rough ground to remove any high points prior to grit blasting. Welds that will not be grit blasted shall be ground to a smooth contour.

6.2.3.1 Undercutting of base metal in the plate adjoining the weld shall be repaired.

6.2.3.2 All craters shall be filled to the full cross section of the weld.

6.2.4 *Reinforcement.* The reinforcement of butt welds shall be as small as practicable, preferably not more than 1/16 in. (1.6 mm). In no case shall the face of the weld lie below the surface of the plates being joined.

6.2.5 *Gouging.* Gouging at the root of welds and gouging of welds to remove defects may be performed with a round-nosed tool or by arc or oxygen gouging.

6.2.6 *Cleaning between beads.* Each bead of multiple-pass weld shall be cleaned of slag and other loose deposits before the next bead is applied.

Sec. 6.3 Preparation of Surfaces to Be Welded

Surfaces to be welded shall be free from loose scale, slag, heavy rust, grease, paint, and any other foreign material except tightly adherent mill scale. A light film of weldable rust-preventive coating or compound may be disregarded. Such surfaces shall also be smooth, uniform, and free from fins, tears, and other defects that adversely affect proper welding. A fine film of rust adhering to cut or sheared edges after wire brushing need not be removed.

Copyright by the American Water Works Association
Wed Feb 02 02:15:44 2005

Sec. 6.4 Low-Hydrogen Electrodes

The use of low-hydrogen electrodes will be helpful when welding is performed at low temperatures. When the designated low-hydrogen covered electrodes are used, preheating of the steel is not required unless the metal temperature is 32°F (0°C) or lower. After filler metal has been removed from its original package, it shall be protected or stored so that its characteristics or welding properties are not affected. In the case of low-hydrogen electrodes, this means keeping the electrodes warm and dry up to the time they are removed from the rod-storage oven. Low-hydrogen electrodes shall be stored, and rebaked if necessary, in accordance with electrode conditioning recommendations contained in AWS A5.1.

Sec. 6.5 Undercuts and Penetration of Welds

Welds shall be examined visually for compliance with the following:

6.5.1 *Butt and lap joints subject to primary stress.* For butt and lap joints subject to primary stress due to weight or pressure of tank contents, there shall be complete joint penetration and no undercutting.

6.5.2 *Butt joint subject to secondary stress.* For butt joints subject to secondary stress, there shall be complete joint penetration and no undercutting.

6.5.3 *Lap joints subject to secondary stress.* For lap joints subject to secondary stress, the maximum undercut permitted shall be 12 ½ percent of the thinnest sheet measured at each edge of the weld.

Sec. 6.6 Cleaning of Welds

The manufacturer shall remove weld scale or slag, spatter, burrs, and other sharp or rough projections in a manner that will leave the surface suitable for the subsequent cleaning and coating operation. Weld seams need not be chipped or ground, provided they may be satisfactorily cleaned and coated.

SECTION 7: SHOP FABRICATION

Sec. 7.1 Straightening

Any required straightening of material shall be done by methods that will not damage the steel. Minor cold straightening is permitted. Cold straightening may be done by hammering, or preferably, by rolling or pressing. Heat may be used in straightening more severe deformations.

Sec. 7.2 Finish of Plate Edges—Welded Work

The plate edges to be bolted or welded may be universal mill edges or they may be prepared by shearing, machining, chipping, or by mechanically guided oxygen or plasma arc cutting. Edges of irregular contour may be prepared by oxygen or plasma arc cutting.

7.2.1 *Oxygen or plasma arc cutting.* When edges of plates are oxygen or plasma arc cut, the surface obtained shall be uniform and smooth and shall be cleaned of slag accumulations before welding. All cutting shall follow closely the lines prescribed.

7.2.2 *Shearing.* Shearing may be used for material ⅜ in. (9.5 mm) or less in thickness.

Copyright by the American Water Works Association
Wed Feb 02 02:15:44 2005

Sec. 7.3 Rolling

Plates and sheets shall be cold rolled or pressed to suit the curvature of the tank and the erection procedure.

Sec. 7.4 Double-Curved Plates

Plates and sheets that are curved in two directions may be pressed or rolled either cold or hot.

Sec. 7.5 Manufacturing Tolerances

7.5.1 *Tanks with horizontally flanged shell joints.* Parts fabricated and punched for tanks with horizontally flanged shell joints shall comply with the dimensions and tolerances of API 12B.

7.5.2 *Tanks with horizontally lapped shell joints.* The tolerance on bolt-hole spacing for tanks with horizontally lapped shell joints shall be ±1/32 in. (0.8 mm) between any two holes, measured in the flat before forming.

Sec. 7.6 Coatings

Bolted tanks are supplied with factory-applied coatings (refer to Sec. 10 for coatings).

Sec. 7.7 Shipping

All material shall be loaded, transported to the site, unloaded, and stored in such a manner as to prevent damage.

SECTION 8: ERECTION

Sec. 8.1 General

The manufacturer shall provide instructions for the erection of the tank, and the tank shall be erected in accordance with these instructions.

Sec. 8.2 Bolting

All bolts shall be located and installed in accordance with the instructions on erecting the tank provided by the manufacturer.

Sec. 8.3 Gasketing and Sealants

Gasketing and sealants or both shall be supplied by the manufacturer and installed between all joints in compliance with the erection instructions. The constructor shall exercise care in properly locating and installing any special gaskets (chime lap gaskets, tapered inserts, and so forth) supplied by the manufacturer.

Sec. 8.4 Coating Repair

The coating shall be visually inspected by the constructor and any damage to the factory-applied coatings shall be repaired in strict compliance with the manufacturer's recommendations (see Sec. 10.2).

Copyright by the American Water Works Association
Wed Feb 02 02:15:44 2005

Sec. 8.5 Cleanup

On completion of the erection, the constructor shall, if required by the purchaser's specifications, dispose of all rubbish and other unsightly material caused by the operations and shall leave the premises in as good a condition as found at the start of the tank erection.

SECTION 9: INSPECTION AND TESTING

Sec. 9.1 Shop Inspection

9.1.1 *Shop inspection.* The purchaser may, if specified, require shop inspection by a commercial inspection agency, the cost of which shall be paid by the purchaser. Shop inspection shall at a minimum consist of a visual inspection of the fabricating practices and operations to determine compliance with this standard.

9.1.2 *Mill-test reports.* When specified by the purchaser, copies of certified mill-test reports shall be furnished by the manufacturer. The manufacturer shall obtain copies of all mill-test reports.

9.1.3 *Coating thickness test data.* When specified, the manufacturer shall supply certified test data on the coating thickness.

Sec. 9.2 Testing

9.2.1 *Repair of leaks.* Any leaks found shall be repaired by the constructor. It is preferred that repair of joints be made while the water level is above the point being repaired. See the foreword, Sec. III.C, item 7, for recommendations on blinding and filling the tank, which is not covered by this standard.

9.2.2 *Holiday testing.* When specified, independent field holiday detection testing shall be performed on the interior coated surfaces below maximum water level in accordance with the manufacturer's recommendations.

Sec. 9.3 Disposal of Test Water

The purchaser shall provide a means of disposing of test water with a connection to the inlet pipe or drain pipe.

Sec. 9.4 Disinfecting

Regardless of the sequence used for testing the tank, it shall be disinfected after the final test and the tank may then be filled with potable water and placed into service. Disinfection shall not be the responsibility of the constructor or manufacturer unless otherwise specified by the purchaser (see ANSI/AWWA C652).

SECTION 10: COATINGS

Sec. 10.1 General

Bolted tanks are manufactured by several tank manufacturers and coated in their own facilities and shipped worldwide. The following generic systems are representative of those in general use. Equivalent generic systems, for which documentation consisting of test data, service history, and toxicological information

Copyright by the American Water Works Association
Wed Feb 02 02:15:45 2005

have been provided by the tank manufacturer, shall be considered for use in storage tanks under the provisions of this standard.

Sec. 10.2 Coating Repair

It shall be the responsibility of each tank manufacturer to provide a procedure for field repair and touch-up of damaged coatings.

Sec. 10.3 Galvanized Coatings

When hot-dip galvanized coatings are to be supplied, zinc metal suitable for immersion in drinking water shall be applied to the tank parts after fabrication in accordance with the recommended practice of the American Hot Dip Galvanizers Association* in compliance with ASTM A123 and ASTM A153.

Sec. 10.4 Glass Coatings

When glass fused-to-steel coatings are provided, the coatings shall be applied according to the tank manufacturer's recommendations. Glass coatings are to comply with the following.

10.4.1 *Surface preparation.* The steel shall be cleaned of all oils and lubricants. Mill scale and rust must be removed from the steel surface by grit blasting in accordance with SSPC SP10 or by pickling in compliance with SSPC SP8.

10.4.2 *Coatings.*

10.4.2.1 The steel is to be primed with applications of catalytic nickel oxide when tanks are fabricated from hot-rolled steel. Hot-rolled steel is susceptible to fish scaling, which is a hydrogen defect that can be controlled by applications of catalytic nickel oxide. Such a primer is necessary if both sides of hot-rolled steel are glass coated.

10.4.2.2 Glass coatings can be applied by wet spraying, flow coating, dipping, or electrophoretic deposition. The coating thickness shall be between 6 mils (0.15 mm) and 19 mils (0.48 mm).

10.4.2.3 The glass coating must be cured or fused to the steel by firing. This is most conveniently done in a furnace, but can be carried out by means of induction or resistance heating. The temperature should be above 1,200°F and preferably in the range of 1,450°F to 1,600°F.

10.4.3 *Inspection.* The coating shall be inspected for any visible defects or holidays. If severe conditions are encountered, a wet-pad resistance test should be used to determine the extent of microscopic defects on the tank interior surfaces only (Sec. 10.9).

Sec. 10.5 Thermoset Liquid Suspension Coatings

When thermoset liquid suspension epoxies are used, the coatings shall be applied according to the tank manufacturer's recommendations. Coatings are to comply with the following.

10.5.1 *Surface preparation.* Surface preparation shall comply with the following.

10.5.1.1 The steel shall be thoroughly cleaned by a wash-rinse followed immediately by hot air drying.

10.5.1.2 The steel shall then be grit blasted on both sides in accordance with SSPC SP10. The surface anchor pattern shall be a minimum of 1 mil (0.03 mm).

*American Hot Dip Galvanizers Association, 1000 Vermont Ave. N.W., Washington, DC 20005.

Copyright by the American Water Works Association
Wed Feb 02 02:15:45 2005

10.5.2 *Coatings.* The coatings are to be applied in compliance with the following.

10.5.2.1 Within 30 min of blast cleaning (Sec. 10.5.1.2), the interior surfaces of the tank shall receive one coat of amine-cured thermoset epoxy in strict accordance with the manufacturer's recommendations.

10.5.2.2 The exterior surfaces of the tank shall receive one coat of epoxy primer or equal as determined by the tank manufacturer.

10.5.2.3 The interior and exterior coatings (Sec. 10.5.2.1 and 10.5.2.2) shall be oven heated until the coats have a tacky finish, with partial thermal cross-linking.

10.5.2.4 The interior surfaces of the tank shall receive a second coat of amine-cured epoxy to provide a total of 5-mil (0.13-mm) minimum dry film thickness.

10.5.2.5 The exterior surfaces of the tank shall receive a finish coat of acrylic baking enamel and be thermally cured. Minimum dry film thickness shall be a total of 3 mils (0.08 mm).

10.5.2.6 The interior and exterior finish coats shall be oven-heated at 425°F–525°F (218.3°C–273.8°C) for a minimum of 10 min to completely thermal cross-link both thermoset coatings.

10.5.2.7 Exterior coatings may be modified by agreement between the purchaser and the tank manufacturer.

10.5.3 *Inspection.*

10.5.3.1 Inspection of interior. A representative sampling of interior coated surfaces shall be inspected and accepted by the tank manufacturer prior to shipment. The inspection shall include a nondestructive mil-thickness test (Mikrotest or equal), a holiday detection test (Tinker Razor or equal), and methyl ethyl ketone (MEK) solvent test consisting of 20 wipes or equal.

10.5.3.2 Inspection of exterior. A representative sampling of exterior coated surfaces shall be inspected and accepted by the tank manufacturer prior to shipment. The inspection shall include a nondestructive mil-thickness test (Mikrotest or equal).

Sec. 10.6 Thermoset Powder Coatings

When thermoset powder coatings are used, the coatings shall be applied according to the tank manufacturer's recommendations. Thermoset powder coatings are to comply with the following.

10.6.1 *Surface preparation.* The steel shall be steel-grit blasted on all sides in accordance with SSPC SP10.

10.6.2 *Application.* The coating is to be applied in compliance with the following.

10.6.2.1 After blast cleaning, the interior and exterior surfaces shall be dry-powder coated by electrostatic application with a powder coating.

10.6.2.2 The dry powder shall be deposited at a rate to yield 3 mil-minimum dry film thickness.

10.6.2.3 The surfaces shall be oven cured in accordance with the dry-powder coating manufacturer's standard practice and specifications.

10.6.3 *Inspection.*

10.6.3.1 Inspection interior. A representative sampling of interior coated surfaces shall be inspected and accepted by the tank manufacturer prior to shipment. The inspection shall include a nondestructive mil-thickness test (Mikrotest or equal), a holiday detection test (Tinker Razor or equal), and methyl ethyl ketone (MEK) solvent test consisting of 20 wipes or equal.

Copyright by the American Water Works Association
Wed Feb 02 02:15:45 2005

10.6.3.2 Inspection exterior. A representative sampling of exterior coated surfaces shall be inspected and accepted by the tank manufacturer prior to shipment. The inspection shall include a nondestructive mil-thickness test (Mikrotest or equal).

Sec. 10.7 Marking

All of the tank components shall be given a piece mark number for ease of assembly. In lieu of this, the tank manufacturer's standard practice may be used.

Sec. 10.8 Protection

All coated parts shall be protected from damage during shipment.

Sec. 10.9 Holiday Testing

All holiday tests shall be nondestructive and shall use an electric DC meter and a wet sponge device. The maximum voltage of the meter shall be 67.5 volts. The sponge shall be dipped in tap water as required to keep it uniformly damp, not soaked or dry. No "conductive" or "wetting" additives shall be used in the tap water. Refer to the tank manufacturer's recommendations for setting, testing, and operation of the meter by a trained technician.

SECTION 11: FOUNDATION DESIGN AND CONSTRUCTION

Sec. 11.1 General Requirements

The foundations are important because unequal settlement changes the distribution of stresses in the structure and may cause leakage or buckling of the plates.

11.1.1 *Foundation plans.* The manufacturer (or constructor) is not required to furnish foundation plans unless specified by the purchaser. Should the purchaser require foundation plans by the manufacturer or constructor, see Sec. II.D and III.C of the foreword for additional information. Anchor bolts, when required, shall be designed and furnished by the manufacturer.

11.1.2 *Foundation installation.* Foundations may be installed by either the purchaser or the constructor (see the foreword, Sec. II.D and III.C). The earth around the foundation shall be regraded sufficiently to permit efficient work during tank erection and to prevent ponding of water in the foundation area. The tops of the foundations shall be accurately located at the proper elevation.

11.1.3 *Water load.* Water load as defined in Sec. 3.2.2, shall be considered as live load as defined by ACI 318 (see Sec. 11.6). The appropriate factors for all live loads shall be used in foundation design.

Sec. 11.2 Soil-Bearing Value

The purchaser shall specify the allowable soil-bearing pressure using an appropriate factor of safety (Sec. 11.3). However, in no case shall the specified bearing pressure exceed that which would cause intolerable settlements and impair the structural integrity of the tank.

11.2.1 *Soil investigation.* A soil investigation shall be provided by the purchaser to determine the following:

1. The presence or absence of rock, old excavation, or fill.
2. Whether the site is a suitable place on which to build the structure.

Copyright by the American Water Works Association
Wed Feb 02 02:15:45 2005

3. The classification of soil strata, after appropriate sampling.
4. The type of foundation that will be required at the site.
5. The elevation of groundwater, and whether dewatering is required.
6. The bearing capacity of the soil, and the depth at which footings must be founded.
7. Whether piling will be required for support of foundations, and the length of such piling.
8. The elevations of the existing grade and other topographical features that may affect the foundation design or construction.
9. The homogeneity and compressibility of the soils across the tank site, so that the possibility of total and differential settlement of the structure may be evaluated.

Sec. 11.3 Factor of Safety

The following minimum factors of safety shall be used in determining the allowable soil-bearing pressure. The ultimate bearing capacity should be based on sound principles of geotechnical engineering. See the foreword, Sec. III.C, item 10, for additional information.

11.3.1 *Standpipes and reservoirs.* A factor of safety of 3 shall be provided, based on calculated ultimate bearing capacity when all direct loads and wind are considered.

11.3.1.1 A factor of safety of 2.25 shall be provided, based on calculated ultimate bearing capacity when all direct loads and earthquake loads are considered.

Sec. 11.4 Foundations

All tanks shall be supported on a concrete ringwall, concrete slab, or structurally compacted granular berm as specified by the purchaser. The top of the foundation shall be a minimum of 6 in. (152.4 mm) above the finished grade, unless otherwise specified by the purchaser. Tanks that require anchor bolts shall be supported on a ringwall or a concrete slab.

11.4.1 *Types of foundations.* The tank foundation shall be one of the following types.

11.4.1.1 Type 1. Tanks supported on ringwalls. A sand or fine stone cushion at least 3 in. (76.2 mm) thick shall be provided above the earthen interior under the tank bottom. A 1-in. minimum space between the tank bottom and the top of the ringwall shall be filled with a nonshrink grout or a 1:1.5 cement-sand grout. The grout shall fill the entire space beneath the tank from the outside edge of the tank bottom to the cushion. In no case shall the width of grout placed under the tank bottom be less than 6 in. The top of the foundation shall be thoroughly saturated with water before grout is placed. The materials and labor for grouting shall be furnished by the constructor. In lieu of grout under the shell, the shell may be supported on a minimum ½-in. (12.7-mm)-thick cane-fiber joint filler meeting the requirements of ASTM D1751 if the foundation under the shell meets the tolerances of Sec. 11.6.1.

11.4.1.2 Type 2. Tanks supported on concrete slabs. A sand or fine stone cushion not less than 1 in. (25.4 mm) thick shall be provided between the flat bottom and the concrete slab foundation. In lieu of a cushion, the bottom may be supported on a minimum ½-in. (12.7-mm)-thick cane-fiber joint filler meeting the requirements of ASTM D1751. The tank shell shall be supported with grout or, alternatively, fiber joint filler if the foundation under the shell meets the tolerances of Sec. 11.6.1. When grouted, a 1-in. (25.4-mm) minimum space between the tank bottom and the top of

Copyright by the American Water Works Association
Wed Feb 02 02:15:45 2005

the concrete shall be filled with a nonshrink grout or a 1:1.5 cement-sand grout. The grout shall fill the entire space beneath the tank from the outside edge of the tank bottom to the cushion. In no case shall the width of grout placed under the tank bottom be less than 6 in. (152.4 mm). The top of the foundation shall be thoroughly saturated with water before grout is placed. The materials and labor for grouting shall be furnished by the constructor.

NOTE: When a steel base-setting ring is used in conjunction with a concrete slab, no grout or fiber joint filler is required (see Sec. 11.4.1.6 for Type 6 foundations).

11.4.1.3 Type 3. Tanks within ringwalls. Tanks may be placed on a cushion within a concrete ringwall. The cushion shall consist of a minimum of 6 in. (152.4 mm) of sand or fine stone. The inside of the ringwall is to be a minimum of ¾ in. (19 mm) outside the bottom plates of the tank. Adequate provisions for drainage inside the ringwall must be made.

11.4.1.4 Type 4. Tanks supported on granular berms. The berm shall be well-graded stone or gravel. The berm shall extend a minimum of 3 ft (0.9 m) beyond the tank shell and from there have a maximum slope of 1:1.5. The berm under the shell shall be level within ±⅛ in. (3.2 mm) in any 10 ft (3 m) of circumference and within ±½ in. (12.7 mm) in the total circumference. Adequate protection shall be provided to ensure against foundation washout.

11.4.1.5 Type 5. Tanks supported on granular berms with steel retainer rings. The berm shall be well-graded stone or gravel. The berm shall extend to the retainer ring. The size and coating of the steel retainer ring shall be specified by the purchaser and shall be a minimum of 12 in. (304.8 mm) from the shell or a sufficient distance to ensure berm stability under the shell in the event that the steel retainer ring is removed. The berm under the shell shall be level within ±⅛ in. (3.2 mm) in any 10 ft (3 m) of circumference and within ±½ in. (12.7 mm) in the total circumference.

11.4.1.6 Type 6. Tanks with base setting ring embedded in concrete slab. The base setting ring shall be supported on a ringwall foundation prior to placement of slab concrete. A minimum clear distance of 3 in. (76.2 mm) between the top of the slab and the bottom of the base setting ring shall be provided. The outside curb shall have a minimum width of 8 in. (203.2 mm), and its top shall be level within ±1 in. of the top of the slab. A minimum of one elastomer water stop shall be bonded to the inside base setting ring surface at a minimum distance of 2 in. below the top of the concrete slab. Shrinkage-reinforcing steel shall be used in the concrete slab adjacent to both the inside and the outside of the base setting ring in accordance with ACI 318. For concrete slabs supported on grade, the manufacturer shall provide specifications for the preparation of sub-base material, if required by the purchasers specifications (see foreword, Sec. III.C, item 11).

Sec. 11.5 Detail Design of Foundations

11.5.1 *Height above ground.* The tops of the concrete foundations shall be a minimum of 6 in. (152.4 mm) above the adjacent grade, unless otherwise specified by the purchaser.

11.5.2 *Minimum depth of foundations.* The minimum depth of foundations shall be determined from Figure 3. The extreme frost penetration depths in Figure 3 shall be the minimum depth of foundation below the ground line. Foundation depth shall be increased in localities where soil or other factors are favorable to deep frost penetration and may be reduced for piers resting on rock. Consult local records for

Copyright by the American Water Works Association
Wed Feb 02 02:15:46 2005

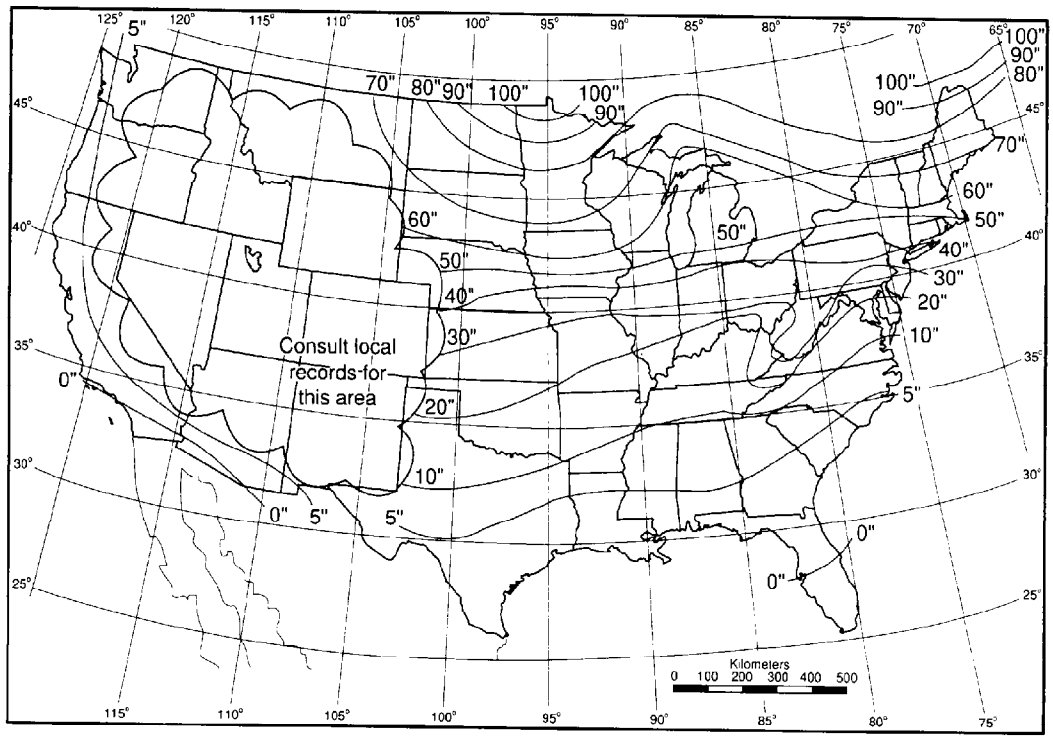

Figure 3 Extreme frost penetration—inches (based on state averages)

the extreme frost penetration in the circled area of Figure 3. Uplift or soil-bearing requirements may dictate greater depths. Minimum depth shall be 12 in. (304.8 mm).

11.5.3 *Size of top.* The tops of foundations shall project at least 3 in. beyond the tank shell. In base setting ring applications, the top of the foundation should project a minimum of 8 in. (203 mm) beyond the tank shell. The top corners shall be either neatly rounded or finished with a suitable bevel. When anchor bolts are required, the foundations shall extend at least 9 in. (228.6 mm) beyond the tank shell.

11.5.4 *Pile foundations.* If a pile-supported foundation is required, the purchaser shall specify the pile type and depth below existing grade to be used for bidding and design capacities for live and dead loads, including the weight of all soil above the footing, and for live and dead loads combined with wind or seismic loads or both.

Sec. 11.6 Concrete Design, Materials, and Construction

The design of the concrete foundations, the specifications for the cement and aggregate, and the mixing and placing of the aggregate shall be in accordance with ACI 318, except as may be modified in this section and the following subsections. Concrete work shall conform to all requirements of ACI 301, except as modified by agreement between the purchaser and constructor.

11.6.1 *Tolerances on concrete foundations.* Ringwalls and slabs, after grouting or before placing the cane-fiber joint filler, shall be level within ±⅛ in. (±3.08 mm) in any 30-ft (9.1-m) circumference under the shell. The levelness on the circumference shall not vary by more than ±¼ in. (6.4 mm) from an established plane. The tolerance on poured concrete before grouting shall be ±1 in. (25.4 mm).

Copyright by the American Water Works Association
Wed Feb 02 02:15:46 2005

11.6.2 *Finish.* The top portions of foundations, to a level 6 in. (152.4 mm) below the proposed ground level, shall be finished to a smooth form finish in compliance with ACI 301. Any small holes may be troweled over with mortar as soon as possible after the forms are removed.

11.6.3 *Anchor bolts.* It is the responsibility of the constructor to locate the anchor bolts within ¼ in. (6.35 mm) of the manufacturer's anchor bolt layout design.

11.6.4 *Base-setting ring.* If a base-setting ring is required, it is the responsibility of the constructor to level the setting ring within 1/16 in. (1.54 mm) of level and concentric within ¼ in. (6.35 mm). The constructor shall locate the manufacturer-supplied base-setting ring in conformance with the manufacturer's design.

Sec. 11.7 Backfill

For tanks with ringwall foundation, all topsoil, organic material, and undesirable material within the ringwall shall be removed and replaced with a controlled, load-bearing backfill specified by the designer of the foundation. The natural soils and load-bearing backfill within the ringwall shall be capable of supporting the tank bottom without general settlement or localized settlement causing breakdown of the tank bottom adjacent to the ringwall.

11.7.1 *Material and compaction.* Load-bearing backfill shall be suitable non-frozen material placed and compacted in uniform horizontal lifts to the degree of compaction required by the foundation design. The water load and ringwall height shall be considered in determining the required degree of compaction.

11.7.2 *Pipe cover.* Pipe cover shall be provided in compliance with Figure 4 unless local conditions dictate that more or less cover should be used.

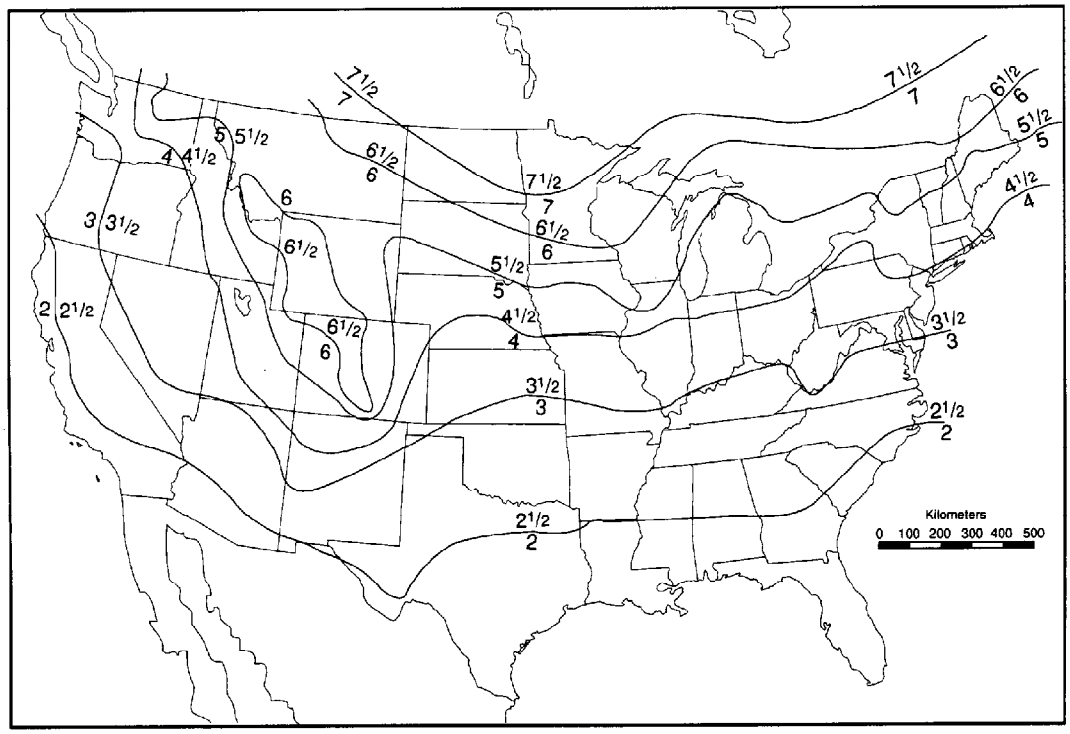

Figure 4 Recommended depth of pipe cover—feet above top of pipe

Wed Feb 02 02:15:46 2005

SECTION 12: SEISMIC DESIGN OF FLAT-BOTTOM WATER-STORAGE TANKS

Sec. 12.1 General

12.1.1 *Applicability.* This section shall be used as prescribed by Sec. 3.2.5.

12.1.2 *Tabulation form for seismic data.* A sample tabulation form for seismic data, for use by the purchaser, is included in Sec. 12.7. It is followed by an example to demonstrate the use of the form. The tabulation form for seismic loads shall be completed by the purchaser.

Sec. 12.2 Seismic Design Considerations

12.2.1 *Effective-mass method.* The design of ground-supported, flat-bottom tanks recognizes the reduction in seismic load due to the sloshing of the contained liquid. This design procedure is referred to as the effective-mass method. See the references in Sec. 12.8 for details of this design method.

12.2.2 *Anchored and unanchored tanks.* Flat-bottom tanks may be anchored or unanchored to resist earthquakes.*

12.2.2.1 Anchored tanks could be susceptible to tearing of the shell if anchorage is not properly designed. Care must be taken to ensure that anchor-bolt attachments are stronger than the anchor bolt. Experience shows that properly designed anchored tanks retain greater reserve strength to seismic overload than unanchored tanks. Anchorage shall be designed such that anchor bolts yield before the shell attachment fails.

12.2.2.2 Seismic resistance of an unanchored tank is related to the height-to-diameter ratio of the structure.

Sec. 12.3 Seismic Design Loads

The following design loads are based on a consistent probability of seismic disturbance in the United States. A use factor has been included based upon use and importance of the storage tank. Allowable stresses in this section apply only to loading conditions, which include seismic loads defined in this standard. Static load and wind conditions are covered by Sec. 3. Allowable stresses for anchor bolts shall conform to AISC (ASD) allowable stresses.

12.3.1 *Effective-mass procedure.* The effective-mass procedure considers two response modes of the tank and its contents: (1) the high-frequency amplified response to lateral ground motion of the tank shell and roof together with a portion of the liquid contents that moves in unison with the shell, and (2) the low-frequency amplified response of a portion of the liquid contents in the fundamental sloshing mode. The design requires the determination of the hydrodynamic mass associated with each mode and the lateral force and overturning moment applied to the shell resulting from the response of the masses to lateral ground motion.

*If an unanchored tank design is used, the maximum thickened bottom annulus width (radial direction) used to resist overturning shall be limited to 7 percent of the tank radius. For the maximum thickness of the bottom annulus, refer to Sec. 12.3.3.2. The tank must be anchored if these criteria cannot be met.

Wed Feb 02 02:15:47 2005

The base shear and overturning moment due to seismic forces applied to the bottom of the shell shall be determined in accordance with the following formulas:

Base shear:

$$V_{ACT} = \frac{18ZI}{R_w}[0.14(W_s + W_r + W_1) + SC_1W_2] \quad \text{(Eq 15)}$$

Overturning moment:

$$M = \frac{18ZI}{R_w}[0.14(W_sX_s + W_rH_t + W_1X_1) + SW_2X_2C_1] \quad \text{(Eq 16)}$$

Where:

V_{ACT} = actual lateral shear, in pounds
M = overturning moment applied to the bottom of tank shell, in foot-pounds or other consistent units
Z = zone coefficient from Figure 5 and Table 3
I = use factor from Table 6
R_w = force reduction coefficient from Table 4
W_s = total weight of tank shell bottom, and significant appurtenances in pounds. The bottom shall not be included in the calculation for overturning moment in Eq 16
X_s = height from the bottom of the tank shell to the center of gravity of the shell, in feet
W_r = total weight of the tank roof (including framing and knuckle) plus permanent loads, if any, as specified by the purchaser, in pounds. Only that portion of the roof that bears on the shell shall be considered for the overturning moment in Eq 16
H_t = total height of the tank shell, in feet
W_1 = weight of effective mass of tank contents that moves in unison with the tank shell, in pounds (Sec. 12.3.2)
X_1 = height from the bottom of the tank shell to the centroid of lateral seismic force applied to W_1, in feet (Sec. 12.3.2)
S = site amplification factor from Table 5. Assumed to be 1.5 unless otherwise specified by purchaser
W_2 = weight of effective mass of the first mode sloshing contents of the tank, in pounds (Sec. 12.3.2)
X_2 = height from the bottom of the tank shell to the centroid of lateral seismic force applied to W_2, in feet (Sec. 12.3.3)

C_1 is determined as follows:

For the condition where $T_w < 4.5$ seconds:

$$C_1 = \frac{1}{6T_w} \quad \text{(Eq 16a)}$$

Table 5 Site amplification factor S

	Soil Profile Type			
	A	B	C	D
Site Amplification Factor*	1.0	1.2	1.5	2.0

*The following is an explanation for the determination of the site amplification factor, which shall be supplied by the purchaser. Site effects on tank response shall be established based on the following four soil profile factors:

1. *Soil Profile Type A* is a profile with:

a. Rock of any characteristic, either shale-like or crystalline in nature. Such material may be characterized by a shear wave velocity greater than 2,500 ft/second (760 m/second).

b. Stiff soil conditions where the soil depth is less than 200 ft (61 m) and the soil types overlying rock are stable deposits of sands, gravels, or stiff clays.

2. *Soil Profile Type B* is a profile with deep, cohesionless or stiff clay conditions, including sites where the soil depth exceeds 200 ft (61 m) and the soil types overlying rock are stable deposits of sands, gravels, or stiff clays.

3. *Soil Profile Type C* is a profile with soft to medium-stiff clays and sands characterized by 30 ft (9.1 m) or more of soft to medium-stiff clay with or without intervening layers of sand or other cohesionless soils.

4. *Soil Profile Type D* is a profile containing more than 40 ft (12.2 m) of soft clay characterized by a shear wave velocity less than 500 ft/second (152.4 m/second).

In locations where the soil profile type is not known in sufficient detail to determine the soil profile type, soil profile type C shall be assumed.

Table 6 Use factor I^*

1.25	Sole supply Fire protection Multiple supply and fire protection
1.0	Multiple supply and no fire protection

*An I of 1.25 shall be used unless otherwise specified by the purchaser.

For the condition where $T_w \geq 4.5$ seconds:

$$C_1 = \frac{0.75}{T_w^2} \qquad \text{(Eq 16b)}$$

T_w = first mode sloshing wave period, in seconds, which is determined as follows:

$$T_w = K_p D^{1/2} \qquad \text{(Eq 16c)}$$

Where:

K_p = factor from Figure 6 for the ratio of tank diameter, in feet, to maximum depth of water, in feet, D/H, or other consistent units

D = tank diameter, in feet

Copyright by the American Water Works Association
Wed Feb 02 02:15:47 2005

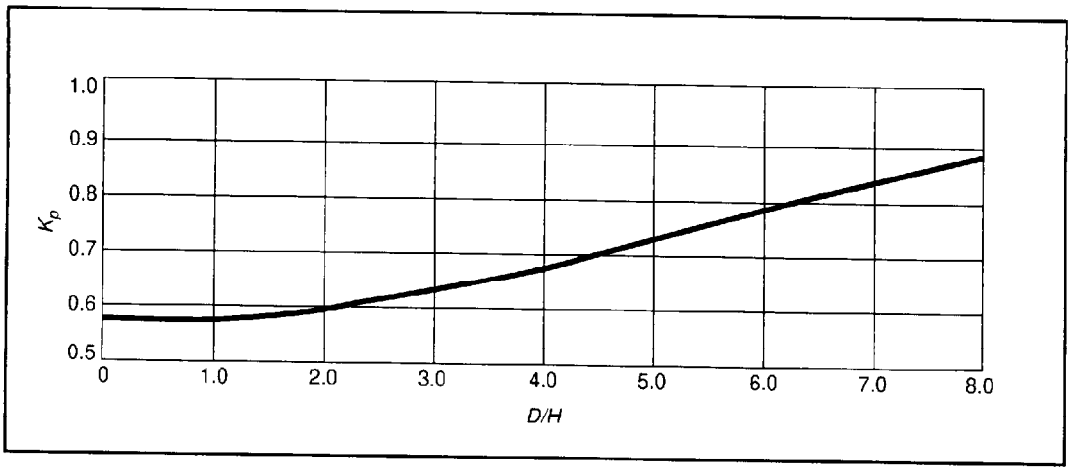

Figure 6 Curve for obtaining factor K_p for the ratio D/H

NOTE: The overturning moment determined by this formula is that applied to the bottom of the shell only. The tank foundation is subjected to an additional overturning moment due to lateral displacement of the tank contents. This may need to be considered in the design of some foundations, such as pile-supported concrete slabs.

12.3.2 *Effective mass of tank contents.*

12.3.2.1 The weight of the effective mass of the tank contents that moves in unison with the tank shell W_1 (Eq 15 and 16) and the weight of the effective mass of the first mode sloshing contents W_2 (Eq 15 and 16) may be determined by multiplying W_T (Eq 17) by the ratios W_1/W_T and W_2/W_T, respectively. These ratios may be obtained from Figure 7 for the ratio D/H,

Where:

W_T = total weight of tank contents, in pounds. This value is determined by the formula

$$W_T = 62.4GH\left(\frac{\pi D^2}{4}\right) = 49GHD^2 \qquad \text{(Eq 17)}$$

Where:

D = tank diameter, in feet
H = maximum depth of water in the tank, in feet
G = specific gravity (1.0 for water)

12.3.2.2 The heights X_1 and X_2 (Eq 16), from the bottom of the tank shell to the centroids of the lateral seismic forces applied to W_1 and W_2 (Eq 16), may be determined by multiplying H by the ratios X_1/H and X_2/H, respectively. These ratios may be obtained from Figure 8 for the ratio D/H.

12.3.2.3 The curves in Figures 7 and 8 are based on a modification of equations in "Nuclear Reactors and Earthquakes" (see Sec. 12.8, reference 1). Moment arms X_1 and X_2 are valid for tanks supported on ringwalls. For tanks supported on slabs, see reference 1 for additional overturning moment. Alternatively, W_1, W_2, X_1, and X_2 may

be determined by other analytical procedures based on the dynamic characteristics of the tank. Where response spectra* are used, the acceleration of the two masses shall replace the seismic coefficient as follows:

$$A_{impulsive}, \left[\frac{(A_i)}{R_F}\right], \text{ replaces } (0.14)\frac{18ZI}{R_w} \text{ (in g's)}$$

$$A_{convective}, \left[\frac{(A_c)}{R_F}\right], \text{ replaces } \frac{18ZIC_1S}{R_w} \text{ (in g's)}$$

Where:

g = acceleration due to gravity, which is 32.2 ft/second^2
R_F = reduction factor (see Sec. 12.4.1)

The spectral velocity is related to the convective acceleration as follows:

$$S_v = 5.125A_cT_w, \text{ in ft/second} \qquad \text{(Eq 18)}$$

or

$$S_v = 92.25\frac{C_1ZIST_w}{R_w}, \text{ in ft/second} \qquad \text{(Eq 19)}$$

Where:

S_v = spectral velocity, in feet per second
A_i = impulsive acceleration, in g's, determined from the response spectrum
A_c = convective acceleration, in g's, determined from the response spectrum
T_w = first mode sloshing wave period, in seconds

The other symbols are previously defined in Sec. 12.3.1.

12.3.3 *Resistance to overturning.*

12.3.3.1 Resistance to the overturning moment at the bottom of the shell may be provided by the weight of the tank shell, weight of roof reaction on shell, W_{rs}, and by the weight of a portion of the tank contents adjacent to the shell for unanchored tanks, or by anchorage of the tank shell. For unanchored tanks, the portion of the contents that may be used to resist overturning is dependent on the width of the bottom annulus. The annulus may be a separate ring or an extension of the bottom plate if the required thickness does not exceed the bottom thickness. The weight of the annulus that lifts off the foundation shall be determined by the formula

*When tanks are located in an active fault zone capable of generating a maximum credible earthquake of Richter magnitude 7.0 or greater, consideration should be given to developing a response spectra for the site.

Copyright by the American Water Works Association
Wed Feb 02 02:15:48 2005

$$w_L = 7.9t_b\sqrt{\sigma_y HG} \leq 1.28HDG \quad \text{(Eq 20)}$$

Where:

w_L = maximum weight of tank contents per foot of shell circumference that may be used to resist the shell overturning moment, in pounds per foot. Eq 20 applies whether or not a thickened annulus is used
t_b = thickness of the bottom annulus, in inches
σ_y = minimum specified yield strength of bottom annulus, in pounds per square inch
H = maximum depth of water, in feet
G = specific gravity (1.0 for water)
D = tank diameter, in feet

12.3.3.2 The bottom annulus may be thicker than the bottom shell course, but the thickness t_b, used to calculate seismic stability, shall not exceed the thickness of the bottom shell course. When the bottom annulus is thicker than the remainder of the bottom, the total width of the bottom annulus shall be equal to or greater than that determined by the formula

$$L \geq 0.216t_b\sqrt{\frac{\sigma_y}{HG}} \leq 0.035D, \text{ in feet} \quad \text{(Eq 21)}$$

Where:

L = total width of the bottom annulus measured from the inside of the shell, in feet, but is not to exceed $0.035D$

NOTE: If L exceeds $0.035D$, the tank must be anchored.

The other symbols are previously defined in this section, under Eq 20.

12.3.4 *Shell compression in unanchored tanks.*

12.3.4.1 The maximum longitudinal shell compression stress at the bottom of the shell when there is no uplift shall be determined by the formula

$$\sigma_c = \left(w_t + \frac{1.273M}{D^2}\right)\frac{1}{12t_s}(\text{psi}) \quad \text{(Eq 22)}$$

These terms are defined in this section, under Eq 16, 17, and 25.

NOTE: There is no uplift when the quantity resulting from Eq 23 is equal to or less than 0.785.

$$\frac{M}{D^2(w_t + w_L)} \leq 0.785 \quad \text{(Eq 23)}$$

12.3.4.2 The maximum longitudinal shell compression stress at the bottom of the shell when there is uplift shall be determined by the formula

Copyright by the American Water Works Association
Wed Feb 02 02:15:48 2005

$$\sigma_c = \left[\frac{w_t + w_L}{0.6070 - 0.18667\left(\frac{M}{D^2(w_t + w_L)}\right)^{2.3}} - w_L \right] \frac{1}{12t_s} \text{ (psi)} \qquad \text{(Eq 24)}$$

NOTE: There is limited uplift when Eq 25 yields a quantity greater than 0.785 but equal to or less than 1.54.

$$0.785 < \frac{M}{D^2(w_t + w_L)} \leq 1.54 \qquad \text{(Eq 25)}$$

When Eq 25 yields a quantity greater than 1.54, the bottom annulus must be thickened (maximum thickness = t_s) or the tank must be anchored. In thickening the bottom annulus, the intent is not to force a thickening of the lowest shell course, thereby inducing an abrupt thickness change in the shell, but rather to impose a limit on the annulus ring thickness based on the shell design.

In Eq 22, 23, 24, and 25:

σ_c = maximum longitudinal shell compression stress, in pounds per square inch

t_s = thickness of bottom shell course, in inches

w_t = weight of the tank shell and portion of the roof reacting on the tank shell, in pounds per foot of shell circumference determined by the formula

$$w_t = \frac{W_s}{\pi D} + w_{rs} \qquad \text{(Eq 26)}$$

w_{rs} = roof load acting on shell in pounds per foot of shell circumference. Only permanent roof loads shall be included. Roof live load shall not be included.

The other symbols are previously defined in this section.

NOTE: The maximum longitudinal shell compression stress σ_c must be less than the earthquake allowable stress σ_e, which is determined in compliance with Sec. 12.3.7.4.

12.3.5 *Shell compression and anchor loads in anchored tanks.* When an anchored tank is required, the maximum longitudinal compression stress at the bottom of the shell shall be determined by Eq 22. The anchor tensile load is determined as follows:

$$T_B = S_L\left[\frac{1.273M}{D^2} - w_t\right] \qquad \text{(Eq 27)}$$

Where:

T_B = anchor tension, in pounds

S_L = anchor spacing, in feet

The other symbols have been previously defined in this section.

Copyright by the American Water Works Association
Wed Feb 02 02:15:48 2005

12.3.6 *Hydrodynamic seismic hoop tensile stresses.* Hydrodynamic seismic hoop tensile stresses shall be determined by the following formulas.

1. When vertical acceleration is not specified,

$$\sigma_s = (N_i + N_c)/t \qquad \text{(Eq 28)}$$

for $D/H \geq 1.333$:

$$N_i = 11.35\left[\frac{ZI}{R_w}\right]GDH\left[\frac{Y}{H} - 0.5\left(\frac{Y}{H}\right)^2\right]\tanh\left(0.866\frac{D}{H}\right) \qquad \text{(Eq 29)}$$

For $D/H < 1.333$ and $Y < 0.75D$:

$$N_i = 6.98\left[\frac{ZI}{R_w}\right]GD^2\left[\frac{Y}{0.75D} - 0.5\left(\frac{Y}{0.75D}\right)^2\right] \qquad \text{(Eq 30)}$$

For $D/H < 1.333$ and $Y \geq 0.75D$:

$$N_i = 3.50\left[\frac{ZI}{R_w}\right]GD^2 \qquad \text{(Eq 31)}$$

For all values of D/H:

$$N_c = \frac{17.55\left[\frac{ZI}{R_w}\right]C_1SGD^2\cosh\left[\frac{3.68(H-Y)}{D}\right]}{\cosh\left[\frac{3.68H}{D}\right]} \qquad \text{(Eq 32)}$$

2. When vertical acceleration is specified,

$$\sigma_s = \frac{\sqrt{N_i^2 + N_c^2 + (N_h a_v)^2}}{t} \qquad \text{(Eq 33)}$$

Where:

σ_s = hydrodynamic hoop stress, in pounds per square inch
N_i = impulsive hoop force, in pounds per inch* of shell height, at the design point
N_c = convective hoop force, in pounds per inch* of shell height, at the design point

*Derived from reference 1 in Sec. 12.8. When a response spectra is specified that does not extend out to the period of the sloshing, it is acceptable to calculate spectral velocity by the formula in Sec. 12.3.2.3.

Copyright by the American Water Works Association
Wed Feb 02 02:15:49 2005

N_h = hydrostatic force, in pounds per inch of shell height, at the design point

$$= 2.6GYD \qquad \text{(Eq 33a)}$$

a_v = vertical acceleration (decimal). This value shall be three fourths of the impulsive acceleration, unless otherwise specified

t = thickness of the shell ring under consideration, in inches (millimetres)

Y = distance from fluid surface, in feet (positive down) to the bottom of the ring or design point under consideration

The other symbols have been previously defined in this section.

The hydrodynamic hoop tensile stresses shall be added to the hydrostatic stress in determining the total stress.

12.3.7 *Additional considerations.*

12.3.7.1 If vertical acceleration is specified, the purchaser shall indicate the magnitude of acceleration, if different from that given in Sec. 12.3.6.

12.3.7.2 The purchaser shall specify the amount of freeboard to be provided for the sloshing wave. Freeboard is defined as the distance from the top capacity level to the lowest level of the roof framing. If the purchaser chooses to specify no additional freeboard, some loss of contents and roof damage may occur if the tank is completely full during an earthquake. The sloshing wave height may be calculated by the formula

$$d = 7.53D\left[\frac{ZIC_1S}{R_w}\right] \qquad \text{(Eq 34)}$$

Where:

d = wave height above top capacity level, in feet

The other symbols have been previously defined in this section.

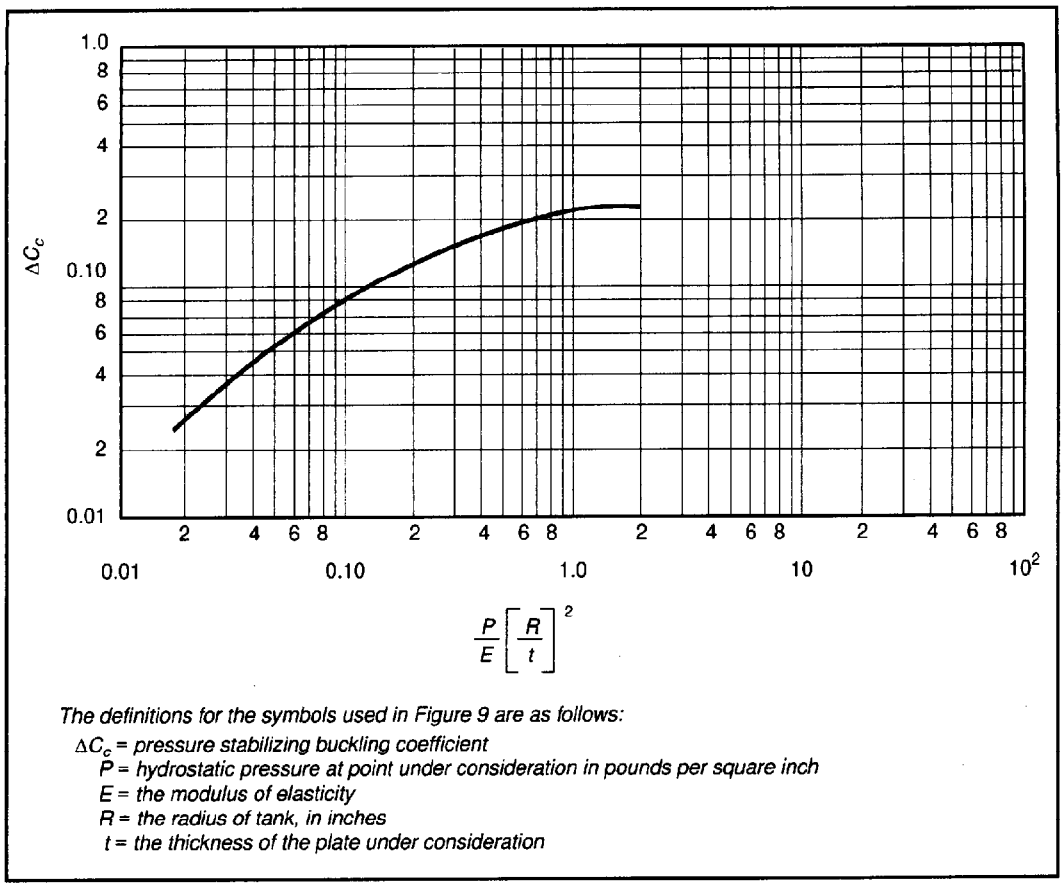
12.3.7.3 Seismic design of roof framing and columns shall be made if specified by the purchaser. The purchaser shall specify the amount of live loads and vertical acceleration to be used in seismic design. Columns shall be designed for lateral water loads and acceleration as specified by the purchaser. Seismic beam-column design shall be based on the primary member allowable stresses, set forth in AISC (ASD), increased by one third for seismic loading.

12.3.7.4 Allowable shell plate stresses in tension for the material used shall be based on the stress allowable in Sec. 3. A one-third increase in basic allowable shell plate stress is permitted for seismic loadings.

In compression, the effect of internal liquid pressure on increasing buckling allowable stresses in Figure 9 shall be included with a safety factor of 2.0 in the design of unanchored tanks subjected to seismic loading (refer to reference 5 in Sec. 12.8).* The earthquake allowable stress is determined by the following formulas:

*The concept of increased stability due to internal pressure is supported by field observations and model tests. The increase in allowable stress due to pressure is permitted for a "once in a lifetime stress." Conservative non-pressure allowables are used for operating loads since consideration must be made for longevity, maintenance, settlement, tolerances, discontinuities, and so forth.

Copyright by the American Water Works Association
Wed Feb 02 02:15:49 2005



The definitions for the symbols used in Figure 9 are as follows:

ΔC_c = *pressure stabilizing buckling coefficient*
P = *hydrostatic pressure at point under consideration in pounds per square inch*
E = *the modulus of elasticity*
R = *the radius of tank, in inches*
t = *the thickness of the plate under consideration*

Figure 9 Increase in axial-compressive buckling-stress coefficient of cylinders due to internal pressure (for use with unanchored tanks)

For unanchored tanks:

$$\sigma_e = 1.333\left(f_s + \frac{\Delta\sigma_{cr}}{2}\right) \quad \text{(Eq 35)}$$

Where:

σ_e = earthquake allowable stress, in pounds per square inch
f_s = allowable compressive stress, in pounds per square inch, determined by the formula in Sec. 3.4.2
$\Delta\sigma_{cr}$ = critical buckling stress increase due to pressure, in pounds per square inch, determined by the formula

$$\Delta\pi_{cr} = \frac{\Delta C_c E t}{R} \quad \text{(Eq 36)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:15:49 2005

Where:

ΔC_c = pressure stabilizing buckling coefficient (see Figure 9)
E = modulus of elasticity, 29,000,000 psi
t = thickness of the plate under consideration, in inches
R = radius of the tank, in inches

For anchored tanks:

$$\sigma_e = 1.333 f_s \qquad \text{(Eq 37)}$$

12.3.7.5 Tank sliding. Ground-supported tanks full of product have not been found to slide off their foundation. When a sliding check is specified by the purchaser, a coefficient of friction equal to tan 30° can be assumed. The actual lateral base shear, V_{act}, shall be less than the allowable lateral base shear, V_{allow}.

$$V_{allow} = \tan 30°(W_s + W_r + W_1 + W_2)(1.0 - 0.4a_v) \qquad \text{(Eq 38)}$$

Where:

V_{allow} = allowable lateral shear in pounds
$V_{act} < V_{allow}$

NOTE: See Sec. 12.3.1 (Eq 15) for determination of V_{act}.

$$\frac{P}{E}[R/t]^2$$

Where:

ΔC_c = pressure stabilizing buckling coefficient (see Figure 9)
P = hydrostatic pressure at point under consideration, in pounds per square inch
E = modulus of elasticity
t = thickness of the plate under consideration, in inches
R = radius of the tank, in inches

NOTE: When $\frac{P}{E}[R/t]^2$ exceeds 2.0, inelastic buckling occurs. Design is beyond the scope of this standard.

Sec. 12.4 Local Seismic Data

When a spectral-response curve is provided for a given location, it may be used in place of acceleration and spectral velocity values in this section. A 2-percent damped curve is recommended for determining acceleration of a structure, and a 0.5-percent damped curve is recommended for determining acceleration of the sloshing liquid. The amplified acceleration shall be determined for the cantilever beam period of the shell and effective portion of the contained liquid.

Copyright by the American Water Works Association
Wed Feb 02 02:15:49 2005

12.4.1 *Scaling down site response spectra.* Scaling down a site-specific response spectra is appropriate for ductile modes of failure, such as hoop tension. Nonductile modes of failure, such as elephant foot buckle at the base of ground-supported tanks may also be scaled down. Buckling loads that may result in total collapse of the structure shall not be scaled down. Scaling down will depend on the return period of the earthquake used to generate the response spectra. A reduction factor, R_F, of 2.5 shall be used for ground motion with a mean recurrence interval of 10,000 years. Where information is not available to accurately determine a recurrence level, the maximum credible ground motion based on seismology, geology, and seismic and geologic history of the site may be used to determine a site-specific response spectra. For lower recurrence spectra, the spectra may be scaled down, but in no case shall the final design acceleration be less than that calculated using values from Tables 3 through 6 and Eq 15 and 16.

Sec. 12.5 Piping Connections

A minimum 2 in. of flexibility in the vertical and tangential directions in either direction from the pipe centerline shall be provided for all piping attached to the shell.

12.5.1 *Bottom connection for unanchored flat-bottom tanks.* The bottom connection on an unanchored flat-bottom tank shall be located inside the shell a sufficient distance to minimize damage by uplift. At a minimum, the distance measured to the edge of the connection reinforcement shall be the width of the calculated unanchored bottom hold-down plus 12 in. (305 mm), as shown in Figure 10.

Sec. 12.6 Foundation Design

A one-third increase in allowable stress shall be permitted in foundation design.

12.6.1 *Anchored flat-bottom tank.* Ringwalls and footings for anchored flat-bottom tanks shall be proportioned to resist maximum anchor-bolt uplift and overturning bearing pressure. Water load directly over the ringwall and footing may be used to resist the maximum anchor bolt uplift, provided the ringwall and footing are designed to carry the eccentric loading. Water shall not be used to reduce the anchor bolt load.

12.6.2 *Unanchored flat-bottom tank.* Calculated toe pressure to satisfy equilibrium on unanchored flat-bottom tanks produces impractical ringwall dimensions.

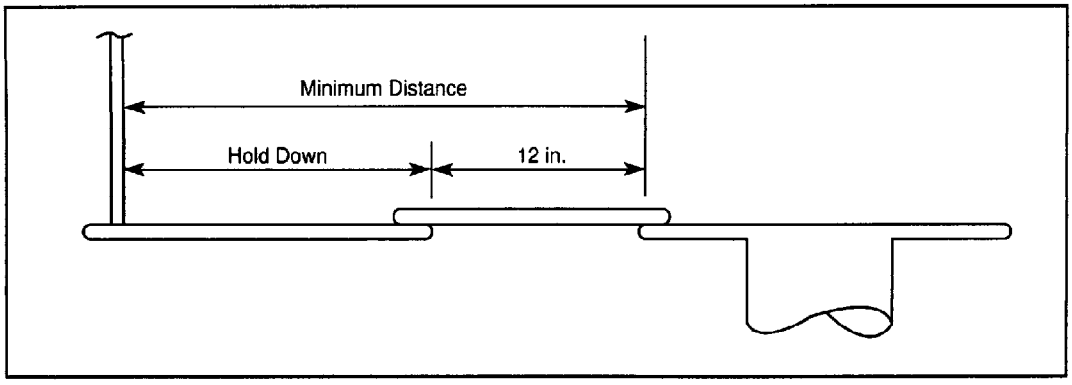


Figure 10 Bottom piping connection of an unanchored flat-bottom tank (12 in. = 304.8 mm)

Copyright by the American Water Works Association
Wed Feb 02 02:15:50 2005

Some yielding of soil (settlement) may occur under the shell, requiring releveling of the tank after an earthquake. The foundations under flat-bottom tanks, even tanks resting directly on earth foundations, have fared well under seismic loadings. Therefore, the seismic loading does not alter the foundation design criteria or provide justifications for increased foundations for ring-bearing plates.* Design-bearing pressure should be determined using the same method as for an anchored tank condition. This assumption does not permit a larger R_w factor from Table 4. R_w shall be 3.5.

12.6.3 *Unanchored tank vaults.* If a vault or ringwall penetration exists, that portion under the shell shall be designed to carry the calculated shell load on its unsupported spans.

Sec. 12.7 Tabulation Forms for Seismic Data and Example

Figure 11A presents a blank tabulation form for seismic data to be completed by the purchaser. An example tabulation form and corresponding design calculations are presented below.

Example:

Determining the adequacy of using a 0.1495-in. (3.8-mm)-thick bottom shell course in a 21-ft (6.4-m) diameter by 24-ft (7.3-m) shell-height tank. The tank is located in seismic zone 4, and there is no soil information available. Assume the tank is to be anchored.

H_t = 24 ft (NOTE: In this example there is no freeboard, and the maximum depth of water H is the same as the shell H_t.)
D = 21 ft
G = 1.0
t_s = 0.1495 in. (bottom shell course thickness)
X_s = $H/2$, or 24/2 = 12 ft
W_s = 6,800 lb
W_r = 1,500 lb
w_{rs} = 15 lb/ft
D/H = 21/24 = 0.875

See completed tabulation form (Figure 11B) for seismic data for Z, R_w, I, and S, with values of 0.4, 4.5, 1.25, and 1.5, respectively.

Solution:

1. Overturning moment (see Sec. 12.3.1, Eq 16)

$$M = 18\frac{ZI}{R_w}[0.14(W_sX_s + W_rH_t + W_1X_1) + SW_2X_2C_1]$$

The unknown quantities for this equation are found as follows:

a. $W_1 = 0.82W_T$ (see Sec. 12.3.2.1 and Figure 7)

*A "ring-bearing plate" is a plate located under the shell to spread the unanchored shell compressive stress.

Figure 11B Completed tabulation form for design example

Copyright by the American Water Works Association
Wed Feb 02 02:15:50 2005

In this formula

$$W_T = \left(\frac{\pi D^2}{4}\right) H 62.4 \text{ (see Sec. 12.3.2.1, Eq 17)}$$

Substituting the known quantities

$$W_T = [(\pi \times 21^2)/4] \times 24 \times 62.4$$
$$= 518{,}710 \text{ lb}$$

$$W_1 = 0.82 \times 518{,}710$$
$$= 425{,}342 \text{ lb}$$

b. $W_2 = 0.20 W_T$ (see Sec. 12.3.2.1 and Figure 7)

Substituting the known quantities

$$W_2 = 0.20 \times 518{,}710$$
$$= 103{,}742 \text{ lb}$$

c. $X_1 = 0.42H$ (see Sec. 12.3.2.2 and Figure 8)

Substituting the known quantities

$$X_1 = 0.42 \times 24$$
$$= 10 \text{ ft}$$

d. $X_2 = 0.77H$ (see Sec. 12.3.2.2 and Figure 8)

Substituting the known quantities

$$X_2 = 0.77 \times 24$$
$$= 18.5 \text{ ft}$$

e. $C_1 = 1/(6T_w)$ when $T_w < 4.5$ seconds

or

$C_1 = 0.75/T_w^2$ when $T_w \geq 4.5$ seconds (see Sec. 12.3.1, Eq 16a and 16b)

In these formulas,

$T_w = K_p D^{1/2}$ (see Sec. 12.3.1, Eq 16c, and Figure 6)

Substituting the known quantities

$$T_w = 0.57 \times 21^{1/2}$$
$$= 2.61$$

the formula $C_1 = 1/(6T_w)$ governs, and substituting the known quantities,

$$C_1 = 1/(6 \times 2.61)$$
$$= 0.064$$

Copyright by the American Water Works Association
Wed Feb 02 02:15:50 2005

Substituting the known quantities in the overturning moment formula

$$M = \frac{18(0.4)(1.25)}{4.5}[0.14(6{,}800 \times 12 + 1{,}500 \times 24 + 425{,}342 \times 10)$$

$$+ 1.5 \times 103{,}742 \times 18.5 \times 0.064] = 1{,}592{,}377 \text{ ft} \cdot \text{lb}$$

2. Shell compressive stress for anchored tank

$$\sigma_c = \left(w_t + \frac{1.273M}{D^2}\right)\frac{1}{12t_s} \text{ (see Sec. 12.3.5, Eq 22)}$$

The unknown quantity for this equation is found as follows:

$w_t = W_s/\pi D + w_{rs}$ (see Sec. 12.3.4.2, Eq 26)

Substituting the known quantities

$w_t = 6{,}800/\pi(21) + 15$

$= 118$ lb/ft

Substituting the known quantities in the shell compressive stress formula

$$\sigma_c = \left(118 + \frac{1.273 \times 1{,}592{,}377}{21^2}\right) \times \frac{1}{12(0.1495)}$$

$= 2{,}628$ psi

3. Earthquake allowable compressive stress

$$\sigma_e = 1.333 f_s \text{ (see Sec. 12.3.7.4, Eq 37)}$$

In this equation, try shell thickness $t = 0.1495$ in. The unknown quantity for Eq 37 is found as follows:

a. $$f_s = 15{,}000\left(\frac{2}{3}\right)\left(100\frac{t}{R}\right)\left[2 - \left(\frac{2}{3}\left(100\frac{t}{R}\right)\right)\right] \text{ (see Sec. 3.4.2)}$$

Substituting the known quantities

$$f_s = 15{,}000\left(\frac{2}{3}\right)\left(100\frac{0.1495}{10.5 \times 12}\right)\left[2 - \left(\frac{2}{3}\left(100\frac{0.1495}{10.5 \times 12}\right)\right)\right]$$

$= 2{,}279$ psi

Substituting the known values in the earthquake compressive stress formula (Eq 37)

$\sigma_e = 1.333(2{,}279)$

$\sigma_e = 3{,}038$ psi

Copyright by the American Water Works Association
Wed Feb 02 02:15:50 2005

STD·AWWA D103-ENGL 1997 ■ 0783350 0505518 507 ■

Conclusion:

Since the earthquake compressive stress of 3,038 psi is greater than the shell compressive stress of 2,628 psi, the shell thickness of 0.1495 in. is acceptable for an anchored tank.

SECTION 13: STRUCTURALLY SUPPORTED ALUMINUM DOME ROOFS

Sec. 13.1 General

This section establishes minimum criteria for the design, fabrication, and erection of structurally supported aluminum dome roofs. Aluminum dome roofs can be used on any size tank erected in accordance with this standard. When this section is required by the purchaser, it supersedes conflicting requirements of other sections. All other requirements of AWWA D103 shall apply.

Sec. 13.2 Definition

The dome shall be a spherical structure conforming to the dimensions of the tank. The dome structure shall be a fully triangulated space truss complete with non-corrugated closure panels. The dome shall be clear span and designed to be self-supporting from the tank structure. The dome surface paneling shall be designed as a watertight system under all design load conditions. All raw edges of the aluminum panels shall be covered, sealed, and firmly clamped in an interlocking manner to prevent slipping or disengagement under all load conditions and temperature changes.

Sec. 13.3 Design Requirements

The tank shall be designed to support the aluminum dome roof. The roof manufacturer shall supply the tank manufacturer with the magnitude and direction of all the forces acting on the tank due to the roof loads and details of the roof-to-shell attachment. The tank shall be designed to support given roof loads and attachment details. Dissimilar metals shall be isolated to prevent galvanic corrosion. For new

Copyright by the American Water Works Association
Wed Feb 02 02:15:51 2005

tanks, the tank manufacturer shall certify that the tank has been designed to support the aluminum dome roof. For existing tanks, the purchaser or purchaser's agent shall make such a verification. The aluminum dome roof shall be supported from the rim of the tank with primary horizontal thrust contained by an integral roof tension ring. Provisions shall be made in the design of the connection between the roof and tank rim to allow for thermal expansion. A minimum range of –40°F to +140°F (–40°C to +60°C) shall be used for design unless a greater range is specified by the purchaser.

Sec. 13.4 Materials

13.4.1 *General.* All materials furnished to meet the provisions of this section shall be new and shall comply with all the requirements of this section. All aluminum alloys, properties, and tolerances shall be as defined by the Aluminum Association's *Aluminum Standards and Data*. Unless specified by the purchaser, the aluminum dome roof materials shall have a mill finish.

13.4.2 *Structural frame.* All structural frame members shall be made from AA6061-T6 or a recognized alloy with properties established by the Aluminum Association.

13.4.3 *Roof panels.* Roof panels shall be fabricated from AA3000 series or AA5000 series aluminum with a minimum nominal thickness of 0.050 in. (1.27 mm).

13.4.4 *Bolts and fasteners.* All fasteners shall be AA7075-T73 aluminum or austenitic stainless steel or other materials as accepted by the purchaser. Only stainless steel fasteners shall be used to attach aluminum to steel.

13.4.5 *Sealant and gasket material.* All sealants shall be silicone compounds conforming to Fed. Spec. TT-S-00230 unless another material is required for suitability and compatibility when in contact with potable water. Sealants shall remain flexible over a temperature range of –80°F to +300°F (–62°C to +148°C) without tearing, cracking, or becoming brittle. Elongation, tensile strength, hardness, and adhesion shall not change significantly with aging or from exposure to ozone, ultraviolet light, or vapors from the water stored in the tank.

All preformed gasket material shall be made of silicone meeting Fed. Spec. ZZ-R-765D, class 2, grade 50, or a purchaser-approved equal, unless another material is required for compatibility with potable water stored in the tank.

13.4.6 *Skylight panels.* Skylight panels, if specified by the purchaser, shall be clear acrylic or polycarbonate with a minimum nominal thickness of 0.25 in. (6.4 mm).

Sec. 13.5 Allowable Stresses

13.5.1 *Aluminum structural members.* Aluminum structural members and their connections shall be designed in accordance with the Aluminum Association's *Specifications for Aluminum Structures*, except as modified by this section.

For members subjected to axial forces and bending moments due to load eccentricity or lateral loads, the combined member stresses shall be determined by adding the stress component due to axial load to the stress components that result from bending in both the major and minor axes.

Allowable shell buckling loads shall be determined in accordance with the following formula:

$$w = \frac{2{,}258 \times 10^6 (I_x A)^{1/2}}{(SF)R^2 L} \qquad \text{(Eq 39)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:15:51 2005

Where:

w = allowable load (pressure), in pounds per square foot
I_x = moment of inertia of strut about the strong axis, in inches^4
A = cross-sectional area of strut, in square inches
R = spherical radius of dome, in inches
L = average member length, in inches
SF = safety factor (1.65)

13.5.2 *Aluminum panels.* Aluminum panels shall be designed to support the loads specified in Sec. 13.6 without exceeding the allowable stresses specified in the Aluminum Association's *Specification for Aluminum Structures.* Panel attachment fasteners shall not penetrate both the panel and flange of the structural member.

13.5.3 *Bolts and fasteners.* For fasteners not listed in Table 7, the allowable stress in bolts and fasteners shall be in accordance with the Aluminum Association's *Specifications for Aluminum Structures* and the AISI *Stainless Steel Cold Formed Structural Design Manual for Aluminum and Stainless Steel Bolts,* respectively.

Hole diameters used for fasteners shall not exceed 1/16 in. (1.6 mm) plus the diameter of the fastener used.

Sec. 13.6 Design

13.6.1 *Detail drawings and calculations.* Detail drawings and calculations certified by a professional engineer experienced in the design of these structures shall be provided when specified by the purchaser (refer to Sec. 1.4).

13.6.2 *Principles of design.* The roof framing system shall be designed as a moment-resisting, three-dimensional space frame or truss with a membrane covering (roof panels) providing loads along the length of the individual members. The design shall consider the increased compression and minor axis bending induced in the framing members as a result of the tension in the roof panels. The design loads shall not exceed the allowable buckling loads set forth in Sec. 13.5.1. The actual stresses in

Table 7 Bolts and fasteners

Material	Allowable Tensile Stress*†		Allowable Shear Stress*†‡	
	psi	(*MPa*)	*psi*	(*MPa*)
Austenitic Stainless Steel (§)	30,000	(206.9)	18,000	(124.1)
Austenitic Stainless Steel (**)	42,000	(289.7)	25,000	(172.4)
AA2024-T4 Aluminum	26,000	(179.2)	16,000	(110.3)
AA7075-T73 Aluminum	28,000	(193.0)	17,000	(117.2)

NOTES:

*The root of thread area shall be used for calculating the strength of threaded parts.

†If the thread area is completely out of the shear area the cross-sectional area of shank may be used to determine the allowable shear load.

‡For wind and seismic loads, these values may be increased by one third.

§For stainless steel bolts with a minimum tensile strength of 90,000 psi (620.5 MPa).

**For stainless steel bolts with a minimum tensile strength of 125,000 psi (861.8 MPa).

Copyright by the American Water Works Association
Wed Feb 02 02:15:51 2005

the framing members and panels under all design load conditions must be equal to or less than the allowable stresses.

The structural analysis shall include the effect of geometric irregularities such as dormer openings and perimeter support members.

13.6.3 *Design loads.* In addition to design loads specified in Sec. 3.2, the following loads shall be considered in the design of the aluminum dome roof.

13.6.3.1 Unbalanced loading. Reduce the live load by 50 percent over one-half the dome.

13.6.3.2 Panel design load. These loads do not act simultaneously with other design loads.

Two 250-lb (113.4-kg) loads concentrated on two separate 1 ft^2 (0.093 m^2) areas of any aluminum panel, or 60 psf (293 kg/m^2) distributed over the total panel area.

13.6.3.3 Wind pressures may also be based on certified wind tunnel test results.

13.6.3.4 The minimum wind load shall be the load resulting from a wind velocity of 100 mph (45 m/second) unless a different wind velocity is specified by the purchaser. Wind loading shall be determined in agreement with Sec. 3.2.4.

13.6.3.5 If the tank is designed for seismic loads, the roof shall be designed for a horizontal seismic force determined by using the procedures of Sec. 12.

13.6.3.6 The following load combinations shall be considered:

1. Dead load
2. Dead load + Uniform live load
3. Dead load + Unbalanced live load
4. Dead load + Wind load
5. Dead load + Uniform live load + Wind load
6. Dead load + Unbalanced live load + Wind load
7. Dead load + Seismic load

Sec. 13.7 Roof Attachment Details

The structure supports provided to support the aluminum dome roof shall be bolted or welded to the tank. The number of attachment points shall be determined by the roof manufacturer in consultation with the tank manufacturer to preclude overloading the tank shell. The attachment detail shall be suitable to transfer all roof loads to the tank shell, keeping local stresses within allowable limits.

13.7.1 *Roof supports.* The roof attachment points may incorporate a slide bearing with low-friction bearing pads to minimize the horizontal radial forces transferred to the tank. Alternatively, the roof may be attached directly to the tank and the top of the tank analyzed and designed to sustain the horizontal thrust transferred from the roof, including the thrust from differential thermal expansion and contraction.

13.7.2 *Separation of carbon steel and aluminum.* Aluminum shall be isolated from the carbon steel by an austenitic stainless steel spacer or an elastomeric isolator bearing pad, unless other methods are specified by the purchaser.

Sec. 13.8 Physical Characteristics

The maximum dome spherical radius shall be 1.4 times the diameter of the tank. The minimum dome spherical radius shall be 0.7 times the tank diameter unless otherwise specified by the purchaser.

13.8.1 *Roof accessories.* Roof accessories shall conform to the provisions of Sec. 5, as applicable.

Copyright by the American Water Works Association
Wed Feb 02 02:15:51 2005

STD.AWWA D103-ENGL 1997 ■ 0783350 0505522 T38 ■

13.8.2 *Skylights.* Skylights, if specified by the purchaser, shall be furnished with a 4 in. (102 mm) or higher curb and shall be designed for the live and wind loads specified for the roof. The purchaser shall specify the total skylight area to be provided.

Sec. 13.9 Testing and Sealing

13.9.1 *Leak testing.* After completion, the roof seams shall be leak tested by spraying the outside with water from a hose with a minimum 50 psig (345 kPa) static head pressure at the nozzle. Potable water shall be used. The water must not be sprayed directly on any roof vents. Any water on the inside of the roof shall be evidence of leakage.

Sec. 13.10 Fabrication and Erection

The manufacturer of the roof and constructor shall perform the work described in this standard with qualified supervision that is skilled and experienced in the fabrication and erection of aluminum structures. The dome shall be erected in accordance with the manufacturer's instructions.

13.10.1 *Fabrication.* All roof parts shall be prefabricated for field assembly. Fabrication procedures shall be in accordance with Sec. 6 of the Aluminum Association's *Specifications for Aluminum Structures.*

13.10.2 *Welding.* The fabrication and design of welded aluminum parts shall be in accordance with Sec. 7 of the Aluminum Association's *Specifications for Aluminum Structures,* and ANSI/AWS D1.2, Structural Welding Code—Aluminum. All aluminum structural welds and components joined by welding shall be visually inspected and tested by the dye-penetrant method of examination in accordance with ANSI/AWS D1.2, Sec. 6.7.5. All structural welding of aluminum shall be performed prior to field erecting of the dome. A full set of satisfactory examination and qualification records shall be delivered to the purchaser if requested, prior to field erection.

13.10.3 *Shipping and handling.* Materials shall be handled, shipped, and stored in a manner that will not damage the surface of aluminum or the surface coating of steel.

13.10.4 *Workmanship.* The roof shall be installed so as to minimize internal stresses on the structure when bolted together, and to the supports. The basic component parts of the structure shall be erected with precise fit and alignment. Field cutting, trimming, relocating of holes, or the application of force to the parts to achieve fitup is not acceptable.

13.10.5 *Maintenance and inspection.* The manufacturer of the roof shall provide a maintenance and inspection manual for those items that may require maintenance or periodic inspection.

Sec. 13.11 Coatings

Aluminum dome roofs shall have a mill finish. If a color other than mill-finish aluminum is desired for aesthetic reasons, the exterior of the dome may be specified to have a factory-applied, baked-on finish.

Exterior coatings may be thermosetting, acrylic, silicone polyester, or fluorocarbon.

NOTE: No coatings are to be applied to the interior surfaces of the dome, either in the manufacturer's shop or in the field.

The coating shall meet the requirements of AAMA 605.1 for high-performance organic coating on architectural extrusions and panels.

The coating shall also meet the weathering requirements specified in ASTM D2244.

APPENDIX A

Metric (SI) Equivalents

This appendix is for information only and is not a part of AWWA D103.

Metric units used are those of the International System of Units (SI), which is officially recognized by all industrial nations. This document may be supplemented by ASTM* E380, Metric Practice Guide.

Table A.1 lists selected SI conversions for the convenience of users of this standard.

Table A.1 Metric (SI) conversion factors

Property	To Convert US Customary Units From	To Metric (SI) Units	Multiply by*
Area	square inch (in.^{2})	millimetre squared (mm^2)	6.451 600*E + 02
		metre squared (m^2)	6.451 600*E – 04
	square foot (ft^2)	metre squared (m^2)	9.290 304*E – 02
Force	pound–force (lbf)	newton (N)	4.448 222 E + 00
	kip (1,000 lbf)	newton (N)	4.448 222 E + 03
Force/Area	pound-force/foot^2 (lbf/ft^2)	newton/metre^2 (N/m^2)	4.788 026 E + 01
Impact strength	foot-pound force (ft•lbf)	joule (J)	1.355 818 E + 00

AWWA D110a-96

Addendum to ANSI/AWWA D110-95

Standard for Wire- and Strand-Wound Circular-Prestressed Concrete

(Approved by the AWWA Board of Directors on June 23, 1996.)

P. 32, Sec. 4.3.1(4), revise as follows:

"(4) The tank's natural period T_I may be determined by a rational analysis that considers the weight of the tank wall and roof and effective weight W_I of the tank contents. The tank's natural period T_I shall be limited to 0.3 s or less for Sec. 4.2.1, Figure 4A tanks. For Sec. 4.2.1, Figure 4B and 4C tanks, T_I shall be determined from Eq 4-8. Refer to Sec. 4.1.2 for definition of symbols.

$$T_I = \sqrt{\frac{4\pi (W_S + W_R + W_I)}{g\, r\, k}} \qquad \text{(Eq 4-8)}$$

P. 35, Sec. 4.3.2, replace with the following:

"4.3.2 *Application of site response spectrum.* Where site-specific response spectra are used, the accelerations of the two masses shall replace the seismic coefficient as follows:

A_I replaces ZIC_I (in g) in Eq 4-1, 4-4, and 4-24, providing the following alternative equations:

$$V_I = \frac{A_I}{R_I}(W_S + W_R + W_I) \qquad \text{(Eq 4-1A)}$$

$$M_I = \frac{A_I}{R_I}(W_S X_S + W_R H_t + W_I X_I) \qquad \text{(Eq 4-4A)}$$

$$N_I = \frac{A_I}{\pi R_I}\left(\frac{W_S}{2} + W_R + W_I\right) \qquad \text{(Eq 4-24A)}$$

Similarly, $\sqrt{3.375}\ \frac{D_c}{r}\ \tanh\ (\sqrt{3.375}\ H/r)$ replaces ZIC_c (in g) in Eq 4-2, 4-5, 4-25, 4-28, and 4-29.

Refer to Sec. 4.1.2 for definition of symbols.

Copyright by the American Water Works Association
Wed Feb 02 02:16:32 2005

For tanks with a Sec. 4.2.1, Figure 4A base joint, the natural period T_I shall be taken as the period in the range of 0.0 s to 0.3 s that gives the largest base shear, unless a more precise determination of period is performed.

The zone coefficients Z represent, within the accuracy that can be expected of such a system, the peak ground accelerations that have a 10 percent chance of being exceeded in 50 years. When multiplied by an importance factor I of 1.25, the probability of being exceeded drops to 5 percent. Similar probabilities should be used for site-specific response spectra. The results obtained by using site-specific response spectra shall not be less than those determined by the zone-based Eq 4-1, 4-2, 4-4, 4-5, 4-24, 4-28, and 4-29."

P. 37, Sec. 4.5.3, revise Eq 4-24, with the following:

"4.5.3 *Equivalent axisymmetric hoop loads.* Hydrodynamic seismic membrane hoop tensile stresses in the circumferential direction, radial shear, and vertical bending moments shall be determined by applying the equivalent axisymmetric hoop loads due to the response of the mass of the tank roof and shell (wall) combined with the equivalent axisymmetric hoop load due to the response of the mass of the tank contents given by Eq 4-24, 4-25, 4-26, and 4-27. The maximum radial force, summed over the full height of the tank wall (see the last two paragraphs in this section for the vertical distribution of these forces) for each component, may be obtained by dividing the following equivalent axisymmetrical hoop loads by the radius:

$$N_I = \frac{ZIC_I}{\pi R_I}\left(\frac{W_S}{2} + W_R + W_I\right) \qquad \text{(Eq 4-24)}$$

NOTE: The roof weight W_R need not be included in Eq 24 for tanks with shear connections between the wall and roof that only transfer forces tangential to the wall.

$$N_C = \frac{ZIC_C}{R_C}(W_C)\left(\frac{8}{9\pi}\right) \qquad \text{(Eq 4-25)}$$

$$N_V = \frac{\ddot{u}_V \gamma H^2 R}{2} \qquad \text{(Eq 4-26)}$$

$$N_T = \sqrt{N_I^2 + N_C^2 + N_V^2} \qquad \text{(Eq 4-27)}$$

The vertical distribution of the impulsive hoop loads, resulting from the response of the tank contents, shall be Housner's (see appendix A, reference 5) impulsive pressure distribution, or a trapezoid that approximates this distribution, increasing linearly from top to bottom. The centroid of the impulsive hoop load distribution shall be located at a height from the bottom of the tank shell equal to the centroid X_I of the impulsive portion W_I of the tank contents. The impulsive hoop loads shall not be distributed over a height greater than the depth of the water H.

The vertical distribution of the convective hoop loads, due to the response of the tank contents, shall be Housner's convective pressure distribution, or a trapezoid that approximates this distribution, decreasing linearly from top to bottom. The centroid of the convective hoop load distribution shall be located at a height from the bottom of the tank shell equal to the centroid X_C of the convective portion W_C of the tank contents. The convective hoop loads shall not be distributed over a height greater than the depth of water H.

Copyright by the American Water Works Association
Wed Feb 02 02:16:32 2005

The vertical distribution of the vertical acceleration hoop loads shall be a triangular distribution with the maximum at the bottom. The vertical acceleration loads shall not be distributed over a height greater than the depth of the water *H*.

For purposes of calculating the combined effects on the tank wall and other components, the impulsive, convective, and vertical acceleration loads shall be combined by taking the square root of the sum of the squares of the three components. When determining the required area of circumferential prestressed reinforcement for a given increment of wall height, the square root of the sum of the squares of the three seismic components taken at the mid-height of the increment shall be added to the hydrostatic load at the mid-height of the increment and divided by the allowable stress under seismic loading."

AWWA Standard

This document is an American Water Works Association (AWWA) standard. It is not a specification. AWWA standards describe minimum requirements and do not contain all of the engineering and administrative information normally contained in specifications. The AWWA standards usually contain options that must be evaluated by the user of the standard. Until each optional feature is specified by the user, the product or service is not fully defined. AWWA publication of a standard does not constitute endorsement of any product or product type, nor does AWWA test, certify, or approve any product. The use of AWWA standards is entirely voluntary. AWWA standards are intended to represent a consensus of the water supply industry that the product described will provide satisfactory service. When AWWA revises or withdraws this standard, an official notice of action will be placed on the first page of the classified advertising section of *Journal AWWA*. The action becomes effective on the first day of the month following the month of *Journal AWWA* publication of the official notice.

American National Standard

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. An American National Standard is intended as a guide to aid the manufacturer, the consumer, and the general public. The existence of an American National Standard does not in any respect preclude anyone, whether that person has approved the standard or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standard. American National Standards are subject to periodic review, and users are cautioned to obtain the latest editions. Producers of goods made in conformity with an American National Standard are encouraged to state on their own responsibility in advertising and promotional materials or on tags or labels that the goods are produced in conformity with particular American National Standards.

CAUTION NOTICE: The American National Standards Institute (ANSI) approval date on the front cover of this standard indicates completion of the ANSI approval process. This American National Standard may be revised or withdrawn at any time. ANSI procedures require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of publication. Purchasers of American National Standards may receive current information on all standards by calling or writing the American National Standards Institute, 11 W. 42nd St., New York, NY 10036; (212) 642-4900.

Foreword

This foreword is for information only and is not a part of AWWA D110.

I. Introduction

I.A. *Background.* The New England Water Works Association (NEWWA) established a committee in 1958 to prepare a standard specification for the design and construction of prestressed concrete water-storage tanks. The committee submitted a suggested specification to NEWWA in October 1962 as a guide to those in the water industry who wished to consider the use of these tanks.

American Concrete Institute (ACI) Committee 344 concluded eight years of committee work with a report titled *Design and Construction of Circular Prestressed Concrete Structures,* published in the *ACI Journal* in September 1970. This report referred primarily to wire-wound tanks.

I.B. *History.* In the December 1972 issue of Journal AWWA, the applicability of the ACI report to water containment structures was discussed in four articles. As a result of these articles and continued discussion on the subject, a standards committee was authorized by the American Water Works Association (AWWA) to develop an AWWA standard for circular, prestressed concrete water tanks.

An AWWA Standards committee on circular, prestressed concrete water tanks was appointed and held its first meeting June 19, 1974. During its first two years, the committee studied the various types of prestressed tanks then in service or under construction and determined that most were of the wire-wound type. Therefore, the committee in 1976 was directed to limit its scope to the wire- and strand-wound prestressed tank wall design. The first edition of this standard incorporated the work of ACI Committee 344 and contained additional requirements and recommendations, specifically for potable and process water, and for wastewater containment structures. The new standard, AWWA D110-86, Standard for Wire-Wound Circular Prestressed-Concrete Water Tanks, was approved by the AWWA Board of Directors on June 22, 1986, and had an effective date of June 1, 1987. The standard has been in use since approval by the American National Standards Institute (ANSI) on Mar. 3, 1987.

The first revision of this standard was initiated by the AWWA Standards Committee during 1990 in accordance with AWWA Standards Council policy.

I.C. *Acceptance.* In May 1985, the US Environmental Protection Agency (USEPA) entered into a cooperative agreement with a consortium led by NSF International (NSF) to develop voluntary third-party consensus standards and a certification program for all direct and indirect drinking water additives. Other members of the consortium included the American Water Works Association Research Foundation (AWWARF) and the Conference of State Health and Environmental Managers (COSHEM). The American Water Works Association (AWWA) and the Association of State Drinking Water Administrators (ASDWA) joined later.

In the United States, authority to regulate products for use in, or in contact with, drinking water rests with individual states.* Local agencies may choose to impose requirements more stringent than those required by the state. To evaluate

*Persons in Canada, Mexico, and non–North American countries should contact the appropriate authority having jurisdiction.

Copyright by the American Water Works Association
Wed Feb 02 02:16:35 2005

the health effects of products and drinking water additives from such products, state and local agencies may use various references, including

1. An advisory program formerly administered by USEPA, Office of Drinking Water, discontinued on Apr. 7, 1990.
2. Specific policies of the state or local agency.
3. Two standards developed under the direction of NSF, ANSI*/NSF† 60, Drinking Water Treatment Chemicals—Health Effects, and ANSI/NSF 61, Drinking Water System Components—Health Effects.
4. Other references, including AWWA standards, *Food Chemicals Codex, Water Chemicals Codex*,‡ and other standards considered appropriate by the state or local agency.

Various certification organizations may be involved in certifying products in accordance with ANSI/NSF 61. Individual states or local agencies have authority to accept or accredit certification organizations within their jurisdiction. Accreditation of certification organizations may vary from jurisdiction to jurisdiction.

Appendix A, "Toxicology Review and Evaluation Procedures," to ANSI/NSF 61 does not stipulate a maximum allowable level (MAL) of a contaminant for substances not regulated by a USEPA final maximum contaminant level (MCL). The MALs of an unspecified list of "unregulated contaminants" are based on toxicity testing guidelines (noncarcinogens) and risk characterization methodology (carcinogens). Use of Appendix A procedures may not always be identical, depending on the certifier.

AWWA D110 does not address additives requirements. Thus, users of this standard should consult the appropriate state or local agency having jurisdiction in order to

1. Determine additives requirements, including applicable standards.
2. Determine the status of certifications by all parties offering to certify products for contact with, or treatment of, drinking water.
3. Determine current information on product certification.

II. Special Issues

II.A. *Intent*. This standard reflects a committee consensus of industry practice concerning the design, detailing, and construction of circular, prestressed concrete water tanks of several types, with or without vertical prestressing of the tank core wall. The horizontal prestressed reinforcement of the tank wall is accomplished by the application of helically wound high-tensile-stress wire or strand under controlled tension on the surface of the core wall, protected by shotcrete cover coats.

Recommended criteria and guidelines are presented to assist engineers in the design, construction, and inspection of tanks with shotcrete, cast-in-place concrete, or precast circular concrete core walls, with or without internal steel diaphragms, based on the successful application of these concepts in practice and the detailed experience of committee members. Engineering principles are tied to existing codes where applicable.

---

Wed Feb 02 02:16:35 2005

The intent is also to assist the designer and constructor by sharing information on the unique aspects in analysis and construction that are encountered in these types of structures.

II.B. *Limitations.* Because of the wide range of site-specific environments, foundation conditions, loadings, and construction conditions throughout North America, this standard should not be expected to apply universally nor to produce a cost-effective and completely maintenance-free structure in every situation. In adapting this standard to obtain the structure's expected service life for the actual conditions that are anticipated, the purchaser and the designer of the tank are advised to study carefully all factors affecting the structure during its anticipated service life.

III. Use of This Standard. AWWA has no responsibility for the suitability or compatibility of the provisions of this standard to any intended application by any user. Accordingly, each user of this standard is responsible for determining that the standard's provisions are suitable for and compatible with that user's intended application.

III.A. *Industry Practice and Assumptions.* It is not the purpose of this standard to either define or recommend contractual relationships or to stipulate contractual obligations, both of which are the responsibility of the purchaser. Generally, purchasers may solicit competitive bids for wire- and strand-wound circular prestressed concrete tanks by one of two methods.

Under the first method, a qualified engineer is retained by the purchaser to design the structure and prepare construction drawings, specifications, and other contract documents. Competitive bids are then solicited from constructors and suppliers for construction of the tank. In this standard, these are referred to as *purchaser-furnished designs.*

Under the second method, the purchaser prepares performance specifications that require bidding constructors to prepare detailed project designs and specifications and construct the tank according to the approved design. In this standard, these are referred to as *design-construct projects.*

While the division of information that must be covered in the purchaser's specifications for execution of each project type differs substantially, depending on who is responsible for the tank design, the information that must be supplied by the purchaser to successfully apply this standard is essentially the same.

AWWA D110-95 does not address matters related to site selection and property acquisition. It is assumed that the purchaser will have conducted sufficient background work in the form of water system studies, predesign surveys, subsurface investigations, preliminary design work, etc., to establish the desired tank site, volume, operating water depth, and elevations. Further, it is assumed that the purchaser will have acquired the property, easements, and rights-of-way necessary for construction of site access, the tank structure, and associated water pipelines connecting the tank to the water system and drainage, if required. Specifically, it has been assumed that the purchaser will arrange for or provide the following as necessary or appropriate:

1. The site on which the tank is to be built, with adequate space to permit the constructor to erect the structure using customary methods.

2. A predesign site survey and preparation of a site plan showing existing topography, property lines, approximate tank centerline location, setback, encumbrances, details of special construction features, and extent of final site grading.

Copyright by the American Water Works Association
Wed Feb 02 02:16:36 2005

3. A site geotechnical survey and foundation report, including logs of borings and test pits, soil densities, and other pertinent soil and geological information; construction criteria for any backfill that may be necessary at a particular site; and foundation design criteria prepared by a registered professional engineer specializing in soil mechanics, including allowable bearing loads, anticipated total and differential settlements, and the seismic soil profile type.

4. Structural loading conditions, including, but not limited to, snow, wind, seismic, hydrostatic uplift, and other live loads depending on the tank's intended use; the amount of earth cover over the tank, if any; the height of backfill against the tank wall, if any; and any other special loading conditions that are anticipated or special criteria on which the tank design is to be based. If, for example, the tank is located in a high-intensity earthquake area and must continue to serve without damage, the purchaser may specify an importance factor for earthquake design as described in Sec. 4.2.1 or provide design values for the peak horizontal ground acceleration and for the spectrum velocity. In cases where the static and dynamic earth pressures resulting from seismic shaking must be designed for, the purchaser shall provide the required geotechnical data to evaluate these pressures in the tank design. If the tank is to be located in seismic zones 3 or 4, additional information shall be provided in the soils report as discussed in Sec. 4.

5. Requirements for subdrainage and overflow collection systems.

6. Delivery of electric power and water service to the site.

III.B. *Purchaser Options and Alternatives.* The items that follow are either required information or alternative options in the standard that should be considered and covered in the purchaser's specifications, unless the purchaser intends that the choice for a particular option be left to the tank designer's discretion.

1. The standard to be used, that is, AWWA D110-95, Standard for Wire- and Strand-Wound, Circular, Prestressed Concrete Water Tanks.

2. The required capacity of the tank and desired height–diameter relationship.

3. The required elevation of the overflow weir and freeboard requirements.

4. The type of roof and type or types of tank wall. Basic wall types are listed in Sec. 1.1.1. Roof structures may be shotcrete or concrete domes as described in Sec. 3.6, nonprestressed concrete flat slabs supported by columns as described in Sec. 3.7.1.1, or other types of roofs selected by the purchaser. Preference for wet mix or dry mix for the tank wall or shotcrete cover coats, as specified in Sec. 2.1.2.2.

5. Maximum filling and emptying (overflow) rates required.

6. Size, material, arrangement, and location for the overflow pipe.

7. Size, material, location, details, cover depths, and limits of responsibility for all other pipe connections.

8. Requirements for subdrainage and overflow collection systems.

9. Finish grade relative to the tank foundation. (Whether or not the wall is to be completely exposed, partially buried, or completely buried.)

10. Tank appurtenances required.

a. Whether or not a removable silt stop is required and/or baffles are to be provided for circulation.

b. Size, material, and location of vents, access hatches, ladders, stairs, and manways; and locking and safety devices required.

c. Requirements for a water-level gauge or pressure sensor.

d. Specifications for any additional accessories to be provided.

Copyright by the American Water Works Association
Wed Feb 02 02:16:36 2005

11. Special exterior wall coatings or architectural treatment, if any.
12. Seismic information required.
a. Zone classification (Table 2 and Uniform Building Code*).
b. Importance factor (Table 3).
c. Soil profile coefficient (Table 5) from geotechnical survey report provided by the purchaser.
13. Special requirements, including federal, state, and local regulations, labor, and others.
14. Information on access to the site for the constructor's equipment and for supply of construction materials.
15. Availability and characteristics of electric power and source of water for construction.

III.C. *Modification to Standard.* Any modification to the provisions, definitions, or terminology in this standard must be provided in the purchaser's specifications.

IV. Major Revisions. This second edition of the standard has been edited throughout and includes revisions to standard definitions and terms adopted as Standards Council policy to achieve a higher degree of consistency among the standards produced by AWWA standards committees. This foreword has been arranged to address specific items in conformance with this policy.

Provisions for earthquake-induced forces, formerly attached to the standard as appendix A, provided for information only and not as a part of AWWA D110 in the first edition, has been incorporated into the standard as Sec. 4 and updated in accordance with experience and current practice.

The technical revisions to the standard reflect current thinking and construction practices. These include

1. Addition of a type IV core wall tank consisting of cast-in-place concrete with a steel diaphragm imbedded at the exterior face (Sec. 1.1.1).
2. Limitation of recommended use of the standard to containment of potable water and nonaggressive raw water (Sec. 1.1.3).
3. Clarification of terms to differentiate between wire- and strand-wound tanks addressed by this standard and tanks with a wall circumferentially prestressed using anchored tendons.
4. References to ASTM† A227 for prestressing wire or strand and to ASTM A586 and ASTM A603 for steel wire structural strand and wire rope have been deleted. (Sec. 1.3).
5. References to test methods ASTM C882, ASTM D395, ASTM D412, and ASTM D2240 have been deleted as they are referenced in the appropriate standard. Fed. Spec. TT-S-227 polysulfide sealant has also been deleted (Sec. 1.3).
6. References to ASTM standards A615, A641, A722, C920, and C1107 and to Fed. Spec. SS-S-210A have been added (Sec. 1.3).
7. For type II shotcrete core-wall tanks with a steel diaphragm, the requirement that the diaphragm be continuous for the full height of the tank, as currently practiced, has been added (Sec. 2.4.1.3).

Copyright by the American Water Works Association
Wed Feb 02 02:16:37 2005

8. Use of noncorrosive and noncontaminating chemical grout has been deleted and prohibition of the use of metallic nonshrinking aggregate grout for concrete repair has been added (Sec. 2.1.3 and Sec. 2.1.5).

9. The alternative approach of providing an initial prestress in the tank wall of 35,000 psi (240 MPa) in excess of the final prestress required for internal water pressure on the tank core wall with a minimum residual horizontal compression of 50 psi (345 kPa) in the core wall with the tank filled to the maximum overflow level has been deleted (old Sec. 3.4.2.3).

10. Rational design criteria for a dome tank cover has been modified to conform to standard practice (Sec. 3.6).

11. A requirement for a minimum 6-in. (150-mm) thick granular base material under a membrane floor has been added (Sec. 3.8.5).

12. Shotcrete floors have been deleted (Sec. 3.8.2).

13. A new section on tank appurtenances and accessories has been added (Sec. 3.11).

14. Requirements for hot-weather and cold-weather concreting and shotcreting have been clarified and modified (Sec. 5.2.1 and Sec. 5.3.1).

15. The allowable leakage for tank acceptance has been reduced to 0.05 from 0.1 percent of the tank capacity for a 24-h period (Sec. 5.13.2).

V. Comments. If you have any comments or questions about this standard, please call the AWWA Standards and Materials Development Department, (303) 794-7711, ext. 6283, FAX (303) 795-1440, or write to the department at 6666 W. Quincy Ave., Denver CO 80235.

ANSI/AWWA D110-95
(Revision of ANSI/AWWA D110-86)

AWWA STANDARD FOR

WIRE- AND STRAND-WOUND, CIRCULAR, PRESTRESSED CONCRETE WATER TANKS

SECTION 1: GENERAL

Sec. 1.1 Scope

1.1.1 *Intent of standard.* The intent of this standard is to cover current recommended practice for the design, construction, inspection, and maintenance of wire- and strand-wound, circular, prestressed concrete water-containing structures with the following four types of core walls:

type I—cast-in-place concrete with vertical prestressed reinforcement
type II—shotcrete with a steel diaphragm
type III—precast concrete with a steel diaphragm
type IV—cast-in-place concrete with a steel diaphragm

1.1.2 *Items not covered by standard.* This standard does not cover bonded or unbonded horizontal tendons for prestressed reinforcement of the tank wall, floor, or roof.

1.1.3 *Tank contents.* This standard applies to containment structures for use with potable water or raw water of normal temperature and pH commonly found in drinking water supplies. It is not intended for use in the design of containment structures for highly aggressive waters or high-temperature waters without special consideration being given to their effects on the structure; nor is it intended that the standard be used for the design of structures for wastewater, bulk dry storage, chemical storage, or storage of slurries.

Copyright by the American Water Works Association
Wed Feb 02 02:16:37 2005

Sec. 1.2 Definitions

In this standard, the following definitions will apply:

1.2.1 *Parties:* The persons, companies, or organizations generally involved in the purchase, design, and construction of circular, prestressed concrete tanks including:

1. *Bidder:* A party from whom bids for construction of the tank are solicited or received by the purchaser.

2. *Constructor:* The party that furnishes the work and materials for placement or installation in providing the tank for the purchaser.

3. *Design-constructor:* A firm that specializes in, designs, and constructs prestressed concrete tanks.

4. *Manufacturer:* A party that manufactures, fabricates, or produces materials or products.

5. *Prestresser:* The person, company, or organization that applies the prestressing forces to the tank.

6. *Purchaser:* The person, company, or organization that purchases any materials or work to be performed in the design and construction of the tank.

7. *Purchaser's engineering agent:* The registered professional engineer representing the purchaser in the design of the tank and/or during its construction.

1.2.2 *Capacity:* The net volume of contents that may be removed from a tank filled to the overflow level.

1.2.3 *Core wall:* That portion of the concrete or shotcrete wall that is circumferentially prestressed.

1.2.4 *Base and top-of-wall joints:* Connections between the base of the tank's core wall and its foundation or floor slab and between the top of the wall and roof slab or dome. Types of wall-base joints may be generally defined as follows:

1. *Unanchored and uncontained, free:* Minimal restraint of radial translation and rotation.

2. *Anchored flexible:* Minimum restraint of radial translation and rotation, employing strand anchor cables between the joint components to resist tangential displacement.

3. *Reinforced-nonsliding, fixed:* Considerable or full restraint of radial translation and rotation.

4. *Changing restraint:* A wall-base joint may be of a different type during and after prestressing. An example is a joint that is unrestrained during horizontal prestressing of the wall, but is hinged after prestressing. The change in joint type is a result of grout installation that prevents radial translation after prestressing.

Types of wall-roof joints in general use may be defined as follows:

1. *Separated:* Minimal restraint of radial translation and rotation.

2. *Hinged or pinned:* Full restraint of radial translation; negligible restraint of rotation.

3. *Reinforced nonsliding:* Fixed for restraint of radial translation and rotation.

1.2.5 *Membrane floor:* A thin, highly reinforced, low-moment-resistant, concrete slab-on-grade designed to be a flexible watertight floor system.

1.2.6 *Mortar and grout:* Includes the following types:

1. *Cement mortar:* Generally, a mixture of sand, cement, and water of specified proportions.

2. *Epoxy mortar:* A mixture of epoxy resin, catalyst, and fine aggregate for repair of concrete.

Copyright by the American Water Works Association
Wed Feb 02 02:16:38 2005

3. *Nonshrink grout:* A shrinkage-compensating, expansive cement grout used for concrete repair and patching of form-tie holes.

4. *Cement grout:* A portland cement and water mixture of pourable consistency (without segregation of constituents) used to bond and provide corrosion protection to prestressed tendons in a duct.

5. *Epoxy grout:* An epoxy-resin system used to bond and provide corrosion protection to vertical prestressed tendons in a duct.

6. *Epoxy bonding agent:* An epoxy resin normally used in repair processes to bond fresh plastic concrete mix, cement mortar, or epoxy mortar to hardened concrete.

1.2.7 *Prestressed concrete:* Concrete in which internal compressive stresses of such magnitude and distribution are introduced that the tensile stresses resulting from the service loads are counteracted to the desired degree; circumferential prestress of the tank wall is introduced herein by the helical application of high-strength steel wire or strand under controlled tension and vertical prestress by posttensioned, high-strength steel bar or strand tendons.

1.2.8 *Prestressed reinforcement:* High-strength steel used to prestress the concrete or shotcrete of the tank wall or dome roof edge ring, commonly single wires, seven-wire strands, or bars.

1. *Wire:* High-strength, cold-drawn steel wire used for prestressed reinforcement.

2. *Strand:* A symmetrically arranged and helically twisted assembly, commonly of seven high-strength steel wires, used for prestressed reinforcement or as nonprestressed earthquake cables.

3. *Tendon:* High-strength strand or bar, including end anchorages, used to impart vertical prestress to the tank wall.

1.2.9 *Duct:* Tubing for forming internal voids in the core wall for placement of vertical prestressed reinforcement.

1.2.10 *Shotcrete:* Pneumatically applied wet- or dry-mix mortar or concrete used for the core wall or as embedment and protection of the circumferential prestressed wall reinforcement, including

1. *Wire coat:* Initial application of shotcrete over the prestressed wire or strand.

2. *Cover coat:* Shotcrete applied over the wire coat of the outer layer of prestressed wire or strand.

3. *Finish coat:* The final layer of cover coat, usually placed for improved appearance.

1.2.11 *Specifications:* A statement describing the structure to be provided and containing the details of construction materials, methods, or contractor performance required in conjunction with the construction drawings and other contract documents for the structure.

1.2.12 *Standpipe:* A cylindrical structure for water storage, based at or below grade and having a wall height greater than its diameter. Standpipes are considered a special type of tank because of generally more critical loading conditions. Use of this standard in the design and construction of standpipes is not, however, precluded.

1.2.13 *Tank:* A cylindrical structure for water storage, based at or below grade. In general, this term shall refer to a structure having a wall height equal to or less than its diameter.

1.2.14 *Waterstop:* An impervious barrier installed to prevent passage of water through a construction or expansion joint between adjacent elements of concrete or shotcrete construction.

Copyright by the American Water Works Association
Wed Feb 02 02:16:38 2005

1.2.15 *Wire or strand winding:* The helical application of a continuous wire or strand for circumferentially prestressing the wall or dome ring of a circular tank.

SECTION 2: MATERIALS

Sec. 2.1 Concrete and Shotcrete

2.1.1 *General.* The quality of concrete or shotcrete is of great importance to its structural integrity and watertightness. Therefore, care shall be taken throughout the tank construction to maintain close quality control of the materials, proportions, forming, embedded items, placement, finishing, curing, and other details of the work. Concrete or shotcrete in potable-water tanks in contact with water shall

1. Be dense and low in permeability to retain water, to prevent contamination of the tank contents, and to avoid unsightly efflorescence and spalling.
2. Provide a noncorrosive environment for nonprestressed steel reinforcement, steel diaphragms, and prestressed steel reinforcement.
3. Provide a surface that is smooth and well formed to facilitate cleaning and reduce maintenance. Ordinary wall finish for concrete and a lightly broomed finish for shotcrete and precast panels are acceptable provided good workmanship standards are observed.

2.1.2 *Concrete and shotcrete materials.* Concrete and shotcrete materials shall conform to the recommendations of ACI 301, 350R, and 506.2 as modified herein. The mix proportions shall be submitted to the purchaser and shall meet the strength requirements of the purchaser's specifications. For corrosion protection of the steel reinforcement, concrete or shotcrete used in the core wall, top slab, or dome, and shotcrete for covering prestressed wire or strand, shall not contain water-soluble chloride ions in excess of 0.06 percent of the weight of the cement in the mix as determined by AASHTO T-260.

Concrete subjected to freeze–thaw cycling shall be air entrained in accordance with ACI 301. Wet-mix shotcrete for dome roofs in areas subjected to freeze–thaw cycles shall be air entrained with an air content of 5 to 8 percent at the pump. Dry-mix shotcrete shall not be used in domes subject to freezing cycles.

2.1.2.1 Shotcrete wire coat used for covering prestressed wire or strand shall consist of not more than three parts sand to one part portland cement by weight; additional coats of shotcrete shall consist of not more than four parts sand to one part portland cement by weight.

2.1.2.2 Either the wet-mix or dry-mix process referred to in ACI 506R may be used for shotcreting unless the specifications require the use of a specific process. Shotcrete shall be proportioned for a 28-day strength equal to that for which the core wall is designed, but not less than 4,000 psi (28 MPa) unless otherwise specified.

2.1.3 *Cement mortar.* Mortar used for repair of concrete, encasement of waterstop, and for patching form tie holes shall consist of not more than three parts sand to one part portland cement by weight and shall conform to the requirements of ACI 301. Mortar shall not contain water-soluble chloride ions in excess of 0.06 percent of the weight of the cement in the mortar. Shrinkage-compensating mortars (nonshrink grout) shall be of the nonmetallic type as specified in Sec. 2.1.5.

2.1.4 *Cement grout.* Cement grout used for grouted or bonded vertical tendons in ducts shall contain not more than 0.45 parts water to one part portland cement by weight (approximately 4.5 gal [17 L] per sack of cement) and shall not contain water-soluble chloride ions in excess of 0.06 percent of the weight of the cement in the grout. Cement grout for tendons shall contain admixtures to reduce bleeding and grout settlement, and shall be used in accordance with the manufacturer's recommendation for this application.

Copyright by the American Water Works Association
Wed Feb 02 02:16:39 2005

2.1.5 *Nonshrink grout.* Nonshrink cement grout used for repair of honeycomb and other concrete repair and for patching form tie holes shall be a nonhydrogen-gas-liberating, nonmetallic grout meeting all of the requirements of ASTM C1107, grade A or C, for nonshrink grout. This grout is not to be used for bonding of prestressed tendons, or in contact with the wire or strand prestressed reinforcement.

Sec. 2.2 Mixing Water

Mixing water shall conform to the requirements of ACI 318.

Sec. 2.3 Admixtures

Admixtures shall comply with the requirements of ACI 301 or ACI 506.2 and shall not contain more than trace amounts of chlorides, fluorides, sulfides, or nitrates because of their possible corrosive effect on the prestressed reinforcement. Materials in contact with potable water shall not impart taste, odor, or toxic chemicals to the water. All admixtures used in the concrete shall be compatible.

Sec. 2.4 Reinforcement

2.4.1 *Nonprestressed reinforcement.*

2.4.1.1 Deformed billet-steel bars; epoxy-coated steel bars; fabricated deformed steel bar mats; and steel welded-wire fabric, plain or deformed, for concrete reinforcement shall conform to the requirements of ACI 318 and the applicable ASTM standards referenced therein.

2.4.1.2 Strand for earthquake cables shall meet the requirements of ASTM A416, for seven-wire prestressing steel strand. The strand shall be protected with a fusion-bonded epoxy coating, grit-impregnated on the surface, conforming to ASTM A882/A882M, or it shall be galvanized. Galvanized strand shall meet the requirements of ASTM A416 prior to galvanizing. The zinc coating for galvanizing shall meet the requirements of ASTM A641/A641M or ASTM A475, with a minimum weight per unit area of uncoated wire surface of class A of these standards.

2.4.1.3 Steel-sheet diaphragms for use as impervious membranes in the walls of prestressed concrete tanks shall be vertically ribbed with adjacent and opposing channels. The base of the channels (see Figure 1) shall be wider than the throat, thus providing a mechanical keyway anchorage between the inner and outer concrete or shotcrete. Uncoated steel sheet shall comply with ASTM A366, and hot-dipped galvanized sheet shall comply with ASTM A525. Diaphragm steel thickness shall be a minimum of 0.017 in. (0.43 mm). Weight of zinc coating, where specified, shall be not less than G 90 of Table 1 of ASTM A525. The diaphragm sheets shall be continuous for the full height of the tank.

2.4.2 *Prestressed reinforcement.*

2.4.2.1 Uncoated prestressing wire and strand shall conform to the requirements of ACI 318 and the following applicable ASTM standards: hard-drawn steel wire to be helically wrapped, maintaining tension by mechanical means, shall conform to the requirements of ASTM A821; ASTM A648, class II; or ASTM A421, type WA. Steel wire, hard-drawn to be helically wrapped on the structure employing a wire drawing die for back tension, shall conform to the requirements of ASTM A821. Steel prestressing strand shall conform to the requirements of ASTM A416.

2.4.2.2 Galvanized prestressing wire and strand to be helically wrapped and tensioned shall meet the requirements of ASTM A821; ASTM A648, class II; or ASTM A421, type WA, for wire, and ASTM A416 for strand. Zinc coating for galvanizing

Copyright by the American Water Works Association
Wed Feb 02 02:16:40 2005

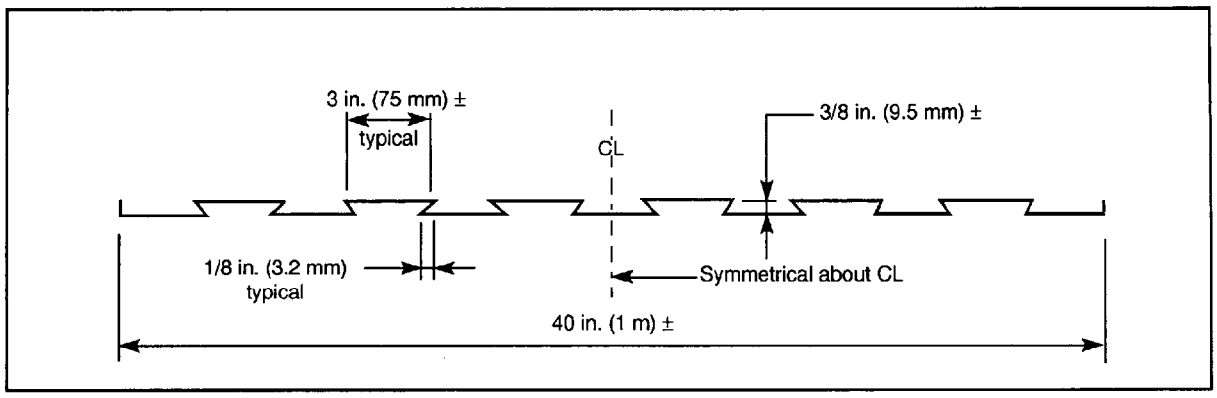

Figure 1 Example diaphragm sheet

shall meet the requirements of ASTM A641/A641M or ASTM A475, with a minimum weight per unit area of uncoated wire surface of 0.85 oz/ft^2 (259 g/m^2) or of class A of these standards.

Where galvanized wire is stressed on the structure by drawing through a die, the zinc coating remaining after stressing shall be a minimum of 0.50 oz/ft^2 (150 g/m^2) of wire surface.

2.4.2.3 Splices for horizontal prestressed reinforcement shall be ferrous material compatible with the reinforcement and shall develop the full strength of the wire or strand. Anchor clamps and other accessories in contact with the prestressing elements may be galvanized or epoxy-coated iron or steel. Wire splice and anchorage accessories shall not weaken or otherwise compromise the prestressed reinforcement.

2.4.2.4 Tendons for vertical prestressed reinforcement of cast-in-place concrete core walls shall consist of high-strength strand or bars conforming to the requirements of ACI 318 and the material requirements of ASTM A416 or ASTM A722. Tendon anchorages may be galvanized or epoxy coated for additional corrosion protection.

2.4.3 *Steel corrosion inhibitor.* Temporary corrosion protection of vertical prestressed reinforcement left in the ducts for more than 10 days prior to grouting shall be provided by volatile or vapor-phase inhibitors. These inhibitors are applied in solid form (a fine white powder) or liquid form that vaporizes and coats the surface of the prestressing steel with a stable organic nitrate that prevents corrosion by passivating the metal. The corrosion inhibitor shall have no deleterious effect on the steel or bond strength between the cement or epoxy-resin grout and steel, and shall not prevent future corrosion protection of the prestressing steel by the grout.

Sec. 2.5 Elastomeric Materials

2.5.1 *Waterstops.* Waterstops shall be composed of plastic or other materials suitable for the intended use.

2.5.1.1 Plastic waterstops. Plastic waterstops shall be of virgin polyvinyl chloride meeting the requirements of CRD-C572. Splices shall be made in accordance with the manufacturer's recommendations, subject to review by the purchaser. Tests assuring conformity to the specification shall either be made on material delivered to the jobsite or be certified by an independent testing laboratory. Plastic waterstops shall be ribbed and shall have a minimum ultimate tensile strength of 1,750 psi (12.17 MPa), ultimate elongation of 300 percent, and a shore hardness of 70 to 80 durometer.

Copyright by the American Water Works Association
Wed Feb 02 02:16:40 2005

AWWA D110 95 ■ 0783350 0502969 920 ■

2.5.2 *Bearing pads.* Bearing pads used in the floor-to-wall and wall-to-roof joints shall consist of neoprene, natural rubber, or polyvinyl chloride.

2.5.2.1 Neoprene bearing pads shall have a minimum ultimate tensile strength of 1,500 psi (10.5 MPa), a minimum elongation of 500 percent, a maximum compressive set of 50 percent, and a hardness of 40 to 50 durometer in accordance with ASTM D2240. Neoprene bearing pads shall contain only virgin crystallization-resistant polychloroprene as the raw polymer and the physical properties shall comply with ASTM D2000, line call out 2BC415A14B14 for 40 durometer material.

2.5.2.2 Natural-rubber bearing pads shall contain only virgin natural polyisoprene as the raw polymer, and the physical properties shall comply with ASTM D2000, line call out 4AA420A13.

2.5.2.3 Polyvinyl chloride for bearing pads shall meet the requirements of CRD-C572 for tanks in cold-weather regions.

2.5.3 *Sponge filler.* Sponge filler shall be closed-cell neoprene or rubber conforming to ASTM D1752, type 1, or to the requirements of ASTM D1056, types 2A1 through 2A4.

Sec. 2.6 Duct Material

2.6.1 *Grouted tendons.* Duct material for grouted vertical wall tendons shall be flexible or semiflexible steel or polyvinyl chloride pipe or tubing and shall be sufficiently strong to retain its shape and location during placement and vibration of the concrete. Inside diameter of the duct to be filled with portland-cement grout shall be a minimum of 3/8 in. (9.5 mm) greater than the nominal diameter of the bar tendon, or the inside area of the duct shall be twice the area of the prestressed strand tendon. If the duct is to be filled with pumped epoxy, the annular space around the tendon may be reduced to the minimum size that will permit easy insertion of the tendon. Ducts shall be so constructed and sealed as to positively prevent the entrance of cement paste from the concrete and shall be equipped with suitable fittings and tubing at the base and top for flushing and pumping the grout or epoxy.

2.6.2 *Bonded tendons.* Duct material for fully bonded vertical tendons shall be semiflexible steel or corrugated polyvinyl duct. In addition to the requirements of Sec. 2.6.1, the duct shall be capable of transferring the stress from the tendon by bond or shear through the duct to the concrete along its full length.

Sec. 2.7 Concrete and Shotcrete Coatings

2.7.1 *Above grade.* In some cases, such as tanks located in areas subject to salt spray or other corrosive environments, coatings may be desired to seal the exterior surface of above-grade concrete and shotcrete dome roofs and shotcrete protection for the circumferential prestressed reinforcement. Coatings suitable for sealing the exterior of the tank shall be permeable to water vapor. Suitable coatings include rubber base (polyvinyl chloride–latex and polymeric vinyl–acrylic), acrylic elastomer and acrylic emulsion paints, and cementitious waterproofing compounds.

2.7.2 *Below grade.* Coatings are recommended for sealing the exterior surface of below-grade tanks where additional protection against aggressive soils is required. Coatings suitable for sealing the exterior of the tank wall include coal-tar epoxies and bitumastic compounds specifically formulated for this purpose.

2.7.3 Additional information on exterior coatings and seal coats for aggressive environments may be found in ACI 515.1R.

Copyright by the American Water Works Association
Wed Feb 02 02:16:41 2005

Sec. 2.8 Sealants and Joint Fillers

2.8.1 *Sealant for steel diaphragm joints.* Joints shall be sealed with polysulfide or polyurethane sealant, epoxy sealant, or double folded with a mechanical seamer, and shall be watertight under full tank head.

2.8.2 Polysulfide sealant shall be a two- (or more) component elastomeric compound of the appropriate type meeting the requirements of ASTM C920, type M, and shall have permanent characteristics of bond-to-metal or concrete surfaces, flexibility, and resistance to extrusion due to hydrostatic pressure. Air-cured sealants shall not be used. The grade and class shall be appropriate for the intended use as recommended by the manufacturer.

2.8.3 Polyurethane elastomeric sealant used in interior tank construction joints and movement joints at the base of the wall, or in floor or roof slab joints shall meet the requirements of ASTM C920, class 25, of appropriate type and grade for permanent bond-to-concrete surfaces, flexibility, and resistance to extrusion due to hydrostatic pressure. The sealant shall be multicomponent type M, of grade P for pourable, and grade NS for nonsag or gunnable. Sealant shall not impart taste, odor, or toxic chemicals to potable water.

2.8.4 Preformed bitumen compound plastic joint filler for use in exterior movement joints shall be of the appropriate type conforming to Fed. Spec. SS-S-210A. Such filler or sealing compound shall not be used in interior floor, wall, or roof joints in contact with potable-water tank contents, or where the material may leach into the tank contents.

2.8.5 Epoxy sealants shall be suitable for bonding to concrete, shotcrete, and steel, and shall be suitable for sealing the vertical joints between sheets of steel diaphragms. Epoxy sealants shall conform to the requirements of ASTM C881, type III, grade 1, and shall be a 100 percent solids, moisture-insensitive, low-modulus epoxy system. When pumped, maximum viscosity of the epoxy should be 10 poises (1 Pa·s) at 77°F (25°C), or shall be otherwise acceptable to the purchaser.

2.8.6 Polyurethane filler used to fill voids between components in the wall-base joint and seal around waterstops, base pads, seismic cable sleeves, and sponge fillers shall meet the requirements of ASTM C920, class 25, for single-component sealer type S, grade P or NS, as appropriate for the intended use.

Sec. 2.9 Epoxy Bonding Agent

Epoxy resin used for increasing the bond of fresh, plastic concrete or mortars to hardened concrete shall be a two-component, 100 percent solids, moisture-insensitive epoxy adhesive meeting the requirements of ASTM C881, type II, grade 2, as specified in ACI 503.2. The bonding agent shall produce a bond strength, as determined by ASTM C882, greater than 1,500 psi (12.2 MPa) 14 days after the plastic concrete is placed. Epoxy in contact with potable water shall not impart taste or odor, or leach toxic trace elements into the water.

Sec. 2.10 Epoxy Mortar and Grout

2.10.1 Epoxy mortar used for concrete repair shall be a noncorrosive and noncontaminating mixture of epoxy resin, catalyst, and fine aggregate proportioned in strict accordance with the manufacturer's instructions for the product and its intended use.

2.10.2 Epoxy-resin grout used for corrosion protection of prestressed vertical tendons or for bonding the reinforcement within the duct shall be a two-component,

Copyright by the American Water Works Association
Wed Feb 02 02:16:41 2005

moisture-insensitive, resin bonding system conforming to ASTM C881, of the type, grade, and class recommended by the manufacturer as suitable for these applications.

Sec. 2.11 Form Coatings

The form coating for concrete surfaces that will be in contact with potable water or that may leach trace elements into potable-water tank contents shall be of an organic base and shall be nonstaining and nontoxic.

SECTION 3: DESIGN

Sec. 3.1 Notation*

Symbols used in various equations presented in Sec. 3 are defined as follows:

A_{ds} = total area of prestressing wires or strand for dome ring (area, in.^{2}), see Sec. 3.6.5.1
d = distance from face of support (linear, in.)
E_c = short-term modulus of elasticity of concrete or shotcrete (force per unit area, psi)
f'_c = specified 28-day compressive cylinder strength of concrete or shotcrete (force per unit area, psi). (Refer to Sec. 5.3.4 for control of shotcrete strength)
f_c = permissible compressive concrete or shotcrete stress (force per unit area, psi)
f'_{ci} = specified compressive cylinder strength of concrete or shotcrete (Refer to Sec. 5.6.2.5) at time of prestressing (force per unit area, psi)
f_{pu} = specified ultimate tensile strength of steel prestressing wire, strand, or high-strength bars (force per unit area, psi)
f_{se} = effective stress in prestressed reinforcement after losses (force per unit area, psi)
f'_{si} = allowable initial stress in prestressed reinforcement before losses (force per unit area, psi)
f_t = flexural tensile stress in extreme fiber of the core wall (force per unit area, psi)
l_d = development length for bond (linear, in.)
L = unit live load on dome shell (force per unit area, lb/ft^2)
P_{fw} = final prestressing force for water load (force, lb)
P_u = factored (uniformly distributed) unit dead and live design load on dome shell (force per unit area, lb/ft^2)
r_d = mean radius of dome shell (linear, ft)
r_i = average maximum radius of curvature over a dome imperfection area (linear, ft)
t_c = core-wall thickness (linear, in.)
t_d = dome-shell thickness (linear, in.)
u = nominal bond stress in concrete or shotcrete (force per unit area, psi)

*Caution should be used to be consistent throughout with use of units.

Copyright by the American Water Works Association
Wed Feb 02 02:16:42 2005

V_c = nominal shear stress in concrete or shotcrete (force per unit area, psi)
V_{max} = maximum shear stress in reinforced section (force per unit area, psi)
W = total dead and live load on dome, exclusive of dome ring (force, lb)
β_c = buckling reduction factor for creep, nonlinearity, and cracking of concrete
β_i = buckling reduction factor for geometrical imperfections from a true spherical surface, such as local increases in radius
ω = half central angle of dome shell (degrees)
ϕ = strength reduction factor

Sec. 3.2 Design Method

Tank design shall be based on elastic analysis methods and shall take into account effects of all loads and prestressing forces during and after tensioning, and conditions of edge restraint at wall junctions with floor and roof. Stresses shall not exceed allowable service stresses described in Sec. 3.4. Consideration shall also be given to the effects of all loads and load combinations, including stresses induced by temperature and moisture gradients. The recommendations herein pertain to service-load conditions and serviceability requirements. For many effects, the service-load design is more conservative than the strength design. However, to ensure the safety of the structure, the design must also meet the strength requirements of ACI 318. All applicable sections of the latest edition of ACI 318, including supplements and the chapters describing precast and prestressed concrete, shall be followed except when supplemented or modified by provisions of this standard.

Sec. 3.3 Design Loads

Loads indicated in this section are those most frequently encountered in prestressed concrete tank design and shall be included in the design calculations. Loadings, including prestressing forces and their placement, shall follow governing codes.

3.3.1 *Wall design loads.*

3.3.1.1 Internal pressure—the pressure from water at maximum overflow level.

3.3.1.2 Backfill loading—the lateral pressure from earth backfill, symmetrical or asymmetrical. Net lateral loads, including those due to unequal backfill, shall be determined by rational methods of soil mechanics based on foundation and soils investigations. Surcharge loads on backfilled surfaces shall be considered.

Backfill pressure shall not be used to reduce the amount of prestressing force required for resisting internal water pressure. Backfill forces shall be based on soil parameters established by a professional engineer experienced in soils.

3.3.1.3 Minimum design loadings for wind and earthquake. These loadings shall conform to requirements of local building codes and the provisions of the seismic sections of the ICBO *Uniform Building Code* or ANSI/ASCE Standard 7-88. Seismic design criteria for prestressed concrete tanks are set forth in Sec. 4 as appropriate.

3.3.1.4 Effects of construction, including loads resulting from equipment, materials, and construction methods to be used.

3.3.1.5 External hydrostatic pressure on the floor and wall, if any.

3.3.1.6 Appurtenance loads.

3.3.1.7 Operating loads and system surges.

3.3.1.8 Thermal and moisture gradients as follows:

1. Radially, through the thickness of the wall.
2. Vertically, that occur between the buried and exposed portion of the wall.

Copyright by the American Water Works Association
Wed Feb 02 02:16:42 2005

3. Between the wall and roof or floor.

3.3.1.9 Effects on the wall due to application of prestressing forces, including those due to nonlinear distribution of prestressing forces temporarily induced during the stressing operations and in the completed structure.

3.3.2 *Roof design loads.*

3.3.2.1 Dead loads, including sustained surcharges.

3.3.2.2 Earth, snow or ice, and other live loads.

3.3.2.3 Construction loads.

3.3.2.4 Wind loads.

3.3.2.5 Earthquake loads.

3.3.2.6 Appurtenance loads.

3.3.2.7 Operational loads, if any.

3.3.2.8 Roof openings.

3.3.3 *Floor design loads.*

3.3.3.1 Dead loads.

3.3.3.2 Water loads.

3.3.3.3 Earthquake loads.

3.3.3.4 Uplift due to groundwater or expansive soils.

3.3.3.5 Radial forces from the base of the tank wall.

3.3.3.6 Differential and total settlement.

3.3.4 *Control of loads.* Consideration shall also be given to the following load control techniques and their safety margins:

3.3.4.1 Overflow systems.

3.3.4.2 Venting.

3.3.4.3 Internal freeboard to provide room for sloshing during an earthquake.

3.3.4.4 Perimeter and underfloor drainage systems to limit hydrostatic pressures.

3.3.4.5 Provisions for drainage of surface water from earth backfill and roof runoff away from the structure, or use of a free-draining granular backfill adjacent to the wall, should be considered for reducing lateral loading on the exterior face of the tank wall.

Sec. 3.4 Allowable Stresses

3.4.1 *Concrete and shotcrete.* Service-load stresses shall be limited to provide protection against leakage into or out of the tank and against corrosion of the reinforcement. Concrete cracking shall not be allowed under predominantly axial stresses. Cracking under predominantly flexural stresses shall be controlled to limit crack depth and width. The stresses for concrete and shotcrete shall not exceed the values indicated in Table 1.

3.4.2 *Prestressed reinforcement.*

3.4.2.1 Maximum permissible initial stress f_{si} in any wire or strand on the wall, or in vertical threaded bar prestressed reinforcement shall not exceed 0.75 f_{pu}. Maximum initial stress for anchored strands in vertical prestressed reinforcement, after anchorage losses, shall not exceed 0.70 f_{pu}.

3.4.2.2 Long-term stress losses due to shrinkage and creep of concrete or shotcrete, and relaxation in prestressed reinforcement shall be calculated in accordance with the recommendations in Reference 18.6 of ACI 318 or assumed to be 25,000 psi (170 MPa). Calculation of stresses due to thermal and moisture gradients may normally be ignored if the initial prestress provides for these long-term losses and, in addition, produces a residual horizontal compression in the concrete or shotcrete core wall, with

Table 1 Allowable stresses in concrete and shotcrete

Description	Notation	Allowable Stresses*
Compression: Horizontal or vertical in extreme fiber.	f_c	0.55 f_c' initial; 0.45 f_c' final.
Tension: Vertical, in extreme fiber of all nondiaphragm tanks. All nondiaphragm tanks shall be vertically prestressed.	f_t	Vertical flexural tensile stresses to be reduced to zero by vertical prestressing as in Sec. 3.5.3 or taken by the auxiliary nonprestressed reinforcement at the stresses in paragraphs of Sec. 3.4.3.
Tension: Vertical in diaphragm tanks.	f_t	100 percent of the tensile force shall be taken by the reinforcing steel and/or diaphragm at the stresses specified in the paragraphs of Sec. 3.4.3.
Shear: As a measure of diagonal tension at a distance d from the face of the support, psi.		
Members with no web reinforcement.	V_c	$1.1\sqrt{f_c'}$
Members with vertical or inclined web reinforcement.	V_{max}	$5\sqrt{f_c'}$ (Increased stress allowed for properly designed reinforcement.)
Slabs with footings—peripheral shear.	V_c	$2\sqrt{f_c'}$
Bond: Development length and bonding reinforcement:		
Deformed bars and welded wire fabric.	l_d	Development length l_d shall be computed as a measure of bond resistance in accordance with recommendations of ACI Committee 318.
Steel diaphragm	u	$2.5\sqrt{f_c'}$ (See Sec. 3.4.3.3.)

*Coefficients shown are for values of f_c' expressed in pounds per square inch (psi). Refer to Sec. 3.1 for definition of symbols in notations.

the base free to move radially, of not less than 200 psi (1.4 MPa) above ground tapering linearly to 50 psi (340 kPa) at 6 ft (1.8 m) below ground with the tank filled to the maximum overflow level. For restrained base-joint construction, the equivalent prestress force shall be provided as if the base were free to move radially.

3.4.2.3 Maximum design stress in prestressed wire, strand, or high-strength bars f_{se} for structures subject to full design load, after deduction of the above allowances for stress losses, shall not exceed 0.65 f_{pu}.

3.4.3 *Nonprestressed reinforcement.*

3.4.3.1 Nonprestressed reinforcement shall be designed in accordance with the requirements of Alternate Design Method, in ACI 318. The strength requirements of ACI 318 shall also be satisfied. Since crack control is of paramount importance to prestressed concrete structures, more conservative allowable steel stresses are recommended than used in building construction, and additional nonprestressed reinforcement is often used in areas of localized stress to control cracking and preclude the contained liquid from reaching the prestressing elements. Low stress in reinforcement at service loads is good insurance against undesirable performance of these structures. Recommended maximum stresses and spacing for deformed bars, as provided in ACI 350R, shall not be exceeded.

3.4.3.2 Nonprestressed reinforcement may consist of bars or welded wire fabric. The area of steel-sheet wall diaphragm parallel to the direction of its channels (vertical)

Copyright by the American Water Works Association

AWWA D110 95 ■ 0783350 0502975 124 ■

may also be used to contribute to the vertical reinforcement of the wall provided the diaphragm is located close enough to the inside or outside surface to effectively control cracking due to vertical bending moments.

3.4.3.3 For diaphragm-type tanks, the allowable tensile stress in the diaphragm shall not exceed 18,000 psi (120 MPa). Design shall otherwise be in accordance with the requirements of ACI 350R.

3.4.3.4 Nonprestressed steel reinforcement shall not be used to resist any portion of circumferential tension in the wall. It may be used to resist circumferential tension in the dome-roof edge ring due to roof live load as provided in Sec. 3.6.5.2.

Sec. 3.5 Wall Design

3.5.1 *Design calculations.* Wall design shall be based on elastic cylindrical-shell analyses for stresses and deformations due to loads outlined herein. The design calculations made by either the purchaser's engineer, a retained consultant, or the design-construct contractor shall be made a matter of record, available at the request of the purchaser and approving authority.

3.5.2 *Circumferential prestressing force.* Circumferential prestressed reinforcement shall be furnished to resist all forces due to internal loads, after accounting for all stress losses and for residual compression.

3.5.2.1 The minimum final circumferential prestressing force to contain the water load at any point on the wall shall include provision for the calculated forces for thermal and moisture gradients or allowance for a minimum residual compression of 200 psi (1.4 MPa) for the aboveground portion of the tank wall, tapering linearly to 50 psi (340 kPa) at 6 ft (1.8 m) below grade as specified in Sec. 3.4.2.2. For empty open-top tanks, the final horizontal prestress force, after losses, shall provide 400 psi (2.8 MPa) minimum compression in the concrete or shotcrete core wall at any point on the wall. For a tank covered with a concrete roof that is monolithic with or bears on and restrains the top of the wall, the final horizontal prestress force, after losses, for the empty tank shall provide 240 psi (1.7 MPa) minimum compression at any point in the core wall when free joints are assumed at the top and bottom.

3.5.3 *Vertical prestressing force.*

3.5.3.1 In nondiaphragm tanks, vertical prestressed reinforcement shall be provided to produce, after allowance for prestress losses, a minimum axial average compression of 200 psi (1.4 MPa) in the concrete core wall. Looped strand tendons shall not be used. Vertical tendons shall have end anchors at the top and bottom of the wall. The maximum spacing of vertical tendons shall not exceed seven times the wall thickness or 50 in. (1.3 m), whichever is less. Auxiliary nonprestressed steel reinforcement shall be provided to resist part of the vertical bending moments resulting from edge restraint, differential dryness and temperature, and other applied loads. For example, vertical nonprestressed reinforcement may be required at the lower portion of the wall (inside face) to control concrete tension as the circumferential prestressing is applied.

3.5.4 *Core-wall thickness.* The thickness of the concrete or shotcrete core wall t_c, prior to prestressing, shall be such that membrane shell stresses are within the allowable stresses; the minimum dimensional limits are as follows:

8 in. (200 mm) for type I core walls,
3 ½ in. (90 mm) for type II core walls,
4 in. (100 mm) for type III core walls, and
7 in. (180 mm) for type IV core walls.

Copyright by the American Water Works Association
Wed Feb 02 02:16:43 2005

3.5.4.1 For tanks with unusual dimensions, unusual vertically applied loads, or other unusual loading, minimum wall thickness shall be based on analyses that include an evaluation of wall stability, buckling, and moments introduced by prestressing and other forces.

3.5.4.2 For core walls with a diaphragm, the diaphragm shall be embedded with a minimum of 1.0 in. (25 mm) interior cover. For all core walls incorporating a diaphragm at the exterior face of the wall, at least 0.5 in. (13 mm) of shotcrete cover shall be applied to the exterior of the steel diaphragm prior to wire or strand wrapping to fill the diaphragm channels or flutes and preclude wrapping the horizontal prestressed reinforcement directly on the exposed steel diaphragm.

3.5.5 *End restraint.* Restraint of the wall at either the base or roof causes significant vertical bending stresses that must be evaluated and included in the design.

3.5.5.1 Wall-joint details. The designer shall consider all wall boundary conditions resulting from the construction-joint details to be used at the top and bottom of the wall. Particular attention shall be given to restraint of translation and rotation, which varies depending on whether the joint is monolithic, allowed to slide (friction force), or allowed to move by deforming an elastomeric pad (rigidity of the pad) (see Sec. 4.2.1). Use appropriate values of recognized test data and record the values in the project calculations. For guidance to the designer, the *Handbook of Molded and Extruded Rubber,* second edition, provides data on rubber pads for various durometers of hardness and shape factors.

3.5.6 *Vertical nonprestressed reinforcement.*

3.5.6.1 Tank core walls reinforced vertically with only nonprestressed steel reinforcing shall contain a suitable watertight steel diaphragm. In the diaphragm wall, nonprestressed reinforcement shall be used to resist the vertical flexural tension caused by edge restraints when either internal water pressure, external loadings, or circumferential prestressing are applied. The diaphragm may preclude the necessity for additional nonprestressed reinforcement in free base tanks and for effects resulting from temperatures and moisture gradients where the wall is a thin section and temperature conditions are not extreme. A minimum vertical-reinforcement ratio of 0.0025 on each face of the wall section shall be provided by the diaphragm and auxiliary nonprestressed reinforcement.

3.5.6.2 Maximum tensile stress for regular nonprestressed steel reinforcement used to resist vertical bending stresses due to service loads shall be 18,000 psi (120 MPa) for grades 40, 50, and 60. Bar size shall be no greater than 3/4 in. (19 mm) (No. 6) and bar spacing shall not exceed 12 in. (300 mm). The cross-sectional area of the steel diaphragm used in a tank core wall may be included as part of the nonprestressed vertical steel reinforcing requirements provided that the steel stress does not exceed 18,000 psi (120 MPa) and the diaphragm is close enough to the face of the wall to control cracking due to bending moments in the wall.

3.5.6.3 The minimum concrete or shotcrete interior cover over steel diaphragms, welded wire fabric, and bar reinforcement shall be not less than 1 in. (25 mm) or one and a half times the diameter of nonprestressed steel deformed bars, whichever is greater. Cover for vertical tendon anchorages shall not be less than 2 in. (50 mm). For containment of aggressive water, additional cover shall be provided for the reinforcement.

3.5.7 *Seismic forces.* Forces and moments resulting from seismic accelerations of water loads, dead loads, and external loads shall be taken into account in the design, except where the tank is to be constructed in a zero seismic zone area. The

Copyright by the American Water Works Association
Wed Feb 02 02:16:44 2005

AWWA D110 95 ■ 0783350 0502977 TT7 ■

design shall include the construction details to be provided at the top and base of the wall. Seismic cables, shear keys, dowels, elastomeric pads with or without confinement ring joints, and monolithic joints are examples of systems available to resist these forces. Stresses and deflections produced by seismic effects in all components shall be controlled. These may be determined and evaluated using the provisions in Sec. 4.

3.5.8 *Shear forces.* Reinforcement of joints must be sufficient to resist the following loads and any combination thereof:

1. Water.
2. Backfill.
3. Seismic.
4. Prestressing.
5. Other.

3.5.9 *Bearing pads.* In order to minimize vertical bending moments in the wall, it is important to keep the hardness in the range of 30 to 50 durometers and the pad thickness under the wall at a ¾-in. (18-mm) minimum. When a pad is required between the wall and roof, it shall have a minimum thickness of ½ in. (13 mm). The required pad area is determined after considering the vertical load, percent compression, and allowable deformation of the pad.

Sec. 3.6 Dome-Roof Design

3.6.1 *General.* A number of different types of concrete and shotcrete dome designs have been successfully used as covers for prestressed concrete tanks. The most common types used today in the United States are spherical shells of cast-in-place or precast concrete. The joint between the dome edge ring and the top of the wall may be "fixed" by extension of the wall reinforcement to restrict radial translation and rotation, "pinned" to restrain against translation, or "separated" by an elastomeric bearing pad to minimize restraint of both translation and rotation (see Figure 2).

The dome roof may also be constructed of doubly curved, precast concrete panels. The panels are connected at cast-in-place intermediate circumferential rings and a dome edge ring. The pinned-type joint of Figure 2B is generally used with precast concrete and cast-in-place domes and the other two types of joints with cast-in-place domes. Provision must be made in the design of the fixed connection of Figure 2A for the effects of stress transfer from the dome to the wall and from the wall to the dome as discussed in Sec. 3.6.4. When the dome ring is separated from the tank wall, as in Figure 2C, the joint design may require means to prevent lateral displacement of the dome due to seismic activity, as discussed in Sec. 3.6.5.5.

3.6.1.1 Most concrete or shotcrete domes built in the United States are low-rise spherical shells with rise-to-span ratios between 1:12 and 1:8. Domes with greater rise-to-span ratios than 1:8 present a problem in placement and finishing at the edge without use of a top form, and ratios of 1:12 or less require larger edge ring prestress and are generally less economical. A rise-to-span ratio of 1:10 is typical.

3.6.1.2 Consideration shall be given in the dome design for severe exposure conditions and condensation on the underside of the roof. For this reason, dry-mix shotcrete shall not be used in construction of domes in areas subject to freeze–thaw cycles.

3.6.1.3 The cast-in-place concrete, precast concrete, and shotcrete dome designs described herein are for typical dome roofs commonly used in current practice. It is not the intent of this standard to preclude other dome-to-wall connections and alternative

AWWA D110 95 ■ 0783350 0502979 87T ■

cast-in-place dome designs that are in conformance with currently accepted standards, and that have been developed and successfully used in the United States.

3.6.2 *Design method.* Concrete or shotcrete dome roofs shall be designed on the basis of elastic shell analysis. A circumferentially prestressed dome edge ring or its equivalent shall be provided at the base of the dome shell if required to resist the horizontal component of the dome thrust.

3.6.3 *Thickness and reinforcement.* Dome shell thickness is governed by either buckling resistance, by minimum thickness for practical construction, or by corrosion protection of the reinforcement. Minimum thickness of concrete or shotcrete domes shall not be less than 3 in. (75 mm).

3.6.3.1 A method for determining the minimum thickness of a concrete spherical dome shell to provide adequate buckling resistance is given in appendix A, Zarghamee and Heger (1983). This method is based on the elastic theory of dome shell stability with consideration of the effects of creep, imperfections, and experience with existing tank domes having large radius-to-thickness ratios. Based on these criteria, the minimum recommended dome thickness for buckling may be determined from Eq 3-1.

$$\min\ t_d = r_d \sqrt{\frac{1.5P_u}{\phi\,\beta_i\,\beta_c\,E_c}} \qquad \text{(Eq 3-1)}$$

Refer to Sec. 3.1 for definition of symbols.

The conditions that determine the factors β_i and β_c are discussed in Zarghamee and Heger (1983). The values for these factors, which are given below, are recommended for use when domes are designed for conditions where live load is 12 lb/ft^2 (575 MPa) or more, water is stored inside the tank, dome thickness is 3 in. (75 mm) or more, f'_c is 3,000 psi (20.7 MPa) or more, normal-weight aggregates are used, and dead load is applied (i.e., shores removed) not earlier than seven days after concrete placement, with curing as required in ACI 301. Recommended values for the terms for such domes are

P_u = the minimum load factors given in ACI 318 for dead and live (snow) load, L

ϕ = 0.7

β_i = $(r_d/r_i)^2$, where r_i = averaged maximum radius of curvature over a dome imperfection area with a diameter of 2.5 $(r_d t_d)^{0.5}$

In the absence of other criteria, the maximum r_i may be taken as 1.4 r_d and in this case

β_i = 0.5

β_c = $0.44 + 0.003L$ for live loads between 12 and 30 lb/ft^2

β_c = 0.53 for live loads of 30 lb/ft^2 or greater

E_c = 57,000 $(f'_c)^{0.5}$ for normal-weight concrete or shotcrete

Precast concrete panel dome shells may be used in dome construction provided they are watertight and the designer makes allowance for joints between panels that are not equivalent in thickness, strength, or resistance to buckling to a monolithic shell.

3.6.3.2 The area of reinforcing steel in a dome, excluding the dome ring, shall be not less than 0.25 percent of the concrete cross-sectional area (0.0025 bt_d) in both the circumferential and radial directions. The reinforcement shall be placed approximately at the mid-depth of the shell, except in the edge region, where two layers of reinforcement shall be used in the radial direction.

Copyright by the American Water Works Association
Wed Feb 02 02:16:45 2005

3.6.4 *Dome edge region.* The edge region of the dome and the top region of the wall are subject to bending stresses that arise because deflections at the intersection of the dome ring and cylindrical wall differ from the membrane condition due to the dome and wall prestress and loading conditions. These stresses can be reduced to levels that do not impair tank performance by the proper design of the dome-wall joint as described in this section. Factors that affect bending stresses are type of joint (reinforced nonsliding, pinned, or separated), size of dome ring, initial prestress force on the ring and on the adjacent wall, and the thickness of the dome edge region. The edge effects may require thickening of the dome near its edge, radial reinforcement in the top and bottom of the dome edge region, and vertical reinforcement in each face of the upper tank wall.

3.6.5 *Dome edge ring.* Circular prestressing of the dome edge ring is used to eliminate or control circumferential tension in the dome ring and to minimize edge bending effects in the dome and upper region of the tank wall.

3.6.5.1 Unless a more accurate analysis is made, the area of prestressing steel to resist total dead and live load W shall be taken as

$$A_{ds} = \frac{W \cot\omega}{2 \pi f_{se}} \qquad \text{(Eq 3-2)}$$

See Sec. 3.1 for definition of symbols.

3.6.5.2 Prestressing force may be provided to counteract only that tension due to dead load plus all losses. If prestressing for less than the full live load is used, sufficient area of prestressing steel must be maintained at reduced stress, or additional nonprestressed reinforcing shall be added to provide strength in accordance with the requirements of ACI 318. Prestressing in excess of that required for dead-load thrust increases bending and compression stresses in the dome ring, in adjacent regions of the dome, and in the upper part of the wall when it is monolithic with the ring.

3.6.5.3 The dome edge ring is often proportioned such that the initial nominal compressive stresses are limited within a range of 400 psi (2.8 MPa) to 1,000 psi (7 MPa) based on the net cross section of the ring, excluding haunches or adjacent wall.

3.6.5.4 Nonprestressed reinforcing steel shall be used in the dome ring to control shrinkage and temperature effects prior to prestressing. The minimum area of circumferential steel shall be 0.0025 times the cross-sectional area of the dome ring.

3.6.5.5 When the dome ring is separated from the tank wall, as in Figure 2C, positive means, such as keyways, flexible seismic cables, or doweling, shall be provided to prevent excess lateral displacement of the dome in the event of seismic activity. Where such a detail is used, the joint shall be designed to accommodate controlled radial movement at the top of the wall during circumferential prestressing and fluctuations in water level.

3.6.5.6 All roof-wall joints shall be designed to prevent dome roof runoff from penetrating the interface between the core wall and the circumferential prestressed wall reinforcement.

Sec. 3.7 Other Roof Designs

3.7.1 *General.* Other types of roof structures constructed of concrete, steel, aluminum, and fiberglass-reinforced plastic may be used if designed in conformance with currently accepted standards. The design shall provide a weathertight roof to prevent leakage and contamination of the tank contents. Consideration shall be

Copyright by the American Water Works Association
Wed Feb 02 02:16:45 2005

AWWA D110 95 ■ 0783350 0502981 428 ■

given for severe exposure conditions and condensation on the underside of the roof. Concrete slab roofs shall be reinforced to resist temperature-gradient stresses. The design shall include crack control to prevent leakage and corrosion of the reinforcement. Nonprestressed cast-in-place or precast concrete slab roofs for potable-water tanks shall have a minimum slope of 1½ percent, or a suitable coating or membrane shall be provided to prevent liquids from leaking into the tank and contaminating the contents.

3.7.1.1 Nonprestressed steel-reinforced concrete flat slabs shall conform to the applicable requirements of ACI 350R, with special attention to crack control.

Sec. 3.8 Floor Design

The floor may be either structural or membrane type.

3.8.1 *Structural floors.* Structural floors that are properly reinforced for supporting the tank contents, for resisting maximum hydrostatic uplift forces, for locations with expansive soils, or for other unusual foundation conditions may be used where conditions warrant. Structural reinforced-concrete floors used for these purposes shall be designed in accordance with the requirements of ACI 318 and ACI 350R with special attention to crack control. Under some conditions, anchorage to underlying foundation strata or a sufficiently heavy concrete floor system can provide a satisfactory solution to hydrostatic uplift.

3.8.2 *Membrane floors.* In cast-in-place concrete membrane floors, loads are assumed to be transmitted to the subbase directly through the membrane. Minimum thickness of the membrane shall be 4 in. (100 mm). Floors shall be placed continuously in sections as large as practicable to decrease the length of construction joints and potential leakage problems related to their presence. Precautions shall be taken with large floor sections to limit long-term shrinkage by using concrete with a properly controlled water–cement ratio, adequate reinforcement, and proper curing conditions. Hydrostatic uplift when the tank is empty or when the tank water level is lowered during operation shall be precluded by adequate surface drainage, a perimeter drain around the tank wall foundation, and underdrainage, if necessary.

3.8.3 *Watertightness.* Where construction or expansion joints are provided in floors, waterstops shall be used to ensure watertightness under a head of water equal to the height of the tank (see Figure 3). In expansion joints, an acceptable joint sealant shall be used in addition to the waterstop to prevent entry of foreign material into the joint and to ensure its performance.

The slab at the joint may be thickened to allow additional space for the waterstop and reinforcement. For a restrained joint, the reinforcement shall be continuous through the joint. Additional nonprestressed reinforcement shall be provided in the thickened portion of slab plus 2 ft (0.75 m) of the subsequently placed membrane slab parallel to the construction joint to control cracking. Alternate designs with nonrestrained (unbonded) joints are acceptable provided the watertightness criteria are met.

Subgrade rigidity and uniformity shall be carefully controlled to limit differential vertical movement at joints. For crack control in the floor, the minimum reinforcement in each direction in the horizontal plane shall be 0.5 percent of the concrete area. Where the wall-base shear is transferred into radial tension in the slab, additional reinforcement shall be provided as required. Expansion joints shall not be used in floors of tanks in seismic zones 2B or higher, unless special precautions are taken to ensure adequate performance of the joint under seismic loadings.

Copyright by the American Water Works Association
Wed Feb 02 02:16:46 2005

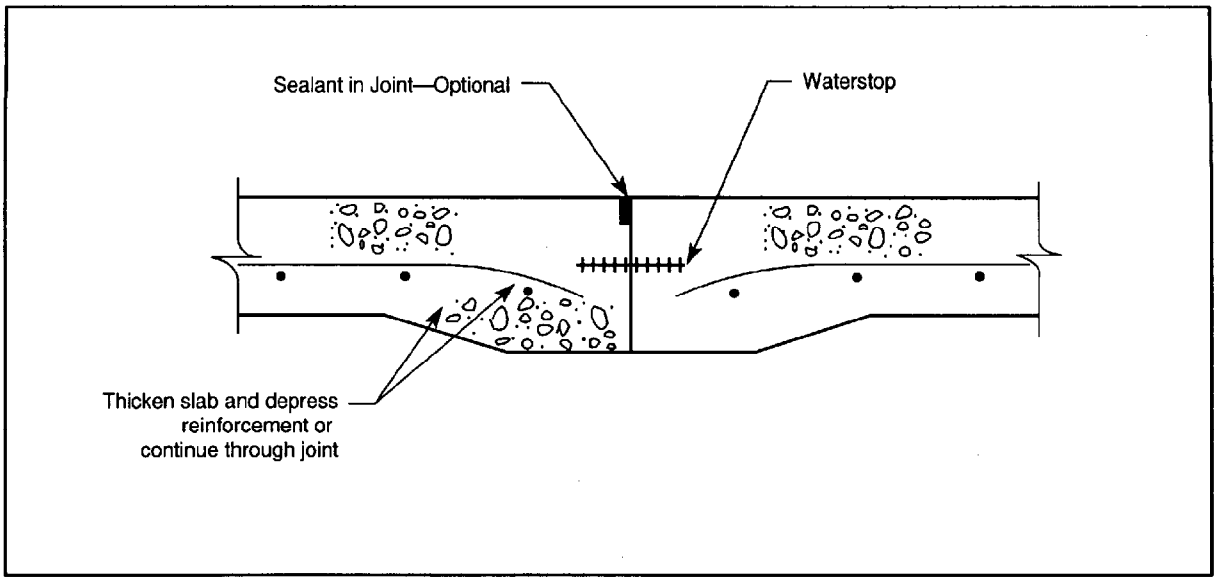

Figure 3 Typical floor-slab construction joint

3.8.4 *Subgrade.* The subgrade for membrane floors shall have adequate bearing capacity to sustain the weight of the tank, fluid contents, and roof load. The floor slab shall not be constructed directly on the natural subgrade soil or rock unless it is uniform and compact.

3.8.4.1 The subgrade for membrane floors must be of uniform density and compressibility to minimize differential settlement of the floor and footings. Disturbed subgrade or loosely consolidated soil or foundation material shall be removed and replaced with suitable compacted soil, or it shall be compacted in place. Compaction shall achieve a density of at least 95 percent of the maximum laboratory density determined by ASTM D1557. Field tests for measurement of in-place density shall be in accordance with ASTM D1556. Overexcavation and replacement with compacted imported material may be required if foundation soils are unsatisfactory for the imposed loadings or do not provide uniform support.

3.8.4.2 The subgrade for all types of floors shall be so designed that leakage through the floor will not cause erosion and settlement in excess of that provided for in the design or will not cause other types of failure.

3.8.5 *Floor base.* Use of a clean, well-compacted granular base with a minimum thickness of 6 in. (150 mm) shall be used for tanks when the natural subgrade does not meet drainage requirements or is difficult to prepare for floor construction. Gradation should be selected to permit free drainage without loss of fines. When suitable base material is not available, the use of geotextile fabrics shall be used.

3.8.5.1 Where site conditions indicate the possibility of hydrostatic uplift of the floor, a properly designed structural floor shall be used or adequate drainage of the floor base shall be provided to relieve the hydrostatic pressure and remove the water from the site. Drainage to a manhole or other drainage structure where the flow can be observed and measured is recommended. The receiving structure shall be below the level of the floor slab to guard against surcharge and backflow to the floor base.

AWWA D110 95 ■ 0783350 0502983 2T0 ■

Sec. 3.9 Footing Design

3.9.1 *Wall footings.* When separated wall–floor connections are used at the base of the wall, a continuously reinforced concrete footing, either as a thickened floor edge region, an inverted footing, or one separated from the floor, shall be provided to distribute the vertical loads at the base of the wall to the underlying foundation material. A suitable waterstop shall be provided in all such separated wall-base joint connections. Reinforced nonsliding wall-base tanks shall employ a thickened and reinforced floor edge region to distribute wall loads to the foundation. Foundation for membrane floors and footings shall be of uniform compaction and bearing value to support the structure without differential settlement that may damage the structure. Footings and integral floor slab shall be designed to resist the entire radial and tangential shears from the wall.

3.9.2 *Column footings.* Column footings shall be designed in accordance with ACI 350R and may be an integral part of the membrane floor. Separation of the column footing from the floor requires the use of submerged joints that increase the potential for leakage. Where footings are placed below the floor slab and integral with it, additional reinforcing may be required to control cracking due to restriction of slab movement during curing and temperature or moisture changes. Inverted footings above the slab avoid this condition, but may entrap sediment and impede normal washdown and cleaning maintenance. Transitions in floor thickness should be gradual and additionally reinforced for flexural stresses and control of shrinkage cracking and leakage.

Sec. 3.10 Columns

Columns shall conform to the requirements of ACI 318, including supplements thereto. Minimum concrete cover over principal reinforcement shall be 2 in. (50 mm).

Sec. 3.11 Tank Appurtenances

This section is intended only to provide guidance to the purchaser and the designer in the functional aspects of appurtenances to be considered in the tank design.

The tank appurtenances and accessories to be provided shall be in accordance with ANSI and OSHA standards and the special requirements of governing agencies responsible for health and safety in the locality where the tank is to be constructed.

3.11.1 *Inlet and outlet piping arrangement.* Disinfectant contact time and residual should be considered in the design. Baffles or directional inlets may be required to achieve water quality objectives. This is particularly important for large tanks or where the daily fluctuations in water level do not provide adequate circulation.

3.11.1.1 The inlet and outlet pipes should be controlled by valves outside the tank that can be closed for tank inspection and maintenance.

3.11.1.2 The outlet connection should allow water to flow out of the tank with minimum head loss. This is especially important when the tank is used as suction storage for a pumping station and allowable head loss is limited. The outlet connection is generally depressed below the base of the tank wall, and its entrance may be flared to reduce head loss.

Where sediment from residual turbidity may accumulate in the tank during use, a removable silt stop may be placed on the outlet to prevent its entry into the outlet pipe during periods of high draft.

Copyright by the American Water Works Association
Wed Feb 02 02:16:47 2005

3.11.1.3 Concrete encasement of all inlet–outlet piping placed under the floor slab is recommended for added corrosion protection and to ensure against leakage during the useful life of the structure. Flexible joints should be provided outside the wall footing to accommodate any movement due to differential settlement or seismic activity.

3.11.2 *Tank overflow and drain.*

3.11.2.1 The tank overflow system must normally be designed to pass the maximum filling rate. The overflow weir, flared inlet, or vortex breaker should be sized to pass the design flow at the maximum static water surface permitted in the wall and roof design. The freeboard specified in Sec. 4.10 is measured from the maximum static water surface to the underside of the roof slab or dome roof at its intersection with the inside face of the wall.

The overflow line should extend to a point outside the wall where it can freely discharge without unacceptable consequences and terminate with a screen, flap valve, or other device for preventing access by small animals into the tank through the overflow.

3.11.2.2 A washdown piping connection from the supply system with washdown piping and valved hose connection inside the tank or outside adjacent to the tank access ladder may be desirable design features for large-diameter tanks. Temporary pumping may be required for effective washdown pressure. Uniformly sloping the floor from its high point to the drain will facilitate wash down and cleaning.

3.11.2.3 A tank drain line, valved outside the tank, is normally provided to dispose of washdown water during inspection and cleaning. The drain line may be taken from the effluent line, if the effluent line starts at the low point in the tank floor.

There may be circumstances where an underdrain system is required to prevent hydrostatic uplift under the tank floor when the tank is emptied. If the tank may be subjected to hydrostatic uplift that cannot be relieved by a gravity drain system, an alarm system and/or automatic means of pumping down the water table to prevent groundwater entry into the tank on drawdown must be provided, or the tank floor designed to accommodate the uplift.

3.11.2.4 A pressure sensor may be provided and calibrated to the depth of water in the tank if remote level sensing or recording is required by the purchaser. Sampling connections of suitable size for accurately monitoring the quality of water in potable water tanks are also desirable features.

3.11.3 *Roof opening, hatches, and ventilators.*

3.11.3.1 All roof openings, including personnel and equipment hatches, sampling points, and ventilators should be constructed so as to prevent leakage into the tank and locked to resist unauthorized entry and vandalism.

All roof openings should be atop curbs at least 4 in. (100 mm) high. All covers should turn down at least 2 in. (50 mm) over the curbs. All frames and covers should be galvanized steel, fiberglass, or aluminum at least $3/16$ in. (5 mm) thick. Personnel hatches shall be at least $2\frac{1}{2}$ ft (0.76 m) square and provided with protective handrails conforming to OSHA specifications, if required.

3.11.3.2 Roof ventilators should be provided to admit air at a flow rate equal to the maximum tank outflow rate at pressure differentials not exceeding 2.0 in. (50 mm) of water column (equivalent to a 10 lb/ft^2 [4.79 kPa] loading on the roof or dome). The exhaust capacity of the ventilator must be at least equal to the design fill rate of the tank.

Ventilator screens should be protected from vandalism, but must be accessible for inspection and cleaning to remove insects or airborne lint, pollen, or dust.

AWWA D110 95 ■ 0783350 0502985 073 ■

3.11.4 *Ladders and stairs.* All access ladders shall conform to OSHA requirements. Galvanized or painted steel may be suitable for outside ladder construction, but more corrosion-resistant structural materials, such as aluminum, stainless steel, and fiberglass-reinforced plastic, are recommended for interior ladder construction. Flat steel bar stock, steel pipe, and aluminum tubing have been commonly used for ladder stringers. Normal rung spacing is 12 in. (300 mm), and distance from the floor or landing to the bottom rung of inside ladders should be the same as the rung spacing.

Flat bar ladder stringers should be punched to receive rungs. Rungs and brackets should be welded to stringers. Stringers should be at least ⅜ by 2½ in. (10 by 63 mm), and rungs should be at least 1 in. (25 mm) in diameter. Brackets may be made of the same bar size as the stringers. Ends of ladder stringers should be rounded.

Outside ladders should be provided with hinged plate covers or other devices, extending far enough above ground to discourage unauthorized climbers. The cover or other device would be unlocked and swung aside for entry by authorized personnel.

Outside stairs should be fitted with handrails and landings at intervals specified by OSHA.

3.11.5 *Wall manholes.* When wall manholes in prestressed concrete tank walls are specified, the transfer or prestress forces around the wall opening may be handled by the use of stress plates or the banding of the circumferential prestressed reinforcement above and below the opening. Special consideration must be given to localized wall stresses, the spacing and protection of the prestressed reinforcement, and waterstop integrity.

3.11.6 *Architectural treatments.* Special architectural treatments are frequently used to enhance the appearance of prestressed tanks, including pilasters, brick, or precast facing panels and special finishes applied over the shotcrete cover coat. Care must be exercised in the selection and installation of anchorages and attachments for pilasters and wall facings to isolate them from contact with the prestressed reinforcement and eliminate the potential for corrosion of the reinforcement.

SECTION 4: PROVISIONS FOR EARTHQUAKE-INDUCED FORCES

Sec. 4.1 Introduction

4.1.1 *Design method.* The seismic design procedure for wire- or strand-wound, circular, prestressed concrete tanks may be the effective-mass method or a more accurate analysis method for seismic design (see appendix A). The effective-mass method recognizes the reduction in seismic load due to the sloshing of the contained liquid. The procedure outlined in Sec. 4.3 is based on this method. No seismic design is required for tanks located in seismic zone classification 0.

The user of this standard is directed to appendix A for references providing background on the theory of plates and shells and for other general reference material commonly used in the design of liquid containment structures subjected to earthquake-induced forces.

4.1.2 *Notation.* Symbols used in the various equations presented in Sec. 4 are defined as follows:

A = area of cable or strand, in in.^{2} (mm^2)

Copyright by the American Water Works Association
Wed Feb 02 02:16:48 2005

A_I = the peak amplified acceleration consistent with the impulsive period at 5.0 percent damping, in units of gravitational acceleration (g); see definition for g below and Sec. 4.3.2

B = fraction of site horizontal acceleration to be used in vertical acceleration calculation, see Sec 4.5.1

C_C = convective coefficient, see Sec. 4.3.1(6)

C_I = impulsive coefficient, see Sec. 4.3.1(3)

C_V = coefficient of vertical acceleration, see Sec.4.5.1

d = slosh height, in ft (m); see Sec. 4.10

D = inside tank diameter, in ft (m)

D_c = the spectral displacement consistent with the convective period at 0.5 percent damping, in ft (m); see Sec. 4.3.2

E = modulus of elasticity of cable or strand, in lb/in./in. (grams/mm/mm)

E_c = modulus of elasticity of concrete, in lb/in./in. (grams/mm/mm)

G = shear modulus of elastomeric pad, in lb/in./in. (grams/mm/mm)

g = acceleration due to gravity, 32.2 ft/s^2 (9.80665 m/s^2)

H = maximum depth of water acting on the tank shell, in ft (m)

H_t = distance from the center of gravity of roof to the tank floor, in ft (m)

I = importance factor from Table 3

K_p = the factor from Figure 6 for the ratio of inside tank radius, in ft (m), to maximum depth of water, r/H, in ft (m)

k = spring stiffness per unit length of circumference for cable or elastomeric pad, or both, in lb/ft/ft (grams/m/m); see Sec. 4.3.1(5)

L_c = length of cable assumed to stretch, taken as sleeve length plus 35 times strand diameter, in in. (mm)

L_p = length of bearing pad along circumference, in in. (mm); see Sec. 4.3.1(5)

M_C = overturning moment applied to the bottom of tank shell due to convective forces, in lbf• ft (N• m); see Sec. 4.3.1(2)

M_I = overturning moment applied to the bottom of tank shell due to impulsive forces, in lbf• ft (N• m); see Sec. 4.3.1(2)

M_T = total overturning moment applied to the bottom of tank shell, in lbf• ft (N• m); see Sec. 4.3.1(2)

N_C = equivalent axisymmetric convective circumferential hoop load, in lb (kg); see Sec. 4.5.3

N_I = equivalent axisymmetric impulsive circumferential hoop load, in lb (kg); see Sec 4.5.3

N_T = total equivalent axisymmetric circumferential hoop load, in lb (kg); see Sec 4.5.3

N_V = hoop load due to vertical acceleration, in lb (kg); see Sec. 4.5.3

P_c = maximum vertical shell compressive force, in lbf/ft (kg/m) of shell circumference; see Sec. 4.4.5

P_t = maximum vertical shell tensile force or the minimum vertical shell compressive force, in lb/ft (kg/mm) of shell circumference; see Sec. 4.4.6

r = inside radius of tank wall, in ft (m)

R_I = impulsive structure coefficient, from Table 4

R_C = convective structure coefficient, from Table 4

R_V = structure coefficient for vertical acceleration, see Sec. 4.5.1

S = soil profile coefficient (site amplification factor) from Table 5

S_c = spacing between the cable sets, in in. (mm)

S_p = spacing of elastomeric pads, in in. (mm); see Sec. 4.3.1(5)

Copyright by the American Water Works Association
Wed Feb 02 02:16:48 2005

T_I = natural period of tank and impulsive contents, in seconds; see Sec. 4.3.1(4)
T_c = the first-mode sloshing wave period, in seconds; see Sec. 4.3.1(6)
t = thickness of elastomeric pad after precompression due to dead load, in in. (mm)
t_b = tank core wall thickness at the base, in in. (mm)
$\ddot{u}_V$ = vertical acceleration, in ft/s^2 (m/s^2); see Sec. 4.5.1
V_C = base shear at the bottom of the tank shell due to convective force, in lb (kg); see Sec. 4.3.1(1)
V_I = base shear at the bottom of the tank shell due to impulsive forces, in lb (kg); see Sec. 4.3.1(1)
V_T = total base shear at the bottom of the tank shell, in lb (kg)
W_C = weight of effective mass of the first-mode sloshing contents of the tank, in lb (kg); see Sec. 4.3.1(7)
W_I = weight of effective mass of tank contents that moves in unison with the tank shell, in lb (kg); see Sec. 4.3.1(7)
W_R = total weight of the tank roof, plus a portion of snow or other roof live load, in lb (kg)
W_S = total weight of the tank wall (shell), in lb (kg)
W_T = the total weight of tank contents, in lb (kg); see Sec. 4.3.1(7)
w = width of elastomeric bearing pad in radial direction, in in. (mm)
w_t = weight of the tank, in lb/ft (kg/m) of shell circumference; see Sec. 4.4.5
X_C = height from the bottom of the tank shell to the centroid of W_C, in ft (m); see Sec. 4.3.1(8)
X_I = height from the bottom of the tank shell to the centroid of W_I, in ft (m); see Sec 4.3.1(8)
X_S = height from bottom of tank shell to center of gravity of the shell, in ft (m); see Sec. 4.3.1(2)
Z = zone coefficient from Table 2
α = angle of cable or strand with horizontal, in degrees
γ = unit weight of water, 62.4 lb/ft^3 (999.55 kg/m^3)
μ = coefficient of friction, see Sec. 4.7.1

Sec. 4.2 Seismic Design Categories

4.2.1 *Wall-base joint types.* For purposes of seismic design, externally wrapped, prestressed, concrete water-storage tanks currently in use can be classified into tanks with the following three types of joints between the wall and the foundation:

1. Reinforced nonsliding base. Tanks with a substantially fixed joint between the wall and the foundation (Figure 4A) that are tied to the footing and floor by adequate steel reinforcement.

2. Anchored flexible base. Tanks with an anchored flexible joint between the wall and the foundation. Anchorage is achieved by diagonal strand seismic cables embedded in the wall and in the footing, as shown in Figure 4B, which resist tangential movements but permit only limited radial movements of the wall.

3. Unanchored and uncontained flexible base. Tanks with an unanchored and uncontained flexible joint between the wall and the foundation; flexibility is achieved by an elastomeric bearing pad (Figure 4C).

Table 2 Zone coefficient

Seismic Zone Classification*	Zone Coefficient Z
1	0.075
2A	0.15
2B	0.20
3	0.30
4	0.40

*The Uniform Building Code (UBC) assigns seismic zone classifications for areas both outside and within the United States as illustrated by the seismic zone map of Figure 5. These classifications are periodically updated based on data from site-specific seismic events. Many state and local building codes have also adopted governing seismic zone classifications more stringent than those designated by the UBC.

For determination of the seismic zone classification for the project location, the user of this standard should refer to the latest revision of the UBC or to equivalent local building codes for the design peak ground acceleration.

The unanchored and uncontained flexible base joint of Figure 4C has generally proved adequate for use in seismic zones 2A and below, although it is recommended that adequacy should be investigated for questionable site-specific conditions or importance factors greater than 1.0 (see Tables 2 and 3).

Table 3 Importance factor

Tank Use	Importance Factor I
Tanks that must remain usable to provide emergency service, with slight structural damage and insignificant leakage after an earthquake	1.25
Tanks that must remain usable, but may suffer repairable structural damage, and can be taken out of service, inspected, and repaired at some convenient time after an earthquake	1.0

Table 4 Structure coefficient for type of tank

Structure	Structure Coefficient	
	R_I	R_C
Tanks with a reinforced nonsliding base (Fig. 4A)	2.75	1.0
Tanks with an anchored flexible base (Fig. 4B)	4.5	1.0
Tanks with an unanchored and uncontained flexible base (Fig. 4C)	2.0	1.0

Tanks with hinged bases or unanchored and containing flexible bases, while used in the past, are no longer used in current practice in wire- and strand-wound tank construction.

4.2.2 *Applicability of base joint types.* Tanks to be located in seismic zones 2B, 3, and 4 (see Table 2 and associated footnote) shall use a Sec. 4.2.1, Figure 4A or Figure 4B type joint that anchors the wall to the foundation to prevent or restrict wall displacement during a seismic event. The fixed base joint described in Sec. 4.2.1(1), Figure 4A, has been used in seismic zones 3 and 4 primarily in tanks of 2.0 mil gal (7.57 ML) capacity or smaller, whereas the radially freed but anchored flexible base joint described in Sec. 4.2.1(2), Figure 4B, has been used in tanks of all sizes. The fixed base is not recommended for larger tanks in seismic zones 3 and 4 without

Table 5 Soil profile coefficient

Soil Profile Coefficient*	Soil Profile Type			
	A	*B*	*C*	*D*
S	1.0	1.2	1.5	2.0

*The following is an explanation for the determination of the soil profile coefficient. The soil profile coefficient shall be specified by the purchaser. Site effects on tank response shall be established based on the following soil profile factors:

1. *Soil profile type A* is a profile with
   a. A rock-like material characterized by a shear wave velocity greater than 2,500 ft/s (764 m/s) or by other suitable means of classification.
   b. Stiff or dense soil condition where the soil depth is less than 200 ft (61 m).
2. *Soil profile type B* is a soil profile with dense or stiff soil conditions where the soil depth exceeds 200 ft (61 m).
3. *Soil profile type C* is a soil profile 70 ft (21 m) or more in depth and containing more than 20 ft (6 m) of soft to medium-stiff clay but not more than 40 ft (12 m) of soft clay.
4. *Soil profile type D* is a soil profile containing more than 40 ft (12 m) of soft clay characterized by a shear wave velocity less than 500 ft/s (153 m/s).
5. For tanks in seismic zones 3 and 4 and for tanks having an importance factor greater than unity, the soil profile shall be determined by a geotechnical investigation. In other locations, where the soil profile is not known in sufficient detail to determine the soil profile type, soil profile C may be assumed. Soil profile type D need not be assumed unless there is reasonable evidence that it exists, or its presence is established by geotechnical data.

full consideration and adequate reinforcement to counteract the base shear and vertical bending moments induced in the wall and its interaction with the footing and floor slab.

4.2.3 *Wall-to-roof joint connection.* Any of the above categories of tanks may have, at the wall-to-roof connection, a joint that is substantially fixed, has flexible or rigid ties, or that has no ties (elastomeric pad only). A joint with an elastomeric pad and without ties shall be contained to preclude excessive lateral displacement between the roof and the wall. The tank design shall have provisions that prevent the upward displacement of the roof with respect to the wall due to the height of the sloshing wave and vertical accelerations (see Sec. 4.10).

The designer should also consider increasing the zone coefficient in the vicinity of known faults where peak ground accelerations have been observed or may be anticipated in excess of those that have a 10 percent chance of exceedance in 50 years (see Sec. 4.3.2).

Sec. 4.3 Seismic Design Loads

4.3.1 *Effective-mass procedure for determining base shear and overturning moment due to seismic effects.* The effective-mass procedure considers the following two response modes of the tank and its contents: (1) the impulsive mode, which is the high-frequency amplified response to lateral ground motion of the tank shell and roof together with that portion of the liquid contents that moves in unison with the shell, and (2) the convective mode, which is the low-frequency amplified response of a portion of the liquid contents in the fundamental sloshing mode. The design requires the determination of the hydrodynamic mass associated with each mode and the lateral force and overturning moment applied to the shell resulting from the response of the masses to lateral ground motion. Because the two different response modes are not maximized at the same time, the root mean square can be used for combining forces and moments resulting from the two response modes.

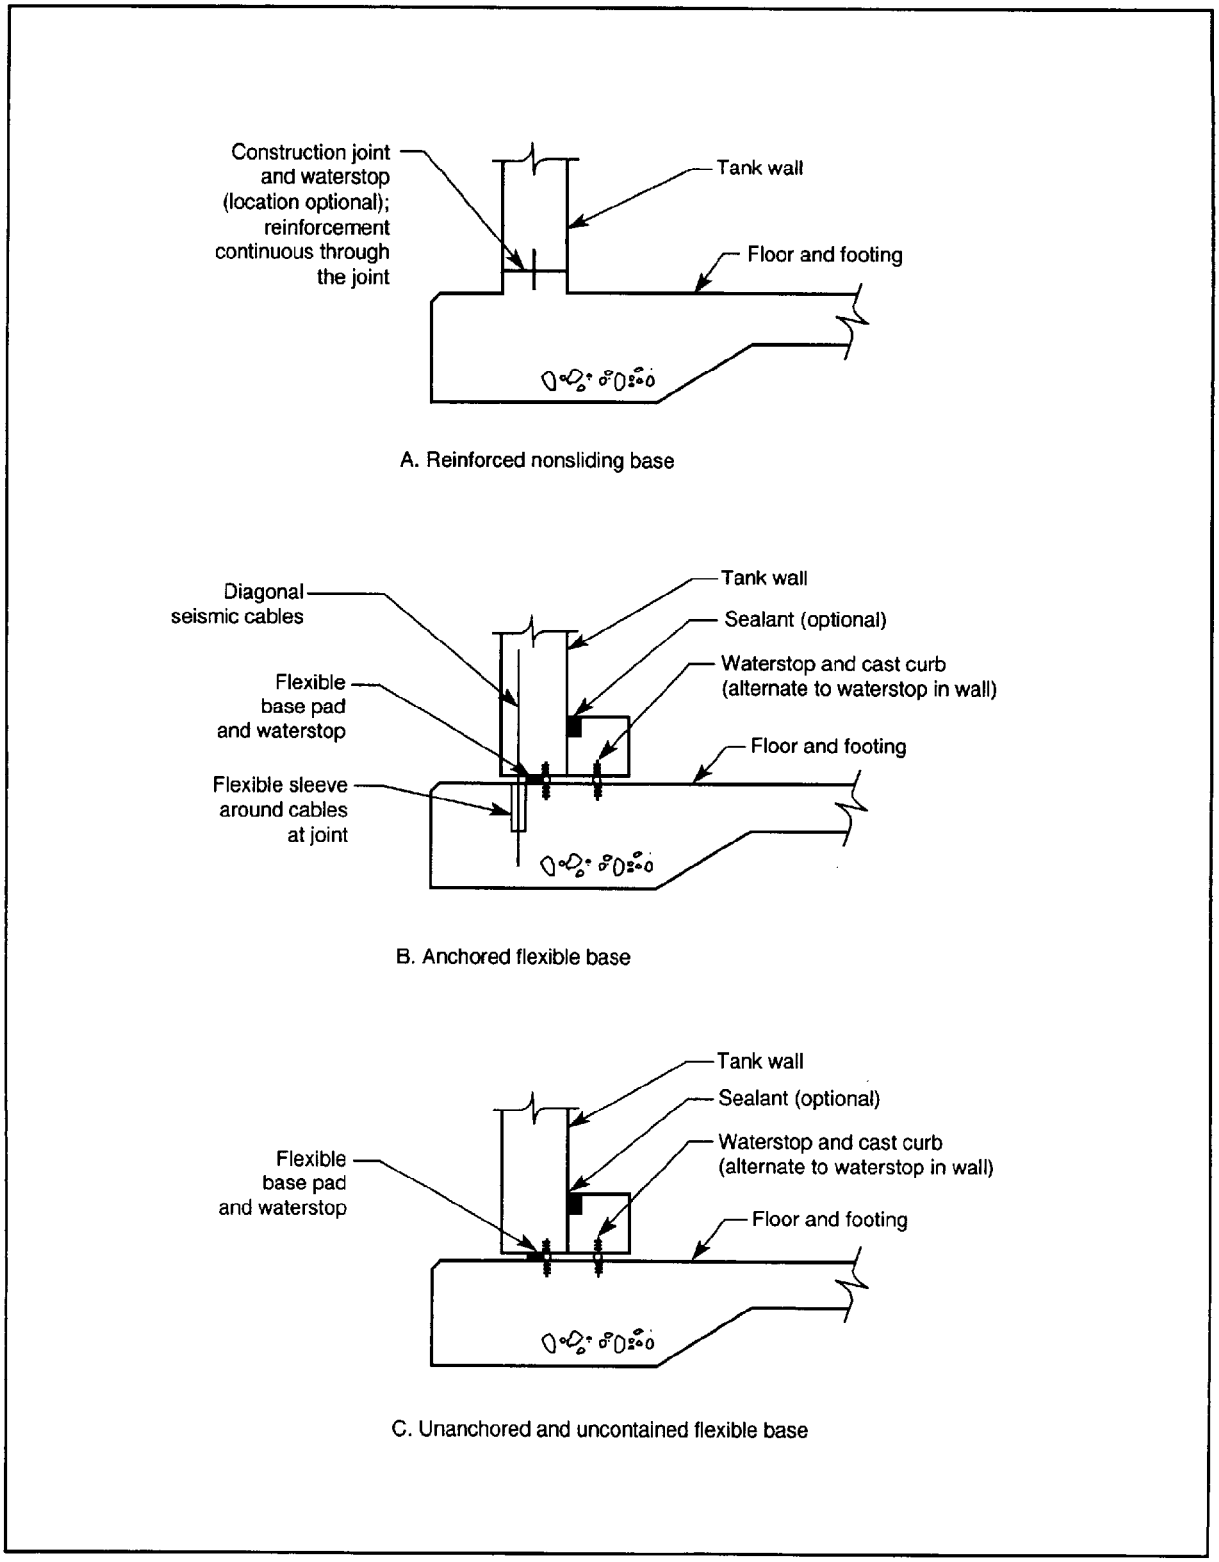

Figure 4 Types of joints used between the wall and its foundation

Copyright by the American Water Works Association
Wed Feb 02 02:16:49 2005

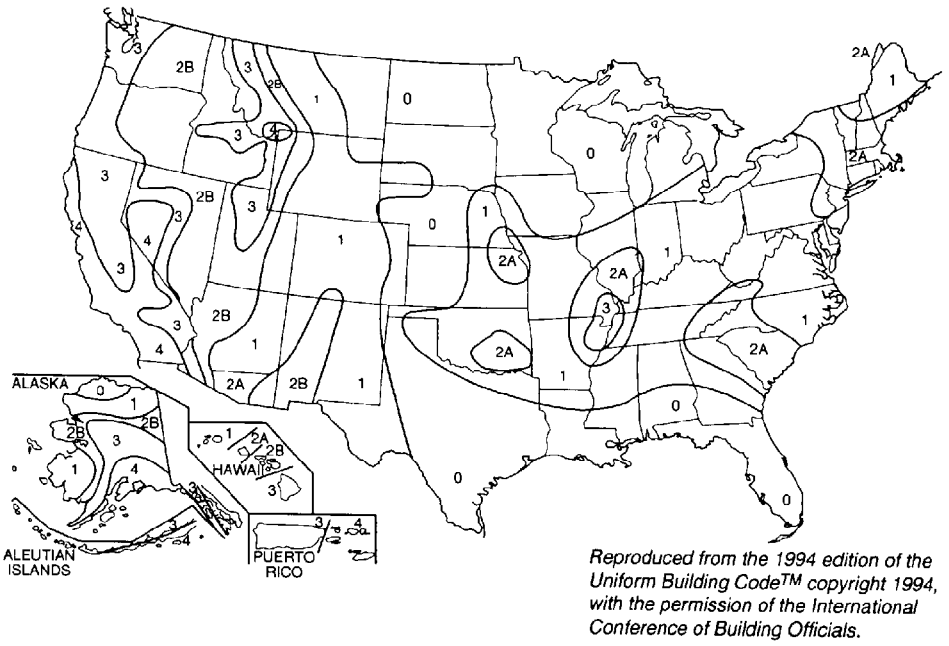

Figure 5 Seismic zone map of the United States (see notes accompanying Table 2)

1. The lateral or horizontal base shear due to seismic forces applied at the bottom of the tank wall shall be determined by Eq 4-1, 4-2, and 4-3. Refer to Sec. 4.1.2 for definition of symbols.

$$V_I = \frac{ZIC_I}{R_I}(W_S + W_R + W_I) \qquad \text{(Eq 4-1)}$$

$$V_C = \frac{ZIC_C}{R_C} W_C \qquad \text{(Eq 4-2)}$$

$$V_T = \sqrt{V_I{}^2 + V_C{}^2} \qquad \text{(Eq 4-3)}$$

In the case of Figures 4A and 4B bases, the wall design shall provide for 100 percent of the base shear V_T to be transferred tangentially. In addition to providing for 100 percent of the base shear to be transferred tangentially as noted above, for Figure 4A bases, the maximum radial base shear at 0° from the direction of the earthquake, along with the corresponding vertical bending moments and hoop forces, shall also be provided for in accordance with Sec. 4.5.3.

In the case of Figure 4B bases with diagonal seismic cables between the footing and the wall, the wall design shall provide for 100 percent of the base shear to be transferred tangentially. In addition, for Figure 4B bases, the maximum hoop forces at 0° from the direction of the earthquake shall also be provided for in accordance with Sec. 4.5.3.

Copyright by the American Water Works Association
Wed Feb 02 02:16:50 2005

2. The overturning moment due to seismic forces applied at the bottom of the tank wall shall be determined by Eq 4-4, 4-5, and 4-6. Refer to Sec. 4.1.2 for definition of symbols.

$$M_I = \frac{ZIC_I}{R_I}(W_S X_S + W_R H_t + W_I X_I) \quad \text{(Eq 4-4)}$$

$$M_C = \frac{ZIC_C}{R_C} W_C X_C \quad \text{(Eq 4-5)}$$

$$M_T = \sqrt{M_I{}^2 + M_C{}^2} \quad \text{(Eq 4-6)}$$

3. The impulsive coefficient C_I is determined from Eq 4-7. However, C_I need not exceed 2.75.

$$C_I = \frac{1.25S}{T_I^{2/3}} \quad \text{(Eq 4-7)}$$

4. The tank's natural period T_I may be determined by a rational analysis that considers the weight of the tank wall and roof and effective weight W_I of the tank contents. For calculating the impulsive coefficient C_I, it shall be assumed that the period of the tank and its impulsive contents is 0.3 s or less for tanks with a reinforced nonsliding base (Figure 4A) unless substantiated to be longer. For tanks with anchored flexible bases (Figure 4B) and tanks with unanchored and uncontained flexible bases (Figure 4C), T_I may be determined from Eq 4-8. However, T_I shall not exceed 1.0 s for Figure 4B tanks, nor 2.0 s for Figure 4C tanks. Refer to Sec. 4.1.2 for definition of symbols.

$$T_I = \sqrt{\frac{4\pi (W_S + W_R + W_I)}{g\, r\, k}} \quad \text{(Eq 4-8)}$$

5. For tanks with a Figure 4B, base-joint type, the spring stiffness k is determined from Eq 4-9. Refer to Sec. 4.1.2 for definition of symbols. In Eq 4-9 and 4-10, for a tank with a continuous bearing pad, the ratio L_p/S_p= 1.0. For a tank with a series of bearing pads, for example, having lengths of 6 in. (150 mm) spaced at 12 in. (300 mm) on centers, L_p/S_p = 0.5.

$$k = 144\left[\frac{(AE)\cos^2\alpha}{L_c S_c} + \frac{2G\, w\, L_p}{tS_p}\right] \quad \text{(Eq 4-9)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:16:50 2005

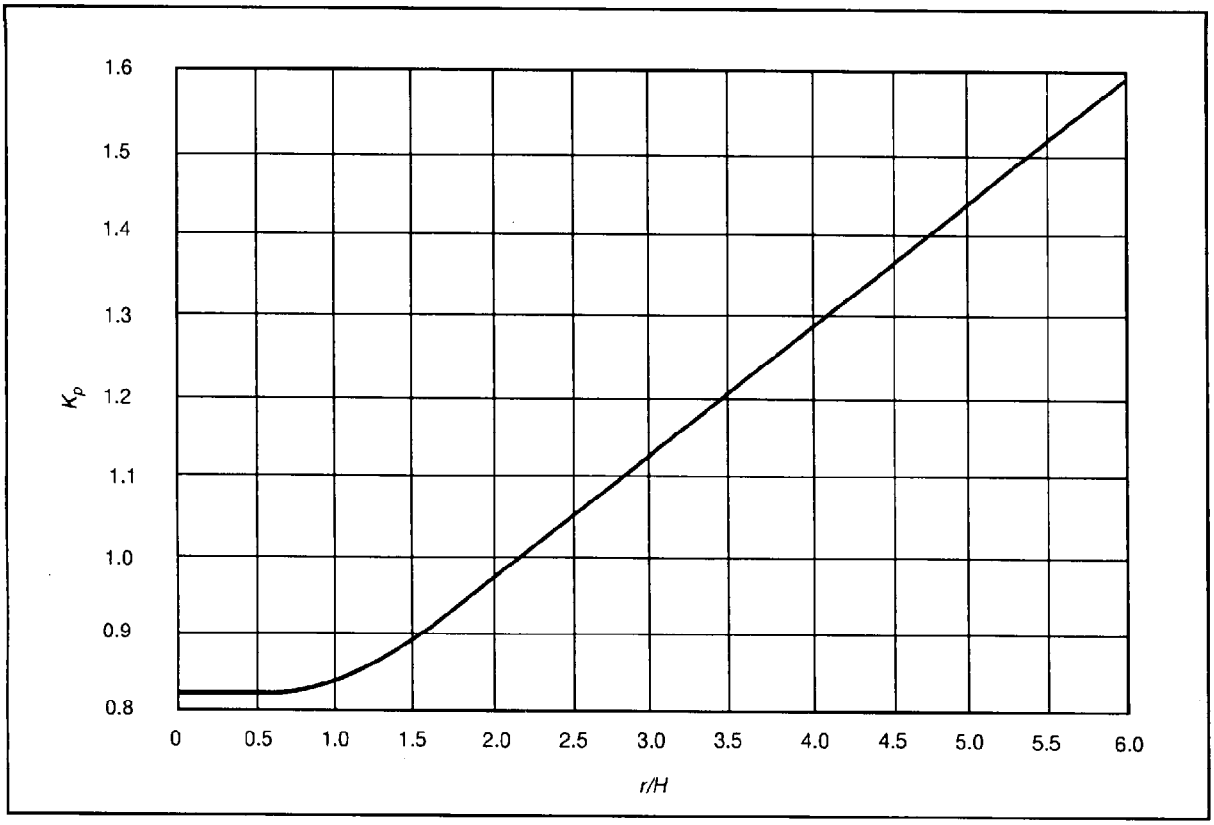

Figure 6 Curve for obtaining factor K_p for the ratio r/H

For tanks with Figure 4C base-joint type, k is determined from Eq 4-10.

$$k = \left[144 \frac{2G\,w\,L_p}{tS_p}\right] \qquad \text{(Eq 4-10)}$$

NOTE: Eq 4-9 and 4-10 were derived without including the effects of the flexibility of the tank shell and the wall-to-roof connection. These effects may be important under some circumstances.

6. The convective coefficient C_C is determined from Eq 4-11. Refer to Sec. 4.1.2 for definition of symbols.

$$C_C = \frac{4S}{T_c{}^2} \qquad \text{(Eq 4-11)}$$

The first-mode sloshing wave period T_c is determined from Eq 4-12 and K_p is obtained from Figure 6.

$$T_c = K_p \sqrt{r} \qquad \text{(Eq 4-12)}$$

or

$$T_c = \sqrt{\frac{r}{1.5 \tanh\left(\sqrt{3.375}\, H/r\right)}}$$

Copyright by the American Water Works Association
Wed Feb 02 02:16:50 2005

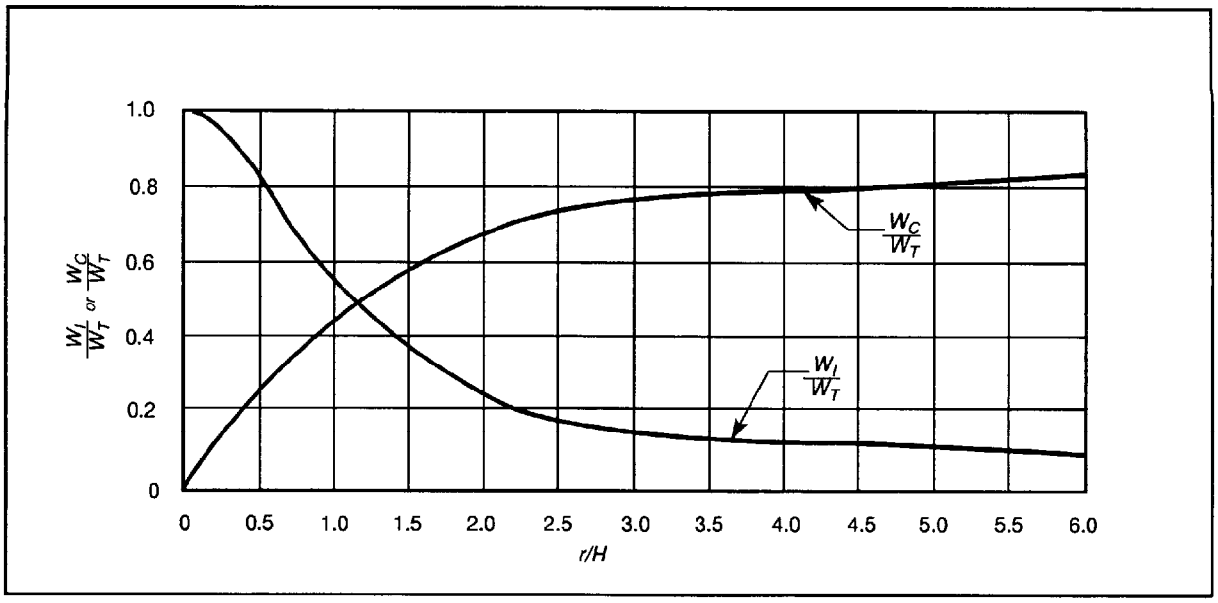

Figure 7 Curves for obtaining factors W_I/W_T and W_C/W_T for the ratio r/H

7. Effective mass of tank contents. The weight of the impulsive mass of the tank contents that moves in unison with the tank shell W_I and the weight of the convective mass of the first-mode sloshing contents W_C may be determined by multiplying W_T by the ratio W_I/W_T and W_C/W_T, respectively, obtained from Figure 7 for the ratio r/H of the tank, or from Eq 4-14 and 4-15.

The total weight of the tank contents W_T is determined from Eq 4-13. Refer to Sec. 4.1.2 for definition of symbols.

$$W_T = \gamma \pi r^2 H \qquad \text{(Eq 4-13)}$$

$$\frac{W_I}{W_T} = \frac{\tanh (\sqrt{3}\ r/H)}{(\sqrt{3}\ r/H)} \qquad \text{(Eq 4-14)}$$

$$\frac{W_C}{W_T} = \frac{\sqrt{3.375}\ r \tanh \sqrt{3.375}\ H/r}{4H} \qquad \text{(Eq 4-15)}$$

8. The heights X_I and X_C from the bottom of the tank shell to the centroids of the lateral seismic forces applied to W_I and W_C may be determined by multiplying H by the ratios X_I/H and X_C/H, respectively, obtained from Figure 8 for the ratio r/H or from Eq 4-16 and 4-17.

When $r/H \leq 0.6667$, then

$$\frac{X_I}{H} = [\,0.50 - 0.1875\ (r/H)\,] \qquad \text{(Eq 4-16)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:16:51 2005

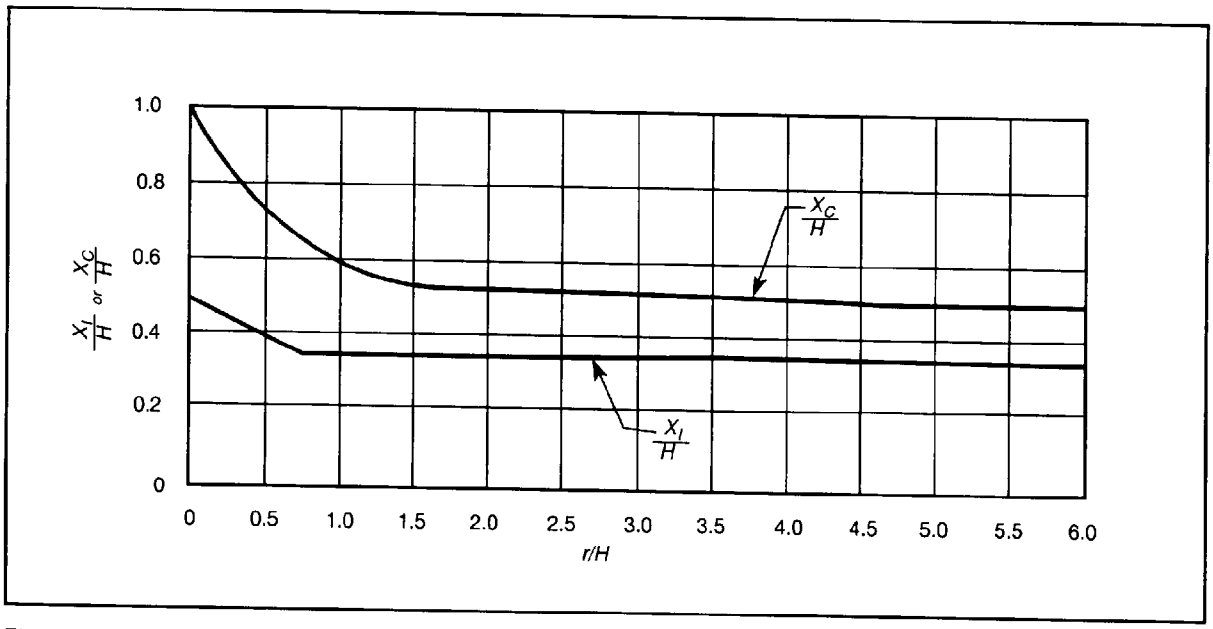

Figure 8 Curves for obtaining factors X_I/H *and* X_C/H for the ratio r/H

When $r/H >= 0.6667$, then

$$\frac{X_I}{H} = 0.375$$

For all values of r/H,

$$\frac{X_C}{H} = 1 - \left[\frac{\cosh \sqrt{3.375}\, H/r - 1}{(\sqrt{3.375}\, H/r) \sinh (\sqrt{3.375}\, H/r)}\right] \qquad \text{(Eq 4-17)}$$

9. The curves in Figure 7 and Figure 8 are based on equations in Chapter 6 and Appendix F of *Nuclear Reactors and Earthquakes* (see US Nuclear Regulatory Commission [1963] in appendix A). Alternately, W_I, W_C, X_I, and X_C may be determined by other analytical procedures based on the dynamic characteristics of the tank.

4.3.2 *Application of site response spectrum.* Where site-specific response spectra are used, the accelerations of the two masses shall replace the seismic coefficient as follows:

A_I replaces ZIC_I (in units of gravitational acceleration [g]) in Eq 4-1, 4-4, and 4-24, and $\sqrt{3.375}\, \frac{D_c}{r} \tanh (\sqrt{3.375}\, H/r)$ replaces ZIC_c (in g) in Eq 4-2, 4-5, 4-25, 4-28, and 4-29.

Refer to Sec. 4.1.2 for definition of symbols.

For tanks with a Figure 4A base joint, the natural period T_I shall be taken as the period in the range of 0.0 to 0.3 s that gives the largest base shear, unless a more precise determination of period is performed.

Copyright by the American Water Works Association
Wed Feb 02 02:16:51 2005

The zone coefficients Z represent, within the accuracy that can be expected with such a system, the peak ground accelerations that have a 10 percent chance of exceedance in 50 years. When multiplied by an importance factor I of 1.25, the probability of exceedance drops to 5 percent. Similar probabilities should be used for site-specific response spectra. The results obtained by using site-specific response spectra shall not be less than those determined by the zone-based Eq 4-1, 4-2, 4-4, 4-5, 4-24, 4-28, and 4-29.

Sec. 4.4 Vertical and Horizontal Forces

4.4.1 *Application at joints.* Wall-roof joints and wall-floor joints shall be designed to resist the horizontal and vertical forces they transmit due to the earthquake and gravity loads acting simultaneously.

4.4.2 *Effects on tank components.* Roofs, walls, and floors shall be investigated for strength and stability under tensile and compressive hoop forces, vertical bending moments, radial and/or tangential shear forces, and overturning moment resulting from earthquake-induced impulsive and convective forces and from gravity loads acting simultaneously. The impulsive and convective forces shall be converted to their maximum pressure and then this maximum pressure shall be used to analyze the wall as though it were axisymmetric for purposes of finding the maximum hoop forces, radial shears (Figure 4A tanks), and vertical bending moments (see Sec. 4.5.3).

4.4.3 *Seismic cables.* For tanks with Figure 4B bases, the strength of seismic cables and their anchorage in the tank wall and foundation shall also be investigated under tensile forces resulting from earthquake-induced base shear and overturning moment.

4.4.4 *Base-pad design considerations.* For tanks with Figures 4B and 4C bases, the strength of base pads shall also be investigated under shear and compressive forces resulting from earthquake-induced base shear, overturning moment, and gravity loads acting simultaneously. The base pads for tanks with Figure 4C bases shall be designed to resist the total earthquake-design base shear. Maximum total base-pad frictional resistance shall not exceed $\mu\ (W_S + W_R)$, where μ is the coefficient of friction, unless adequate shear keys or other positive mechanical means of attachment are provided to transfer the shear forces from the concrete to the base pads. However, such frictional resistance can be considered only if vertical accelerations have also been calculated and the gravity dead loads reduced by the effects of the vertical accelerations.

4.4.5 *Vertical forces at wall base.* The maximum vertical compressive and tensile forces, P_c and P_t, respectively, at the bottom of the tank wall due to gravity load and earthquake-induced overturning moment shall be determined from Eq 4-18 and 4-19. Refer to Sec. 4.1.2 for definition of symbols.

$$P_c = w_t \left[1 + 1.273 \frac{M_T}{D^2 w_t} \right] \qquad \text{(Eq 4-18)}$$

$$P_t = w_t \left[1 - 1.273 \frac{M_T}{D^2 w_t} \right] \qquad \text{(Eq 4-19)}$$

The weight of the tank w_t, in pounds per foot of shell circumference, shall be determined from Eq 4-20.

Copyright by the American Water Works Association
Wed Feb 02 02:16:51 2005

$$w_t = \frac{W_s + W_R}{\pi D} \qquad \text{(Eq 4-20)}$$

4.4.6 *Cable anchorage force.* The maximum vertical compressive force at the bottom of the tank wall due to gravity load and earthquake-induced base shear in tanks with Figure 4B bases shall include the vertical component of force in the anchor cables.

Sec. 4.5 Other Effects

4.5.1 *Vertical acceleration.* The tank shall be designed for vertical acceleration. Unless the use of a greater vertical acceleration is specified or agreed on by the purchaser, the vertical acceleration $\ddot{u}_V$ shall be determined from Eq 4-21. In seismic zones 3 and 4, $\ddot{u}_V$ shall be no less than one half of the horizontal acceleration.

$$\ddot{u}_V = \frac{ZIC_V}{R_V} B \qquad \text{(Eq 4-21)}$$

The value of B shall be 0.25 for seismic zones 1, 2A, and 2B; 0.50 for zone 3; and 0.60 for zone 4. The value of R_V (the structure coefficient for vertical acceleration) shall be 3.0 and C_V (the coefficient of vertical acceleration) is determined from Eq 4-22. C_V, however, need not exceed 2.75.

$$C_V = \frac{1.25S}{T_V^{2/3}} \qquad \text{(Eq 4-22)}$$

The natural period of the tank T_V may be determined from Eq 4-23.

$$T_V = 2\pi\sqrt{\frac{\gamma DH^2}{24\, g t_b E_c}} \qquad \text{(Eq 4-23)}$$

4.5.2 *Combining acceleration effects.* The strength and stability of walls, floors, and roofs shall be adequate to withstand the effects of both the design horizontal acceleration and the design vertical acceleration. Effects of maximum horizontal and vertical acceleration shall be combined by the root-sum-square method.

4.5.3 *Equivalent axisymmetric hoop loads.* Hydrodynamic seismic membrane hoop tensile stresses in the circumferential direction; radial shear; and vertical bending moments shall be determined by applying the equivalent axisymmetric hoop loads due to the response of the mass of the tank roof and shell (wall) combined with the equivalent axisymmetric hoop load due to the response of the mass of the tank contents given by Eq 4-24, 4-25, 4-26, and 4-27. The maximum radial force, summed over the full height of the tank wall (see the last two paragraphs in this section for the vertical distribution of these forces) for each component, may be obtained by dividing the following equivalent axisymmetrical hoop loads by the radius.

$$N_I = \frac{ZIC_I}{R_I} (W_S + W_R + W_I) \left(\frac{1}{\pi}\right) \qquad \text{(Eq 4-24)}$$

Copyright by the American Water Works Association
Wed Feb 02 02:16:51 2005

$$N_C = \frac{Z I C_C}{R_C} (W_C) \left(\frac{8}{9\pi}\right) \quad \text{(Eq 4-25)}$$

$$N_V = \frac{\ddot{u}_V \gamma H^2 R}{2} \quad \text{(Eq 4-26)}$$

$$N_T = \sqrt{N_I{}^2 + N_C{}^2 + N_V{}^2} \quad \text{(Eq 4-27)}$$

The vertical distribution of the impulsive hoop loads, resulting from the response of the tank contents, shall be Housner's impulsive pressure distribution (Housner 1954), or a trapezoid that approximates this distribution, increasing linearly from top to bottom. The centroid of the impulsive hoop-load distribution shall be located at a height from the bottom of the tank shell equal to the centroid X_I of the impulsive portion W_I of the tank contents. The impulsive hoop loads shall not be distributed over a height greater than the depth of the water H.

The vertical distribution of the convective hoop loads, due to the response of the tank contents, shall be Housner's convective pressure distribution (Housner 1954), or a trapezoid that approximates this distribution, decreasing linearly from top to bottom. The centroid of the convective hoop-load distribution shall be located at a height from the bottom of the tank shell equal to the centroid X_C of the convective portion W_C of the tank contents. The convective hoop loads shall not be distributed over a height greater than the depth of water H.

The vertical distribution of the vertical-acceleration hoop loads shall be a triangular distribution with the maximum at the bottom. The vertical-acceleration loads shall not be distributed over a height greater than the depth of the water H.

For purposes of calculating the combined effects on the tank wall and other components, the impulsive, convective, and vertical-acceleration loads shall be combined by taking the square root of the sum of the squares of the three components. When determining the required area of circumferential prestressed reinforcement for a given increment of wall height, the square root of the sum of the squares of the three seismic components taken at the midheight of the increment shall be added to the hydrostatic load at the midheight of the increment and divided by the allowable stress under seismic loading.

Sec. 4.6 Maximum Allowable Stresses and Reinforcement Requirements

4.6.1 *Maximum combined stresses.* Except as provided in Sec. 4.6.5, forces or stresses in the tank caused by the seismic loads given in this section, combined with all other loads that can act simultaneously, shall not exceed 1.25 times the allowable stresses given in Sec. 3.4.

4.6.2 *Reinforcement for flexural tension.* Whenever seismic effects, combined with other load effects that can act simultaneously, induce flexural tension stresses in the tank wall, bonded nonprestressed vertical reinforcement shall be provided within 1 to 2 in. (25 to 50 mm) of the tension faces of the wall. The area of this reinforcement shall be sufficient to resist the entire net flexural tension force. Maximum spacing of bonded reinforcement shall be three times the wall thickness or 12 in. (300 mm), whichever is greater.

Copyright by the American Water Works Association
Wed Feb 02 02:16:52 2005

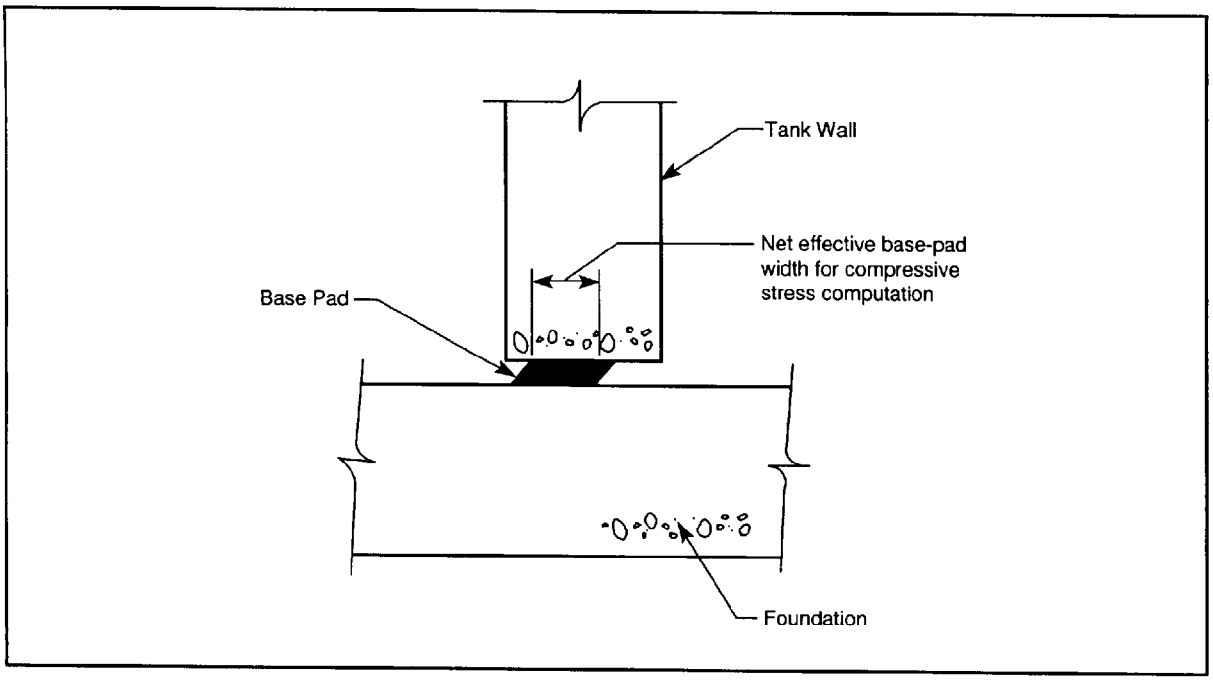

Figure 9 Net effective base-pad width after shear deformation

4.6.3 *Prestressing tensile stress.* For all tanks, the resultant tensile stress in the horizontal prestressed reinforcement under the combined effects of hydrostatic and hydrodynamic fluid pressure shall be not greater than $0.75f_{pu}$, where f_{pu} is the specified ultimate tensile strength of the wire or strand. The prestressed reinforcement shall be assumed to resist the entire net tension.

4.6.4 *Seismic-cable stress.* Maximum seismic-cable tensile stress shall not exceed $0.75f_{pu}$, where f_{pu} is the specified ultimate tensile strength of the strand.

4.6.5 *Base pad.* Maximum base-pad shear and compressive stresses shall not exceed the limits for occasional loading recommended by the manufacturer. The minimum width-to-thickness ratio for all pads and the minimum length-to-thickness ratio for discontinuous pads shall be 3.0. The net effective pad width after shear deformation (Figure 9) shall be used to compute the maximum compressive stress on the base pad.

Sec. 4.7 Maximum Allowable Coefficient of Friction

4.7.1 *Base-joint friction.* The coefficient of friction μ between concrete and an elastomeric pad shall not be less than 0.5 to compute maximum allowable base-pad, service-load, frictional resistance.

Sec. 4.8 Serviceability Requirements

4.8.1 *Uplift limitation.* Tanks without vertical or diagonal ties between the wall and footing shall not be permitted to have tension due to uplift from earthquake-induced overturning moment. For no uplift, the overturning moment M must be less than or equal to $r(W_S+W_R)$.

4.8.2 *Waterstop integrity.* For tanks with Figure 4B and 4C bases, the relative displacement between the tank shell and the foundation due to the combined effects of earthquake-induced base shear, gravity loads, and vertical accelerations shall not

Copyright by the American Water Works Association
Wed Feb 02 02:16:52 2005

exceed the capability of the waterstop to accommodate radial and tangential movement without leakage. Friction between the bearing pad and the wall base shall not be relied on to reduce the tangential displacements of the wall base in seismic zones 2B, 3, and 4.

4.8.3 *Seismic-cable sleeves.* For tanks with a Figure 4B base, compressible sponge rubber sleeves shall be used over the seismic cable through the base joint as specified to allow controlled radial wall movement.

Sec. 4.9 Foundation Design

4.9.1 *General.* Foundations shall be designed to resist gravity loads and the horizontal and vertical forces due to seismic forces induced by the design earthquake, acting simultaneously. Foundations for anchored flexible base tanks shall be designed to resist the seismic-cable uplift forces resulting from the earthquake-induced total shear, overturning moment, and gravity loads acting simultaneously. Foundations for all tanks shall be designed to resist the compressive forces resulting from the earthquake-induced overturning moment and gravity loads acting simultaneously.

4.9.2 *Soil stress.* A one-third increase in allowable soil stresses is permitted for load combinations that include seismic loads.

4.9.3 *Overturning moment.* The overturning moment in Sec. 4.3.1(2) is that applied to the base of the tank shell. The foundation is subjected to an additional moment due to the sloshing of the tank contents and the effect of dynamic fluid pressure on the tank bottom (see US Nuclear Regulatory Commission [1963] in appendix A) as well as an additional moment equal to the base shear times the vertical distance between the shell base and the resultant of the lateral soil load on the foundation.

The overall stability of the tank shall be investigated under maximum governing load combinations, including those due to seismic forces, and the stability against overturning achieved with a safety factor of 1.5 or greater. Under these conditions, the maximum soil stress under the foundation shall not exceed the allowable stress in Sec. 4.9.2. The tank foundation shall be designed for the resulting shear, flexure, and deflection.

Sec. 4.10 Minimum Freeboard

During a seismic event, the maximum water-surface displacement (sloshing height) may impinge on the underside of the roof slab. The anticipated unrestrained sloshing height shall be computed by Eq 4-28 or 4-29. If sufficient freeboard height is not provided to prevent uplift forces due to sloshing, the tank roof and its connections shall be designed for the uplift forces. The uplift forces generated by the restraint of sloshing shall be computed as the hydrostatic force produced by the liquid restrained from sloshing. The connection of the roof to the wall shall be designed for the resulting forces, and restraint provided if the uplift sloshing force exceeds 90 percent of the roof dead load on the wall.

$$d = ZIC_c r \qquad \text{(Eq 4-28)}$$

but need not exceed

$$d = \frac{3\, r \coth\left(\sqrt{3.375}\, H/r\right)}{\dfrac{6T_c^{\,2}}{ZIC_c\, r} - \sqrt{54}} \qquad \text{(Eq 4-29)}$$

Sec. 4.11 Design for Seismic Effects of Backfill

The dynamic seismic forces due to the backfill surrounding the tank, if any, shall be taken into account according to the soil-structure interaction criteria provided by the geotechnical engineer.

In a buried tank, the dynamic backfill forces shall not be relied on to reduce the dynamic effects of the water in the tank.

SECTION 5: CONSTRUCTION PROCEDURES

Sec. 5.1 Scope

The requirements for placing, finishing, and curing concrete and shotcrete shall be in accordance with the requirements of ACI 301, ACI 302.1R, ACI 304R, ACI 305R, ACI 306R, ACI 308, ACI 318, ACI 347R, ACI 350R, ACI 506R, and ACI 506.2, as modified herein, and additional requirements related specifically to wire- and strand-wound, circular, prestressed tank construction not included in these references.

Sec. 5.2 Concrete

5.2.1 *Weather limitations.*

5.2.1.1 Unless specifically authorized in writing, concrete shall not be placed during cold weather when the ambient temperature is below 35°F (2°C), even if the temperature is rising, or below 40°F (4°C) and falling, and when the concrete is likely to be subjected to freezing temperature before the concrete compressive strength has reached 500 psi (3.5 MPa). Most well-proportioned concrete will reach this strength when the temperature has been maintained at 50°F (10°C) into the second day after placement. Cold-weather concreting shall be in accordance with ACI 306R and ACI 301. The materials shall be heated so that the temperature of the concrete, when deposited, shall be not less than 50°F (10°C), or as otherwise indicated in ACI 306R, or more than 70°F (21°C). All methods and equipment for heating and for protecting concrete in place shall be subject to review by the purchaser.

5.2.1.2 During hot-weather concreting, cooling of water and aggregate shall be in accordance with the recommendations of ACI 305R.

5.2.1.3 Placement of concrete during periods of low humidity or high winds shall meet the requirements of ACI 301 and ACI 305R, particularly when large surface areas are to be finished. In any event, all concrete surfaces exposed to drying wind shall be covered with polyethylene sheets or acceptable wet covering immediately after finishing and shall be water cured in accordance with the requirements of ACI 308, continuously from the time the concrete has taken initial set. Water curing by ponding is the recommended method for curing water tank floors and shall be employed whenever practicable.

Curing compounds may be used in conjunction with water curing, provided they are compatible with coatings that may later be applied, or providing they are degradable or will be removed prior to the application of shotcrete or seal coatings. Curing compounds should not be permitted, under most circumstances, in lieu of water curing except for vertical surfaces such as cast-in-place core walls. Curing compounds used on the interior surfaces of tanks shall contain no constituents that will impart taste or odor, or other toxic chemicals to the water.

Copyright by the American Water Works Association
Wed Feb 02 02:16:53 2005

5.2.2 *Foundation preparation.* If the tank is to be constructed on undisturbed earth, all deleterious material should be removed during excavation for the tank floor and wall and column foundations. Confirm that the subgrade foundation material and its compaction are as specified in Sec. 3.8.4 and Sec. 3.9 for the tank construction. Under no circumstances should the earth be plowed, scraped, or dug by machinery in such a way that will result in the disturbance of material below grade, unless the earthwork specifications require its compaction in place or that it be removed and replaced with compacted imported material.

5.2.3 *Floor placement.* Check all reinforcing steel immediately prior to placing concrete to verify that the steel is properly positioned, adequately supported, and will have the specified concrete cover. If nonmetallic spacers (e.g., concrete "dobies" or plastic pads) are used between reinforcing bars and subgrade, verify that they are of adequate size, density, and number. Foot traffic should not be allowed on the reinforcing steel during the placing of the concrete unless the supports and ties are designed for that purpose. Temporary walkways for concrete placement should be adequately supported on the base material or formwork.

Concrete-membrane floors shall be cast continuously, without cold joints and, where practicable, without construction or expansion joints. Structural floors shall be cast continuously in sections of such size that once any placement begins, it will be completed without interruption. Waterstops shall be provided for all construction and expansion joints in concrete floor slabs. The free edge of a horizontal elastomeric waterstop shall be folded back until the concrete has been placed beneath it and compacted. The waterstop shall then be released and the concrete placement continued over it. Care shall be taken to avoid a downward deflection of the waterstop after it has been folded down on the previously placed and compacted concrete. Thickening the floor slab at the joint to a minimum of 8 in. (200 mm) will facilitate proper placement of the waterstop, but it may also contribute to shrinkage stresses that will require additional steel reinforcement in the thickened section. All top floor surfaces shall be to the line, grade, and finish specified.

Adequate curing of floors is critical to their proper construction and watertightness. During hot weather, floors shall be water cured in accordance with the requirements of ACI 308. In the absence of hot weather, water curing in accordance with ACI 308 shall be the preferred curing method, although membrane-forming curing compounds may be used in accordance with ACI 308 where conditions make it impractical to use water curing.

5.2.4 *Cast-in-place walls and columns.* Concrete cast-in-place walls and columns shall be placed in accordance with the requirements of ACI 301 or ACI 304. Each vertical segment of the tank wall shall be placed in a single continuous operation without horizontal joints. An enriched fine-aggregate mix shall be used at the base of columns and the base of the wall to improve embedment of the horizontal base waterstop and the reinforcement and bottom anchorages of vertical prestressing units. Care should be taken to assure subsequently placed concrete is vibrated into the enriched mixture.

5.2.4.1 Concrete shall be conveyed from mixer to forms by methods that minimize segregation or loss of ingredients. Concrete shall be deposited, as nearly as practicable, in its final position horizontally. There shall be no free vertical drop greater than 8 ft (2.4 m), except when starting a wall placement, in which case the free vertical drop of concrete shall not be more than 4 ft (1.2 m).

5.2.4.2 Concrete shall be placed before initial set has occurred and, unless otherwise acceptable to the purchaser, not later than 1½ h after adding water to the

Copyright by the American Water Works Association
Wed Feb 02 02:16:53 2005

AWWA D110 95 ■ 0783350 0503003 797 ■

mix when the air temperature is at 85°F (29°C) or above. This time period may be extended to a maximum of 2½ h provided the purchaser is satisfied that admixtures in sufficient quantity can extend the setting time of the concrete without adverse effects on the strength and quality of the concrete. When the air temperature is below 85°F (29°C), the 1½ h period may be extended by 1 min for each degree fahrenheit the air temperature is below 85°F (29°C). The time for placement shall not exceed a maximum of 2½ h after the water has first been added to the aggregate–cement mix.

5.2.4.3 Concrete shall not be placed in water, nor shall water be allowed to rise over freshly placed concrete, until after the concrete has set sufficiently to prevent damage to the mix or finish.

5.2.4.4 The forms shall be cleaned and coated with an approved nonstaining, nontoxic, bond release form oil before erection as specified in ACI 301. Concrete shall not be placed until all reinforcement is securely and properly fastened in position, the form ties at construction joints have been retightened, and all sleeves, hangers, pipe, bolts, and other items required to be embedded in the concrete have been placed and anchored. Exposed concrete edges, except vertical wall joints, shall have a ¾-in. (19-mm) chamfer.

5.2.4.5 Concrete shall be deposited in approximately horizontal layers or lifts not to exceed 24 in. (0.6 m) in depth. Before a new lift is placed, the concrete in the last lift shall be thoroughly and systematically vibrated. The vibrator shall penetrate the upper two lifts and shall be slowly pulled up. In other words, each lift before the final lift shall be vibrated twice. The final lift shall also be vibrated twice. Casting and vibrating of walls shall be done through form openings 18 in. by 18 in. (0.46 m by 0.46 m) minimum, located on one side of the wall.

5.2.4.6 All top surfaces shall be to line and grade and, unless otherwise specified, shall receive a smooth steel-trowel finish.

5.2.4.7 Walls shall be cured in accordance with the requirements of ACI 308.

5.2.4.8 All honeycombed concrete or concrete not meeting the requirements of ACI 301 shall be removed to sound concrete and repaired in accordance with ACI 301.

5.2.5 *Construction joints for cast-in-place concrete.*

5.2.5.1 Prior to the start of construction, the constructor shall submit for review layouts and details of all proposed joints in walls, floors, and footings, unless these details are shown on the contract drawings.

5.2.5.2 Spacing of vertical construction joints in concrete walls shall generally not exceed 60 ft (18 m). Shear keys, sleeved dowels, or continuous reinforcement shall be used in the joint to prevent radial displacement of adjacent wall panels or sections prior to prestressing. The face of the vertical joint where the horizontal nonprestressed-steel reinforcement is discontinuous at the joint shall be coated with bond breaker prior to placement of concrete for the adjacent wall section. All vertical construction joints in nondiaphragm tank walls shall have a suitable waterstop in the joint between the water and the prestressing wire or strand. Details of all joints shall be shown on the drawings. Joints between any two adjacent elements of the floor, wall, flat roof, and wall footing, and between floor and wall or between the wall and its footing, shall contain a suitable waterstop unless otherwise approved on the construction drawings submitted for the structure.

5.2.6 *Precast-concrete-panel wall.* Concrete for each precast panel shall be placed in one continuous operation.

5.2.7 *Precast-wall-panel erection.* The precast panels shall be erected to the correct vertical and circumferential alignment. The edges of adjoining panels shall

Copyright by the American Water Works Association
Wed Feb 02 02:16:53 2005

not vary inwardly or outwardly from one another by more than ⅜ in. (9.5 mm) and shall be placed to the tank radius, within like tolerance.

5.2.8 *Vertical joints between precast panels.* The edges of the diaphragms of adjoining panels shall be joined or lapped to form a watertight barrier. A steel sheet with lapped joints between diaphragm and steel sheet sealed with an elastomeric or epoxy sealing compound may be used to secure a watertight joint. The lapped joints between diaphragm sheets within each precast panel shall preferably be sealed by lock seaming with a roll form machine. The vertical slots between panels shall be filled with cast-in-place concrete, cement–sand mortar, or shotcrete compatible with the details of the joint. The strength of the concrete, mortar, or shotcrete shall be equal to that specified for concrete in the wall panels.

5.2.9 *Placement details for concrete in roofs.* Prior to construction, the constructor shall submit for review the proposed placement details and procedures, including the location and type of construction joints, unless these details and procedures are specified by the purchaser.

Sec. 5.3 Shotcrete

5.3.1 *Weather limitations.*

5.3.1.1 Placement of shotcrete may start without special protection when the ambient temperature is 35°F (2°C) and rising, but shall be suspended when the ambient temperature is 40°F (4°C) and falling. Placement of shotcrete when the ambient temperature is below 35°F (2°C) and rising, or below 40°F (4°C) and falling, shall be considered cold-weather shotcreting and shall not be allowed unless specifically authorized by the purchaser. Shotcrete shall not be placed on frozen surfaces. Cold-weather shotcreting shall be in accordance with ACI 306R and ACI 301. The materials shall be heated in order that the temperature of the shotcrete, when deposited, shall be not less than 50°F (10°C), or as otherwise recommended in ACI 306R, or more than 70°F (21°C). All methods and equipment for heating and for protecting shotcrete in place shall be subject to review by the purchaser.

5.3.1.2 For shotcrete placed during extremely hot weather, the aggregate shall be cooled by frequent spraying with water in such a manner as to use the cooling effect of evaporation without raising the moisture content above the level suitable for mixing and placement. During such periods, an acceptable placement schedule shall be arranged in a manner that will provide time for the temperature of the previously placed coat to begin to drop. The mixing water shall be the coolest available at the site, insofar as practicable. Hot-weather shotcreting shall be in accordance with the requirements of ACI 301 and the recommendations of ACI 305R.

5.3.1.3 Placement of shotcrete during periods of low humidity or high winds shall meet the requirements of ACI 301 and the recommendations of ACI 305R, particularly when large surface areas are to be placed. Roof domes and wall surfaces exposed to drying wind shall be water cured continuously in accordance with the requirements of ACI 308 from the time the shotcrete has taken initial set. Curing compounds may be used to assist in curing, but shall not be used in lieu of water curing, or on surfaces that are to receive additional shotcrete coatings.

5.3.2 *Placing and finishing.*

5.3.2.1 Dense, impermeable shotcrete is required for dome roofs in severe exposure conditions where condensation may occur on the underside of the roof. For this reason, dome roofs of dry-mix shotcrete shall not be used in areas subjected to freeze–thaw cycles. Where shotcreted dome roofs are allowed, roof shell thickness shall be controlled by positive methods, allowing a variation of +½ in. (13 mm). Dome thickness

Copyright by the American Water Works Association
Wed Feb 02 02:16:54 2005

AWWA D110 95 ■ 0783350 0503005 56T ■

shall not be less than specified. Dome joints shall be of the butt type, trimming the edge of that portion of the shotcrete above the mesh or bar reinforcement perpendicular to the form. The portion below shall be as close to perpendicular as placing techniques permit. The exposed joint shall be cleaned carefully with an air and water blast, and all loose material removed before placing the next section of shotcrete. Special attention should be given to the prevention of sand-pocket formation. Shotcrete dome roofs shall be continuously water cured in accordance with the requirements of one of the methods described in ACI 308.

5.3.2.2 Shotcrete walls shall be built up of individual layers of shotcrete no more than 2 in. (50 mm) thick. No less than two coats to a minimum total thickness of 1 in. (25 mm) shall be provided over the diaphragm on the inside of the tank. Under aggressive (corrosive) water conditions, additional protection shall be provided for the diaphragm.

5.3.2.2.1 Prior to placement of shotcrete, the constructor shall submit for the purchaser's review details of thickness-control procedures and aids. During application of shotcrete coats, the constructor shall demonstrate the effectiveness of the control procedures being used.

5.3.2.2.2 Shotcrete core-wall thickness shall be controlled by the use of vertical shooting wires (or line).

5.3.2.2.3 Vertical shooting wires (or line) for manual placement of shotcrete shall be installed under tension and spaced no more than 3 ft (0.9 m) apart to establish uniform and correct wall thicknesses. For machine-applied shotcrete, the shooting wires may be placed farther apart, as demonstrated by consistent and uniform application. Wires of 18- to 20-gauge (0.0475- to 0.0348-in. [1.21- to 0.88-mm]) high-tensile-strength steel or 150-lb (68-kg) test monofilament line shall be used. Shooting wires shall not be imbedded in the shotcrete surface. Should this occur, they shall be snapped loose. Shooting wires shall scribe the contour of the tank core wall from top to bottom, and shall not be removed until the cover-coat thickness has been confirmed by the purchaser's agent to be as specified. The specified finish may then be applied.

5.3.2.2.4 Shotcrete finish for the exterior wall surface may be any of the finishes in Sec. 5.3.3.5, as specified. Shotcrete finish for the inside-core-wall surface shall be smooth and well formed to facilitate cleaning of the tank and to reduce maintenance. The surface shall be a natural shotcrete finish followed by light brooming to remove pitting and surface roughness.

5.3.3 *Shotcrete protection of prestressed wire or strand.*

5.3.3.1 The primary purpose of the shotcrete wire and cover coats is for protection of the prestressed reinforcement against corrosion, both from the external environment and from materials used in the tank construction. Section 2.1.2 requires limiting the water-soluble chloride ion content in the concrete or shotcrete covering prestressed wire or strand to 0.06 percent of the weight of the cement in the mix. This requirement shall be adhered to rigidly.

Shotcrete for covering wire or strand shall be tested for water-soluble chloride content in accordance with the requirements of AASHTO T-260, unless previous test results substantiate that the allowable content will not be exceeded. Testing may be conducted on either the individual shotcrete ingredients or samples of the hardened shotcrete. Where local aggregates produce a mix that exceeds the 0.06 percent limitation, washing will normally reduce the chloride ion content to within acceptable limits for shotcrete placement; otherwise, aggregates must be imported.

Copyright by the American Water Works Association
Wed Feb 02 02:16:54 2005

5.3.3.2 Before beginning prestressing, voids or other defects on the core wall shall be repaired with mortar. Dust, efflorescence, oil, and other foreign material shall be removed from surfaces to be shotcreted. Concrete core walls shall have a bondable surface; attaining this will require sandblasting of the outside wall surface before wrapping. Sandblasting of concrete shall result in a heavily pitted bondable surface. Prior to wire or strand winding, and again before applying shotcrete cover coats, such materials as dirt, loose sand, and dust shall be removed from the wall surface and wire or strand, and the surface thoroughly dampened. Hardened shotcrete surfaces may be prepared by an air/water jet immediately before the next shotcrete coat is applied.

5.3.3.3 Each layer of circumferential prestressing shall be covered with a coat of fine-aggregate shotcrete wire coat as soon as practicable after prestressing. Nozzle distance and wetness of mix are equally critical to satisfactory encasement of prestressing wire or strand. The shotcrete shall be applied wet but not dripping.

5.3.3.3.1 Shotcrete shall be applied with the nozzle held at a small, upward angle, not exceeding 5°, and shall be constantly moved in a smooth motion during application, with the nozzle pointing in a radial direction toward the center of the tank. The nozzle distance from the prestressing shall be such that shotcrete does not build up or cover the front face of the wire or strand before the spaces behind and between the prestressing elements are filled. If the nozzle is held back too far, the shotcrete may deposit on the face of the prestressing elements at the same time that it is building on the core wall, thereby creating voids behind the wires or strand.

5.3.3.3.2 The appearance of a clearly defined pattern of continuous horizontal ridges at the prestressing elements after they are covered is an indication of insufficient shotcrete cover or of poor application and probable voids. If this occurs, the application of the wire coat shall be immediately suspended and the work carefully inspected by the purchaser. Corrective measures shall be implemented and completed prior to resuming the shotcreting operations. All improperly deposited shotcrete shall be removed prior to its final set and the shotcreting procedure corrected. The shotcreting procedure may be corrected by adjusting the nozzle distance and orientation perpendicular to the wall, or by adjusting the water content of the shotcrete mix. All shotcrete overspray shall be removed from the wall. The shotcreted surface shall be broomed and roughened, if needed, to ensure the proper bond of the subsequent applications. Rebound materials shall be removed from the work and shall not be reused in shotcreting.

5.3.3.3.3 Subsequent layers of circumferential prestressing and shotcrete wire or cover coats may be applied as soon as the underlying coat has developed sufficient bond and compressive strength to avoid damage.

5.3.3.3.4 Wire coat thickness shall be sufficient to provide a clear cover over the wire or strand of at least ¼ in. (6 mm) and in no case less than the diameter of the wire or strand.

5.3.3.4 Shotcrete shall be applied to provide a total thickness of not less than 1 in. (25 mm) over the last layer of wire or strand. The first coat placed over the wire shall be wire coat and the remaining cover coat(s) shall be wire or finish coat(s) applied as soon as possible after application of the last layer of wire coat. Intermediate cover coats and the finish coat shall be placed in thickness not exceeding 1 in. (25 mm).

Shotcrete cover coats shall be cut back 1 in. (25 mm) above the top of the footing or floor slab where movement may occur between the wall and floor or footing. Similarly, shotcrete shall be trimmed back from movable joints between the wall and

Copyright by the American Water Works Association
Wed Feb 02 02:16:54 2005

roof. Vertical shooting wires as specified in Sec. 5.3.2.2.3 shall be used to ensure positive control of the thickness.

5.3.3.5 One of the following shotcrete finishes shall be provided, as specified:

1. Natural gun.
2. Broomed.
3. Wood float.
4. Rubber float.

5.3.3.6 All exposed shotcrete coatings shall be kept moist for at least seven days. Each time a new wire or finish coating is applied, covering an underlying coat, a new seven-day curing period begins for the new coating, superseding the curing schedule on the prior shotcrete coating since its cure will proceed concurrently. Moist curing shall be started as soon as possible without damaging the shotcrete. Curing shall be by fog spraying or sprinkling and covering so as to keep the surface continuously damp, or by use of wetted burlap or cotton mats as specified in ACI 308. Curing by other means shall not be allowed. Curing may only be interrupted for subsequent application of prestressing and shotcreting that is to be applied prior to the end of the day. Remove any laitance that appears on the shotcrete surface after the curing period by using light sandblasting, air/water blasting, or other method acceptable to the purchaser.

5.3.4 *Control testing.* Quality control of shotcrete shall be in accordance with the applicable requirements of ACI 506R.

5.3.5 *Automated application.* In lieu of manually applied shotcrete, shotcrete may be applied by nozzles mounted on power-driven machinery located a uniform distance from the wall surface, traveling at a uniform speed around the wall circumference to provide the required coatings.

Sec. 5.4 Forming

5.4.1 *General.* Formwork shall meet the requirements of ACI 347R and ACI 301 unless modified by the purchaser in the project specifications.

5.4.2 *Wall form ties.* Form ties for wood forms shall have waterstops and shall be of the "snap-off breakback" type with conical- or spherical-type inserts 5/8 in. (16 mm) or more in depth. Flat bar ties used with steel form panels shall have plastic or rubber inserts to form a hole at least 1 in. (25 mm) deep for patching.

As soon as possible after the forms are removed, the tie holes on the interior wall surface shall be packed with nonmetallic, nonshrink, or epoxy mortar grout as specified in Sec. 2.1.5 and Sec. 2.10.1. The holes on the exterior of the wall shall be dry packed with portland-cement mortar as specified in Sec. 2.1.3.

Through bolts used for form ties shall be tapered for ease of removal and patching. If through bolts are used, the bolts shall be removed and the holes cleaned by sandblasting or wire brushing to remove all grease, bond breaker, or laitance. Bolt holes shall be vinyl plugged and patched with nonshrink or epoxy mortar grout in accordance with approved details. The outer 1 in. (25 mm) of the hole shall be patched with portland-cement grout that will provide a neutral or alkaline contact with the circumferential prestressing wire and strand.

5.4.3 *Dome-roof forms.* Dome forms shall be designed to resist all forces acting with respect to its sloped surfaces. The bracing required will be determined by the sequence of concrete or shotcrete placement and the rate at which it is placed. It is important to maintain proper curvature of the shell to avoid flat spots. Except for the outermost set of forms, formwork for concrete or shotcrete domes shall not be

Copyright by the American Water Works Association
Wed Feb 02 02:16:55 2005

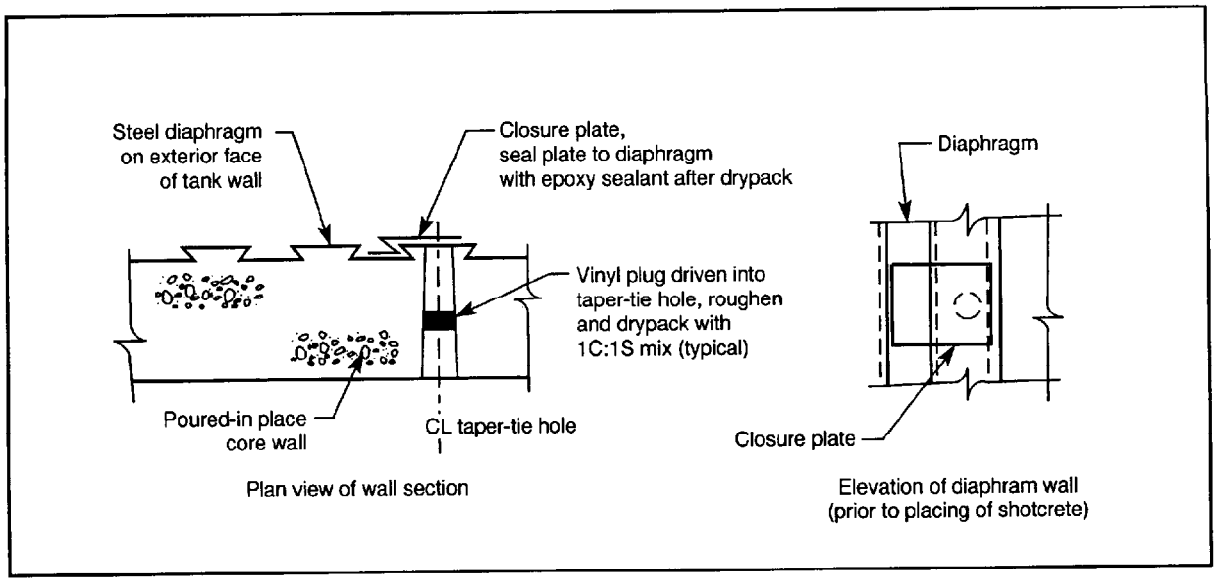

Figure 10 Diaphragm patching detail for type IV tank core wall

removed until the concrete or shotcrete is of sufficient strength and a circumferential prestressing force sufficient to support the dead load and a nominal construction live load has been applied to the dome edge ring.

5.4.4 *Metal diaphragms.* All vertical joints between metal diaphragms shall be sealed to form watertight joints without voids. When the diaphragm form performs as a vertical form (type II core wall), it shall be braced and supported in a manner sufficient to eliminate vibrations that would cause sloughing of the shotcrete during application. When it is necessary to penetrate the diaphragm, such as for installation of form ties in type IV core wall tanks, the penetrations shall be covered and sealed with epoxy after removal of the ties and patching of the tie holes. The patching shall result in a watertight barrier that will withstand water pressure the full height of the tank (see Figure 10).

Sec. 5.5 Nonprestressed-Steel Reinforcement and Vertical Tendons

5.5.1 *General.* Steel reinforcement shall be placed in conformance with ACI 301. For those tanks with vertical posttensioning tendons in the wall, and where the design requires radial movement of the wall with relation to the footing, the posttensioning units shall be supported prior to concrete or shotcrete placement in such a way that this wall movement will not be restricted. The posttensioning units shall be supported from the nonprestressed circular reinforcement, from the wall forms, or on plastic or mortar pads placed on the elastomeric bearing pad.

5.5.2 *Concrete and shotcrete cover.* The minimum cover over steel diaphragms, welded-wire fabric reinforcement, and tendon anchorages shall be as specified in Sec. 3.5.6.3.

Sec. 5.6 Prestressing

5.6.1 *Circumferential stressing.*

5.6.1.1 These paragraphs cover the application of high-tensile steel wire or strand, wound under tension by machines, around cylindrical concrete or shotcrete

Copyright by the American Water Works Association
Wed Feb 02 02:16:55 2005

walls, or dome edge rings to place the concrete or shotcrete in compression. An essential feature of this stressing system is the proper application of tension to the prestressed reinforcement as it is placed on the wall.

5.6.1.2 Field handling and storage of prestressing wire and strand shall be such that they are fully protected from physical damage and corrosion before, during, and after placement. Such protection, particularly for nongalvanized steel wire, shall include enclosed, ventilated, temporary storage facilities where weather conditions warrant. In no event shall materials be stored on the ground or covered with polyethylene or other membrane cover that will permit condensation to form on the steel.

5.6.1.3 A stressing system shall be used that is capable of consistently producing a stress at any point around the wall, falling within ±7 percent tolerance of the specified initial stress. Understressed wire or strand shall be compensated for as specified in Sec. 5.6.1.8.

5.6.1.4 Each coil of prestressing wire or strand shall be temporarily anchored at sufficient intervals to minimize the loss of prestress in case a wire or strand breaks during wrapping. Anchor clamps on the outer prestressing wrap shall be removed after application of the wire coat and shall not be permanently buried in the shotcrete cover coats.

5.6.1.5 Ends of individual coils shall be joined by suitable steel-splicing devices capable of developing the full strength of the wire or strand.

5.6.1.6 Stress shall not be applied to either the concrete or shotcrete core wall or dome-roof edge ring by the prestressing operation until they attain a strength of at least 1.8 times the compressive stress being applied. The minimum curing period prior to stressing shall be subject to acceptance by the purchaser.

5.6.1.7 A calibrated stress-measuring device that can be easily recalibrated shall be used frequently to determine wire or strand stress levels during the wrapping process. At least one stress reading for every coil or a minimum of one per foot of wall height shall be taken immediately after application on the wall, and all such readings shall be on straight lengths of wire or strand. Readings should refer to the applicable height and layer of wire or strand for which stress is being recorded. A written record of stress readings shall be maintained until all stressing is completed and the cover coats have been applied. The record shall then be delivered to the purchaser. A stress-recording device, which continuously and accurately measures and records the stress as the wire or strand is placed, may be substituted for the above-described method. The recording device shall be calibrated by an independent laboratory prior to each project.

5.6.1.8 If measured wire or strand stress falls below design f_{si}, additional prestress wire or strand shall be applied. If the applied stress of the wire or strand exceeds 1.07 f_{si}, the wrapping operation shall be discontinued immediately on discovery of this condition and satisfactory adjustment made to the stressing equipment before proceeding. The total prestress force measured on the wall per vertical foot of height shall not be less than the specified force distributed as shown on the force diagram submitted for the structure, nor more than 5 percent greater.

5.6.1.9 The force diagram for the tank wall shall be prepared for minimum spacing of the horizontal prestressing elements of $\frac{3}{8}$ in. (9.5 mm). The minimum clear space between wires or strands on the wall shall be $\frac{5}{16}$ in. (8 mm) or 1.5 wire or strand diameters, whichever is greater. Any wires or strands not initially meeting the spacing requirements shall be respaced or removed. Wires or strands in areas adjacent to openings or inserts shall be uniformly spaced in accordance with the

Copyright by the American Water Works Association
Wed Feb 02 02:16:56 2005

above. The band of prestressed reinforcement normally required over the height of an opening shall be displaced into circumferential bands immediately above and below the opening to maintain the required total circumferential prestressing force. Banded prestressed reinforcement causes vertical wall-bending effects that shall be taken into account in the design. Prestressing elements shall be placed no closer than 2 in. (50 mm) from the top of the wall or from edges of openings or inserts, nor closer than 3 in. (75 mm) from the base of wall, where radial movement may occur between wall base and floor or footing. Bundling of wires or strands shall be prohibited.

5.6.2 *Vertical wall stressing.*

5.6.2.1 These paragraphs provide recommendations for the application of high-tensile tendons as vertical prestressed reinforcement in cast-in-place tank walls, or linear prestressing tendons of precast panels through pretensioning or posttensioning techniques that are not covered by ACI 318.

5.6.2.2 All field handling of tendons and associated stressing and grouting equipment shall be under the direction of an individual with a technical knowledge of prestressing principles, i.e., one who has qualifying experience with the particular system or systems of posttensioning being used.

5.6.2.3 Field handling and storage of tendons and component parts on the jobsite shall be such that they are fully protected against physical damage and corrosion before, during, and after placement. Such protection shall include enclosed, dry, ventilated temporary storage when weather conditions warrant. In no event shall materials be stored on the ground or covered with polyethylene or other membrane cover that will permit condensation to form on the steel.

5.6.2.4 Tendons shall be handled and placed as follows:

5.6.2.4.1 Generally, tendons or tendon ducts shall be placed on the ground as near as possible to their final positions, then hoisted into final positions and secured. Neither tendons nor tendon ducts shall be dragged over supporting reinforcement, previously placed tendons, or ducts. A planned placing sequence considering supplemental reinforcements will preclude the need to thread tendons or ducts through previously placed reinforcing steel. Ducts shall be carefully inspected immediately prior to concreting to ensure against mortar leakage or indentations that would restrict the free movement of the tensioning steel during the stressing operation. No welding or burning shall be permitted in the vicinity of the prestressing steel, and the prestressed steel shall not be used as an electrical ground.

5.6.2.4.2 The duct sheathing for vertical tendons shall be tied to horizontal reinforcing steel or supported from the formwork to prevent displacement during concrete placement. Vertical tendons supported from the upper terminals require forms sufficiently strong to support their weight. Vertical tendon ducts shall be flushed with water immediately after concrete placement to ensure that the lower grout or epoxy injection ports remain unobstructed.

5.6.2.5 Tendons shall not be stressed until the concrete core wall attains a strength sufficient to sustain the concentration of bearing stresses under the anchorage plates without damage to the wall materials. The permissible compressive stress in the concrete shall be calculated as indicated in the PTI Post-Tensioning Manual, and shall not exceed 1.25 f'_{ci} at transfer load, nor 1.25 f'_c at service load. The minimum curing period prior to stressing shall be subject to acceptance by the purchaser.

5.6.2.6 Grout shall be injected under pressure in vertical tendon ducts from the lower duct terminal. Openings or voids in the anchorages shall be plugged to prevent grout leakage and the ensuing loss of pressure during the grouting operation.

Copyright by the American Water Works Association
Wed Feb 02 02:16:56 2005

AWWA D110 95 ■ 0783350 0503011 863 ■

Grout riser tubes or suitable alternative containment shall be attached at the top of vertical tendon ducts to ensure that the duct remains full, thus permitting grout settlement to take place in the riser or other containment rather than in the duct. Grout shall be injected into the tendon duct immediately after the tendon has been stressed. When epoxy is used as encasement for the vertical tendons, the application will be similar and shall be as recommended by the manufacturer.

Sec. 5.7 Wall Tolerances

The maximum out-of-round tolerance for shotcrete, cast-in-place concrete, and precast-concrete panel walls shall be based on the ratio of ±½ in., –0. (+12.5 mm, –0) per 100-ft (30-m) diameter circle and the circumference shall be a smooth curve. Tolerance in wall thickness shall be + ½ in., –0 (+12.5 mm, –0). Wall thickness shall not be less than specified. All transitions shall be gradual and smooth. Walls shall be plumb within a tolerance not exceeding ⅜ in. (9.5 mm) per 10 ft (3 m) of vertical dimension.

Sec. 5.8 Seismic Cables

5.8.1 *General.* When the tank design requires seismic cables in separated floor–wall connections, the galvanized or epoxy-coated cables (strand) shall be installed between the base of the wall and the footing. Sleeves of sponge rubber or other suitable material shall surround the strands for the specified distance on each side of the joint to permit radial wall movements. Sleeves shall be positively sealed to prevent grout entry.

5.8.2 *Placing.* Cables shall be cut to uniform lengths and prebent, if necessary, for proper placement in the footing forms. Care shall be taken in placement to avoid compression of the bearing pad and restraint of radial wall movement. Cable units shall be securely tied to the nonprestressed wall reinforcement to prevent displacement as the concrete or shotcrete is placed.

Sec. 5.9 Waterstops

Waterstops shall be centered in the joints and secured by split forms or other acceptable means to ensure positive positioning. Horizontal waterstops that are accessible during concreting shall be secured in a manner that allows them to be bent up while concrete is placed and compacted underneath, after which the waterstop shall be allowed to return to position and concrete immediately placed over the waterstop. Waterstops that are not accessible during concreting shall be positively tied in such a manner that bending in either direction is prevented. Judicious use of nails or "hog-ties" driven through the edges of waterstops to facilitate placing and tying may be permitted. All waterstops shall be spliced by heat welding in a manner that ensures complete continuity as a water barrier.

Sec. 5.10 Elastomeric Bearing Pads

Bearing pads shall be positively positioned prior to wall placement and secured with an approved adhesive to prevent their being uplifted during concrete or shotcrete placement. Pads in cast-in-place concrete walls shall also be held in position by inserting small, dense concrete blocks or plastic shims under vertical reinforcing steel where possible. Nailing of pads shall not be permitted unless the pads are specifically designed for such anchorage and nailing does not restrict lateral deformation. Where bearing pads are used, the tank wall shall be free of all

Copyright by the American Water Works Association
Wed Feb 02 02:16:56 2005

obstructions that would prevent free radial movement at the joint. The remaining voids between cast-in-place concrete or shotcrete wall and wall footing (or roof) shall be filled with a suitable closed-cell neoprene or rubber filler material and a caulking compound to positively prevent mortar from entering the joint.

Sec. 5.11 Sponge Fillers

Sponge fillers for cast-in-place concrete walls shall be 15 percent wider than required to fill the spaces between wall faces, bearing pads, and waterstops. The method of securing sponge-filler pads shall be the same as for elastomeric bearing pads. All voids shall be caulked with a suitable nontoxic sealant that bonds securely to all surfaces of pad, filler, and waterstop. Particular attention shall be paid to the filling and sealing of the joint between the bearing pad and waterstop.

Sec. 5.12 Disinfection

Disinfection of the completed tank shall follow the criteria found in ANSI/AWWA C652.

Sec. 5.13 Watertightness

On completion of the tank, and prior to any specified backfill placement at the footing or wall, the following test shall be applied to determine watertightness:

5.13.1 *Preparation.* Fill the tank with potable water to the maximum level and let it stand for at least 24 h.

5.13.2 *Measurement.* Measure the drop in liquid level over the next 72 h to determine the liquid volume loss for comparison with the allowable leakage. Evaporative losses shall be measured or calculated and deducted from the measured loss to determine the net liquid loss (leakage). The net liquid loss for a period of 24 h shall not exceed 0.05 of 1 percent of the tank capacity.

5.13.2.1 If the leakage exceeds the maximum allowable, the leakage test shall be extended to a total of five days. If at the end of five days the average daily leakage does not exceed the maximum allowable, the test shall be considered satisfactory. If the net liquid loss exceeds the maximum allowable, leakage shall be considered excessive and the tank shall be repaired, redisinfected, and retested until leakage falls within the appropriate limit.

5.13.2.2 Damp spots on the exterior wall surface or measurable leakage of water at the wall base shall not be permitted. Damp spots are defined as spots where moisture can be picked up on a dry hand. The source of water movement through the wall shall be located and permanently sealed in an acceptable manner. Leakage through the wall-base joint or footing shall likewise be corrected. Damp spots on the footing are generally to be expected, and are permissible.

Sec. 5.14 Repairs

The constructor shall make all necessary repairs if the tank fails the watertightness test or is otherwise defective. The method of repair shall be subject to acceptance by the purchaser.

5.14.1 *Concrete repair.* The most common repair method for small areas of honeycombed concrete (rock pockets) and other defective concrete is removal and replacement with nonshrink aggregate grout (which may include pea gravel aggregate) bonded to the concrete with an epoxy bonding agent. The minimum strength of material used in the repair shall equal or exceed that specified for the concrete.

Copyright by the American Water Works Association
Wed Feb 02 02:16:57 2005

AWWA D110 95 ■ 0783350 0503013 636 ■

Defective tie hole patches shall be removed and the holes repacked or epoxy injected.

5.14.2 *Epoxy injection grouting.*

5.14.2.1 Wall repair. Damp or wet spots resulting from leakage through the wall shall be repaired with a high-pressure epoxy injection grouting system or other method acceptable to the purchaser. When epoxy grouting is to be performed, a low-viscosity, two-component, water-insensitive, nontoxic epoxy-resin system with an in-line metering and mixing system shall be used. The pumps shall be capable of producing a minimum injection pressure of 100 psi (680 kPa). Injection pressure shall be limited to 300 psi (2.1 MPa) to ensure complete penetration of the defect without damaging the structure. Epoxy shall reach a minimum compressive strength of 6,000 psi (40 MPa) in 24 h in accordance with the requirements of ASTM D695. An applicator with successful past experience in water-retaining structures shall be present on the job at all times while repairs are being made. Work shall be guaranteed against failure of the epoxy bond in the repair areas for a minimum period of one year.

Any exposed defect receiving epoxy repair shall first be cleaned of dirt, laitance, and other material that might prevent proper bonding. A suitable temporary seal shall then be applied to the surface of the defect to prevent the escape of the epoxy. Entry ports shall be spaced along the seal at intervals not greater than the thickness of the cracked element. The epoxy shall be injected into the crack at the lowest port first, with sufficient pressure to advance the epoxy to an adjacent port, using a small nozzle held tightly against the port. The operation shall continue until epoxy material begins to extrude from the adjacent port. The original port shall be sealed and the injection shall be repeated in one continuous operation until the crack has been injected with epoxy for its entire length. All ports, including adjacent locations where epoxy seepage occurs, shall be sealed as necessary to prevent drips and runouts. On completion of the injection of the crack, the grout shall be allowed to cure for sufficient time to allow the removal of the temporary seal without any draining or running out of the adhesive epoxy material from the crack. The surface of the crack shall then be finished flush with the adjacent surfaces and shall show no indentations or evidence of port filling.

5.14.2.2 Floor, piping, and valves. Generally the loss of water through the tank floor, piping, and valves is difficult to determine separately. The total loss shall not exceed the criteria set forth in Sec. 5.13.2. If the loss of water exceeds the criteria, the tank floor shall be inspected for point sources of leakage with the tank full or empty.

Water loss through floor joints or shrinkage cracks shall be located and the defective sections removed and replaced, or repaired by epoxy injection grouting as specified earlier or by other means acceptable to the purchaser. Any potential point sources of leakage found shall be repaired and the watertightness test repeated.

Sec. 5.15 Tank Backfill

When wall backfill is required, it shall be initiated only after the tank has been satisfactorily tested and filled, unless another procedure is acceptable to the purchaser. Backfill material shall be placed in uniform layers and compacted to the satisfaction of the purchaser for the material and site conditions prevailing. Avoid unbalanced backfill placement variation in elevation around the tank except as may be fully provided for in the design.

Copyright by the American Water Works Association
Wed Feb 02 02:16:57 2005

Sec. 5.16 Clean Up

The premises shall be kept clean and orderly at all times during the work, and, on completion of construction, the constructor shall remove or otherwise dispose of all rubbish and other unsightly material caused by the construction operations. The constructor shall leave the premises in as good a condition as they were found.

Sec. 5.17 Electrical Grounding

Electrical grounding to the nonprestressed reinforcing steel or prestressed reinforcement for any equipment or electrical service shall be strictly prohibited.

SECTION 6: INSPECTION PROCEDURES

Sec. 6.1 Scope

This section provides procedures for field observation (inspection) of wire- or strand-wound, circular, prestressed concrete water tanks during construction, after construction, and during routine maintenance. ACI SP-2 and the appropriate requirements of ACI 318 shall be followed unless modified by this standard. The observer is to confirm that materials and construction techniques being used by the tank constructor are those approved by the purchaser. The presence of the purchaser's agent, and inspection and acceptance of the water tank, does not relieve the constructor from compliance with plans and specifications. Some suggestions for maintenance repairs are also included in this section.

Sec. 6.2 Field Observation During Construction

6.2.1 *General.* The purpose of field observation during construction is to assist the constructor in interpretating the plans and specifications and to verify that the constructor is complying with the plans and specifications. The goal is to ensure that the completed tank is structurally sound, has adequate protection for the nonprestressed steel reinforcement and prestressed steel elements, and is watertight. The construction procedures given in Sec. 5 are for the guidance of both the constructor and the observer. Section 6 provides additional guidance for field observation of those phases of construction requiring the greatest care to ensure creation of a well-constructed tank. Accurate and detailed records of all phases of construction should be kept and maintained for future reference of the purchaser and the constructor or design-constructor.

6.2.2 *Critical items.* Close observation of the following items is essential because of their importance to the corrosion resistance and structural integrity of the tank.

6.2.2.1 Confirm that the foundation for the tank has been prepared in accordance with the procedures of Sec. 5.2.2. Witness testing of all underfloor piping for watertightness in conformance with the specifications, and the placement and compaction of trench backfill and floor base material. Check all formwork for wall and column footings and the reinforcement for tank floor placement.

6.2.2.2 Review tests for all concrete, shotcrete, admixtures, and patching materials for conformance with the specifications and absence of water-soluble ions in excess of the limitations of Sec. 2.1. Verify tolerances on wall form construction and placement of reinforcement.

Copyright by the American Water Works Association
Wed Feb 02 02:16:57 2005

Verify that all form ties and through bolts are of the type specified in Sec. 5.4.2.

Observe the placement of concrete and shotcrete of the approved mix proportions, slump, and air entrainment, and the steps taken to prevent segregation and achieve dense, impervious tank elements. Verify proper cleaning and patching of wall tie or bolt holes, initiated as soon as possible after removal of formwork and curing of the walls. Witness cleaning and patching procedures using approved materials in accordance with approved details and manufacturers' instructions.

6.2.2.3 Check all waterstop installations prior to concrete placement to verify that they are properly located in the joints, adequately secured, and fully fused together at the joints as specified. For horizontal waterstops accessible during concrete casting, verify that the free edge of the waterstop is lifted and the concrete is placed and compacted underneath the waterstop before any placement over the waterstop. The upper free edge of the waterstop in the floor-to-wall joint should be tied at approximately 12-in. (300-mm) maximum intervals to a securely fastened, horizontal reinforcing bar of size 4 or larger or otherwise secured to avoid displacement. It is extremely important that all waterstops are fully embedded in the concrete and that no voids remain.

6.2.2.4 If elastomeric pads are used between the tank wall and floor or footing ring, or between the tank roof and tank wall, see that the pads are properly positioned and secured before concrete is cast or precast concrete panels are placed. After placement, verify that the wall joint is free of any obstructions that would interfere with radial wall movement.

6.2.2.5 Prior to any wire or strand wrapping or shotcreting of the core wall, verify that all voids 1 in. (25 mm) or more in depth, honeycombed concrete, and other defects are completely cut out to solid concrete and dry-packed with mortar. Be sure that all dust, efflorescence, oil, and other foreign material is removed by sandblasting. Verify that the edges of precast panels are in alignment as specified in Sec. 5.2.7, and that all vertical slots between precast wall panels are filled with the specified cement–sand mortar, fine-aggregate concrete, or shotcrete in accordance with the approved details.

6.2.2.6 Make certain that vertical prestressing of the core wall is done prior to circumferential prestressing, but not until the core wall attains the strength specified in Sec. 5.6.2.5.

6.2.2.7 Verify that circumferential prestressing is not applied until the core wall and the shotcrete or grout in the vertical joints for precast wall sections reach a strength at least 1.8 times the compressive stress being applied. Ensure that wire anchors are not contacting the reinforcing bars by checking the anchor holes before the anchors are inserted. Prestressed wire or strand shall be electrically isolated from all other metallic structural elements. All anchors and clamps used with galvanized wire or strand should be galvanized steel. By direct measurement, verify that minimum wire spacing described in Sec. 5.6.1.9 is maintained. Measurement and recording of wire stress levels during the wrapping process are two of the most important tasks of field observation. Confirm that the measuring device is correctly calibrated as described in Sec. 5.6.1.7 and that stress levels are in compliance with the specifications as described in Sec. 5.6.1.8.

6.2.2.8 Confirm that the shotcrete mix complies with specifications, that the method of application and minimum thickness of the wire coats and cover coats are correct prior to removing of the shooting wires, and that there are no voids behind the wire or strand. See Sec. 5.3.3.

Copyright by the American Water Works Association
Wed Feb 02 02:16:58 2005

6.2.2.8.1 As the shotcrete wire coat is being applied, visually observe the application of the coating to verify that proper encasement of the prestressed elements has been achieved in accordance with Sec. 5.3.3.3. Continuous monitoring of the application is recommended.

6.2.2.8.2 Checking for proper cover-coat thickness and bond are two of the most important tasks of field observation. Verify that vertical shooting wires are installed in the proper position to obtain the specified cover-coat thickness prior to applying the shotcrete. Verify the shooting wire spacing, tension, and distance from the final wire or strand wrap before shotcreting. After the coating has cured, check the surface of the shotcrete finish coat for hollow-sounding or "drummy" spots by tapping with a light hammer or similar tool. Such spots may indicate a lack of bond between coats and may need to be repaired prior to tank acceptance by the purchaser. If patching is extensive and an exterior coating is not specified, an additional shotcrete finish coat may be required to achieve an acceptable appearance.

6.2.2.8.3 If an exterior coating is specified to be applied over the shotcrete cover or finish coat, remove all laitance or other foreign material by sandblasting, water blasting, or other acceptable method prior to applying the coating.

6.2.2.9 The tank shall be disinfected, prior to checking for leakage, in accordance with Sec. 5.12, unless more rigid standards are mandated by state or local authorities, or by the purchaser.

Sec. 6.3 Inspection After Construction

Observe the leakage test to determine the watertightness of the tank, and conduct a visual inspection to verify that all work has been satisfactorily completed and all appurtenances installed in accordance with the plans and specifications.

6.3.1 *Watertightness.* Testing for watertightness shall be in accordance with Sec. 5.13. The weather must be dry in order to observe leakage. Particular attention shall be given to the ground surface around the tank and at the perimeter drains for evidence of leakage through the floor, the floor–wall connection, or around piping. To verify the source of the water from a suspected leak, it may be necessary to check for chlorine or to use a dye or nontoxic paint inside the tank. A knowledgeable scuba diver or hard-hat diver and use of underwater lights will often provide the most efficient way to locate leaks. Sometimes a diver can locate a leak by placing a waterproof membrane or sterile white cotton ball over a suspicious crack or floor joint. For tanks that are to remain in service, it may be desirable to employ a hard-hat or scuba diver with a wet or dry suit that can be sterilized before entry into the water in order to protect treated water from contamination due to body contact. It is recommended that this diver be equipped for underwater photography to detect and locate cracks that open only under hydrostatic loading. Personnel should never be permitted to enter a tank for underwater inspection without carefully observing safety procedures, such as guarding or valving off all outlets, providing suitable lighting, and other appropriate protective measures.

6.3.2 *Wall leaks.* Unless the purchaser approves another procedure, the wall shall be carefully inspected for any evidence of damp spots prior to placement of any backfill over the wall footing or against the wall, and under full head to the overflow level. The location and cause of all visible leakage and damp spots shall be carefully noted and made a matter of record prior to proceeding with repair.

6.3.3 *Repairs.* All repairs shall be made in accordance with Sec. 5.14. All repair work shall be inspected while in progress and on completion.

Sec. 6.4 Inspection During Routine Maintenance

A wire- or strand-wound prestressed tank should be inspected after the first year of service, at any time that there are such visible problems as leaks or cracks, or routinely every 5 to 10 years following the initial inspection. Inspections should preferably take place during months when tank surfaces are dry and groundwater is at a minimum. The initial step should consist of valving off the tank, verifying the leakage rate by measuring a drop in the water surface, and comparing this with the initial test at the time of construction. The inspection should include the following items:

6.4.1 *Wall.* Physically examine the exterior surface to locate any signs of possible deterioration or corrosion, including rust stains, efflorescence, cracks, or leaks. Wide-angle binoculars are helpful in examining those portions of the wall not accessible by ladder or scaffolding. "Sound test" the shotcrete cover coat at areas or signs of deterioration for evidence of separation or "disbonding" from the core wall as specified in Sec. 6.2.2.8.2. Carefully record the location and severity of these signs of possible trouble. Color photographs and/or video tape are valuable additions to the written record. Repair all leaks, as described in Sec. 5.14.

6.4.2 *Floor.* For aboveground tanks, a visual inspection of the ground surface around the tank may reveal any leakage through the floor, at the floor–wall connection, or at piping. If a subdrain system has been installed under the floor, water flowing from this system can be checked for chlorine content and leakage rate. This is particularly important for buried tanks. Leaking from cracks or joints in the floor or from the floor–wall connection of a buried or partially backfilled tank may only be detected from inside the tank when the tank is full. Scuba divers can sometimes locate these cracks by evidence of silt buildup at small cracks, or by observation of clean lines at the larger cracks. The diver can release an indicator, such as a nontoxic dye or a sterile white cotton ball, at a suspected leak. The indicator verifies the leak if it moves toward the crack or if it appears outside the tank. All leaks should be promptly repaired.

6.4.3 *Roof.* The interior and exterior of the roof should be physically examined for any signs of rust, efflorescence, cracks, or spalling. Monitors, manholes, or other roof penetrations should be inspected for rust, cracks, or leakage. All spalled areas and cracks in the top surface over $\frac{1}{16}$ in. (1.5 mm) wide, where leakage through the roof may occur, should be repaired. If leakage is evident, cracks should be repaired with pumped epoxy as described in Sec. 5.14 or a suitable nontoxic roof sealant should be applied to protect the reinforcing steel and maintain water quality. Sealant at expansion joints in flat slab roofs should be carefully inspected. If joint leakage or disbonded sealant is observed, the sealant should be removed and replaced.

6.4.4 *Further inspection.* If the scheduled inspection shows rusting, cracking (other than surface crazing), or evidence of leakage on the exterior of the wall, small areas of shotcrete should be removed at selected locations and the prestressed wire or strand examined for corrosion damage. At least six areas should be selected for inspection of the prestressed reinforcement, based on the location of rust stains, wet areas, and evidence of disbonding of the shotcrete cover coat and cracks or spalling, as well as areas above or below any wall penetrations. Each exposure should be a minimum of 8 in. (200 mm) square. If no wire or strand damage is found at any of the six exposures, the shotcrete can be repaired with a dry-pack cement–sand mortar or epoxy grout and then the other routine maintenance work can proceed. If reinforcement damage is found at one or more exposures, then additional exposures should be made until enough information is obtained to determine if the tank has been structurally weakened.

Copyright by the American Water Works Association
Wed Feb 02 02:16:58 2005

The inspection should be performed under the direction of a professional engineer thoroughly familiar with wire- or strand-wound prestressed tanks and their construction. After the engineer's review of this information, a decision should be made as to whether or not additional remedial work is needed.

Preface

This preface, as well as all footnotes and annexes, is included for informational purposes and is not part of ANSI/ISA-75.01-1985 (R1995).

This standard has been prepared as part of the service of the ISA, the international society for measurement and control, toward a goal of uniformity in the field of instrumentation. To be of real value, this document should not be static, but should be subject to periodic review. Toward this end, the Society welcomes all comments and criticisms, and asks that they be addressed to the Secretary, Standards and Practices Board, ISA, 67 Alexander Drive, P.O. Box 12277, Research Triangle Park, NC 27709, Telephone (919) 990-9227; Fax (919) 549-8288; E-mail: standards@isa.org.

The ISA Standards and Practices Department is aware of the growing need for attention to the metric system of units in general, and the International System of Units (SI) in particular, in the preparation of instrumentation standards, recommended practices, and technical reports. The Department is further aware of the benefits to USA users of ISA standards of incorporating suitable references to the SI (and the metric system) in their business and professional dealings with other countries. Toward this end, this Department will endeavor to introduce SI-acceptable metric units in all new and revised standards to the greatest extent possible. *The Metric Practice Guide*, which has been published by the Institute of Electrical and Electronics Engineers as ANSI/IEEE Std 268-1992, and future revisions, will be the reference guide for definitions, symbols, abbreviations, and conversion factors.

It is the policy of ISA to encourage and welcome the participation of all concerned individuals and interests in the development of ISA standards, recommended practices, and technical reports. Participation in the ISA standards-making process by an individual in no way constitutes endorsement by the employer of that individual, of ISA, or of any of the standards, recommended practices, and technical reports that ISA develops.

1 Scope

This standard presents equations for predicting the flow of compressible and incompressible fluids through control valves. The equations are not intended for use when mixed-phase fluids, dense slurries, dry solids, or non-Newtonian liquids are encountered. In addition, the prediction of cavitation, noise, or other effects is not a part of this standard.

2 Introduction

The equations of this standard are based on the use of experimentally determined capacity factors obtained by testing control valve specimens according to the procedures of ANSI/ISA S75.02, "Control Valve Capacity Test Procedure" (see Annex J—References).

The equations are used to predict the flow rate of a fluid through a valve when all the factors, including those related to the fluid and its flowing condition, are known. When the equations are used to select a valve size, it is often necessary to use capacity factors associated with the fully open or rated condition to predict an approximate required valve flow coefficient (C_v). This procedure is further explained in Annex A.

2.1 Flow variable and fluid properties

The flow rate of a fluid through a control valve is a function of the following (where applicable):

a) Inlet and outlet conditions

   1) Pressure
   2) Temperature
   3) Piping geometry

b) Liquid properties

   1) Composition
   2) Density
   3) Vapor pressure
   4) Viscosity
   5) Surface tension
   6) Thermodynamic critical pressure

c) Gas and vapor properties

   1) Composition
   2) Density
   3) Ratio of specific heats

d) Control valve properties

   1) Size
   2) Valve travel
   3) Flow path geometry

Copyright by the The Instrumentation, Systems, and Automation Society
Wed Feb 02 02:19:44 2005

3 Nomenclature

Symbol	Description
C_v	Valve flow coefficient
d	Valve inlet diameter
D	Internal diameter of the pipe
F_d	Valve style modifier
F_F	Liquid critical pressure ratio factor, dimensionless
F_k	Ratio of specific heats factor, dimensionless
F_L	Liquid pressure recovery factor of a valve without attached fittings, dimensionless
F_{LP}	Product of the liquid pressure recovery factor of a valve with attached fittings (no symbol has been identified) and the piping geometry factor, dimensionless
F_P	Piping geometry factor, dimensionless
F_R	Reynolds number factor, dimensionless
F_s	Laminar, or streamline, flow factor, dimensionless
g	Local acceleration of gravity
G_f	Liquid specific gravity at upstream conditions [ratio of density of liquid at flowing temperature to density of water at 60°F (15.6°C)], dimensionless
G_g	Gas specific gravity (ratio of density of flowing gas to density of air with both at standard conditions, which is equal to the ratio of the molecular weight of gas to the molecular weight of air), dimensionless
k	Ratio of specific heats, dimensionless
K	Head loss coefficient of a device, dimensionless
K_B	Bernoulli coefficient, dimensionless
K_i	Velocity head factors for an inlet fitting, dimensionless
M	Molecular weight, atomic mass units
N_1, N_2, etc.	Numerical constants for units of measurement used
p_1	Upstream absolute static pressure, measured two nominal pipe diameters upstream of valve-fitting assembly
p_2	Downstream absolute static pressure, measured six nominal pipe diameters downstream of valve-fitting assembly
Δp	Pressure differential, $p_1 - p_2$
p_c	Absolute thermodynamic critical pressure
p_r	Reduced pressure, dimensionless
p_v	Absolute vapor pressure of liquid at inlet temperature
p_{vc}	Apparent absolute pressure at vena contracta
q	Volumetric flow rate
q_{max}	Maximum flow rate (choked flow conditions) at a given upstream condition

Copyright by the The Instrumentation, Systems, and Automation Society
Wed Feb 02 02:19:44 2005

Symbol	Description
Re_v	Valve Reynolds number, dimensionless
T_r	Reduced temperature, dimensionless
T_c	Absolute thermodynamic critical temperature
T_1	Absolute upstream temperature (in degrees K or R)
U_1	Velocity at valve inlet
w	Weight or mass flow rate
x	Ratio of pressure drop to absolute inlet pressure ($\Delta p/p_1$), dimensionless
x_T	Pressure drop ratio factor, dimensionless
x_{TP}	Value of x_T for valve-fitting assembly, dimensionless
Y	Expansion factor, ratio of flow coefficient for a gas to that for a liquid at the same Reynolds number, dimensionless
Z	Compressibility factor, dimensionless
γ_1 (gamma)	Specific weight, upstream conditions
μ (mu)	Viscosity, absolute
ν (nu)	Kinematic viscosity, centistokes
ρ (rho)	Density

Subscripts

1	Upstream conditions
2	Downstream conditions
s	Nonturbulent
t	Turbulent

4 Incompressible fluid — flow of nonvaporizing liquid

The flow rate of a liquid through a given control valve at a given travel is a function of the differential pressure ($p_1 - p_2$) when the liquid does not partially vaporize between the inlet and outlet of the valve. If vapor bubbles form either temporarily (cavitation) or permanently (flashing), this relationship may no longer hold. (Refer to Section 5 for choked flow equations that apply when extensive vaporization occurs.) In the transitional region between nonvaporizing liquid flow and fully choked flow, the actual flow rate is less than that predicted by either the equations in this section or those in Section 5. Cavitation that occurs in this transitional region can produce physical damage to the valve and/or to the downstream piping and equipment.

Copyright by the The Instrumentation, Systems, and Automation Society
Wed Feb 02 02:19:44 2005

4.1 Equations for turbulent flow

The equations for determining the flow rate of a liquid through a valve under turbulent, nonvaporizing flow conditions are:

$$q = N_1 F_p C_v \sqrt{\frac{p_1 - p_2}{G_f}}$$

or

$$C_v = \frac{q}{N_1 F_p \sqrt{\frac{G_f}{p_1 - p_2}}} \qquad \text{(Eq. 1)}$$

$$w = N_6 F_p C_v \sqrt{(p_1 - p_2)\gamma_1}$$

or

$$C_v = \frac{w}{N_6 F_p \sqrt{(p_1 - p_2)\gamma_1}} \qquad \text{(Eq. 2)}$$

4.2 Numerical constants *N*

The numerical constants *N* are chosen to suit the measurement units used in the equations. Values for *N* are listed in Table 1.

Table 1 — Numerical constants for liquid flow equations

Constant		Units Used in Equations					
N		*w*	*q*	*p*, Δ*p*	*d*, *D*	γ_1	ν
N_1	0.0865	—	m^3/h	kPa	—	—	—
	0.865	—	m^3/h	bar	—	—	—
	1.00	—	gpm	psia	—	—	—
N_2	0.00214	—	—	—	mm	—	—
	890	—	—	—	in	—	—
N_4	76 000	—	m^3/h	—	mm	—	centistokes*
	17 300	—	gpm	—	in	—	centistokes*
N_6	2.73	kg/h	—	kPa	—	kg/m^3	—
	27.3	kg/h	—	bar	—	kg/m^3	—
	63.3	lb/h	—	psia	—	lb/ft^3	—

*To convert m^2/s to centistokes, multiply m^2/s by 10^6. To convert centipoises to centistokes, divide centipoises by G_f.

Copyright by the The Instrumentation, Systems, and Automation Society
Wed Feb 02 02:19:44 2005

4.3 Piping geometry factor F_p

The piping geometry factor F_p accounts for fittings attached to either the valve inlet or the outlet that disturb the flow to the extent that valve capacity is affected. F_p is actually the ratio of the flow coefficient of a valve with attached fittings to the flow coefficient (C_v) of a valve installed in a straight pipe of the same size as the valve.

For maximum accuracy, F_p must be determined by the test procedures specified in ANSI/ISA S75.02 (see Annex J—References). Where estimated values are permissible (see Baumann reference, *Effect of Pipe Reducers on Control Valve Capacity*), F_p may be determined by using the following equation:

$$F_p = \left(\frac{\Sigma K C_v^2}{N_2 d^4} + 1 \right)^{-1/2} \qquad \text{(Eq. 3)}$$

(See Annex B for the mathematical derivation of F_p.)

In many instances, the nominal sizes for valve and pipe (d and D) may be used in Equations 3, 5, 6, and 7 without significant error.

The factor ΣK is the algebraic sum of the effective velocity head coefficients of all fittings attached to but not including the valve. For instance,

$$\Sigma K = K_1 + K_2 + K_{B1} - K_{B2} \qquad \text{(Eq. 4)}$$

where K_1 and K_2 are the resistance coefficients of the inlet and outlet fittings, respectively, and K_{B1} and K_{B2} are the Bernoulli coefficients for the inlet and outlet fittings, respectively. The Bernoulli coefficients compensate for the changes in pressure resulting from differences in stream area and velocity.

When the diameters of the inlet and outlet fittings are identical, $K_{B1} = K_{B2}$, both factors drop out of the equation. When the diameters of the inlet and outlet fittings are different, K_B is calculated as follows:

$$K_B = 1 - \left(\frac{d}{D} \right)^4 \qquad \text{(Eq. 5)}$$

The fittings most commonly encountered are standard, short-pattern concentric pipe reducers. These fittings have little taper, and their pressure loss will not exceed that of an abrupt contraction with a slightly rounded entrance. On that basis, if experimental values for the resistance coefficients K_1 and K_2 are unavailable, estimated values may be computed as follows:

Inlet reducer only:

$$K_1 = 0.5 \left(1 - \frac{d^2}{D_1^2} \right)^2 \qquad \text{(Eq. 6)}$$

Outlet increaser only:

$$K_2 = 1.0 \left(1 - \frac{d^2}{D_2^2} \right)^2 \qquad \text{(Eq. 7)}$$

Copyright by the The Instrumentation, Systems, and Automation Society
Wed Feb 02 02:19:45 2005

When the reducer and increaser are the same size:

$$K_1 + K_2 = 1.5\left(1 - \frac{d^2}{D^2}\right)^2 \qquad \text{(Eq. 8)}$$

(See Annex C for a graphic representation of system head changes around a valve with attached reducers.)

4.4 Equations for nonturbulent flow

Nonturbulent flow occurs at high fluid viscosities and/or low velocities. In these circumstances, the flow rate through a valve is less than for turbulent flow, and the Reynolds number factor F_R must be introduced. F_R is the ratio of nonturbulent flow rate to the turbulent flow rate predicted by Equations 1 or 2. The corresponding nonturbulent equations then become, respectively:

$$q = N_1 F_R C_v \sqrt{\frac{p_1 - p_2}{G_f}}$$

or

$$C_v = \frac{q}{N_1 F_R \sqrt{\frac{p_1 - p_2}{G_f}}} \qquad \text{(Eq. 9)}$$

$$w = N_6 F_R C_v \sqrt{(p_1 - p_2)\gamma_1}$$

or

$$C_v = \frac{w}{N_6 F_R \sqrt{(p_1 - p_2)\gamma_1}} \qquad \text{(Eq. 10)}$$

Note the absence of the piping geometry factor in the above equations. For nonturbulent flow, the effect of close-coupled reducers or other flow-disturbing fittings is unknown. Thus, Equation 3 applies to turbulent flow only.

Tests (see Stiles reference, *Liquid Viscosity Effects on Control Valve Sizing*, and McCutcheon reference, *A Reynolds Number for Control Valves*) show that F_R can be found by using the valve Reynolds number and Figure 1. The shading around the central curve indicates the scatter of test data and the range of uncertainty of flow rate prediction in the nonturbulent regimes.

The valve Reynolds number is defined as:

$$\mathrm{Re}_v = \frac{N_4 F_d q}{\nu F_L^{1/2} C_v^{1/2}}\left(\frac{F_L^2 C_v^2}{N_2 d^4} + 1\right)^{1/4} \qquad \text{(Eq. 11)}$$

The valve style modifier F_d in Equation 11 correlates data from tests of several valve styles with different hydraulic radii, so that a single curve represents all the styles tested. (See Annex D for representative values of F_d.) Caution must be used in applying the curve in Figure 1 to valve styles for which F_d has not been established.

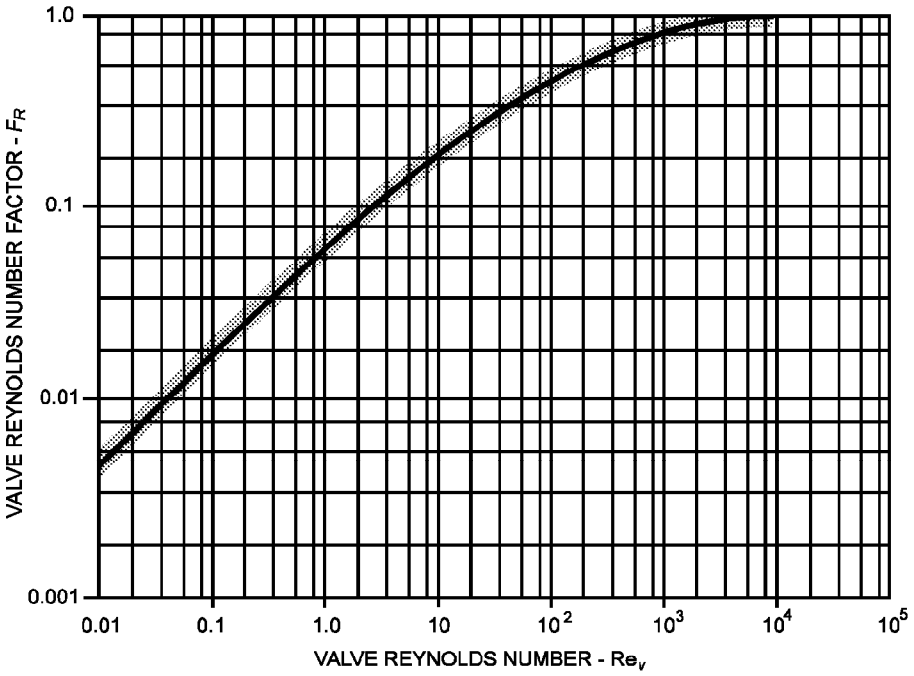

Figure 1 — Reynolds number factor

The bracketed term in Equation 11 accounts for the *velocity of approach**. Except for wide-open ball or butterfly valves, this term has only a slight effect on the Re_v calculation and can generally be omitted.

Most flow streams in process plant control valves are turbulent, with valve Reynolds numbers in excess of 10^4, where the Reynolds number factor is 1.0. When the flow regime is questionable, Equation 11 should be used to find Re_v. For additional information on nonturbulent flow, see Annexes E and F.

5 Incompressible fluid — choked flow of vaporizing liquid

Choked flow is a limiting, or maximum, flow rate. With fixed inlet (upstream) conditions, it is manifested by the failure of decreasing downstream pressure to increase the flow rate. With liquid streams, choking occurs as a result of vaporization of the liquid when the pressure within the valve falls below the vapor pressure of the liquid. Choked flow will be accompanied by either cavitation or flashing. If the downstream pressure is greater than the vapor pressure of the liquid, cavitation occurs. If the downstream pressure is equal to or less than the vapor pressure of the liquid, flashing occurs. This relationship between flow rate and pressure drop for a typical valve is shown in Figure 2.

*The flow rate through a valve is a function of the velocity of the jet stream at the vena contracta and the area of the jet at that location. This velocity is a function of the pressure drop across the valve orifice and also the valve inlet velocity, or *velocity of approach*. The velocity of approach factor is included in the valve flow coefficient C_v.

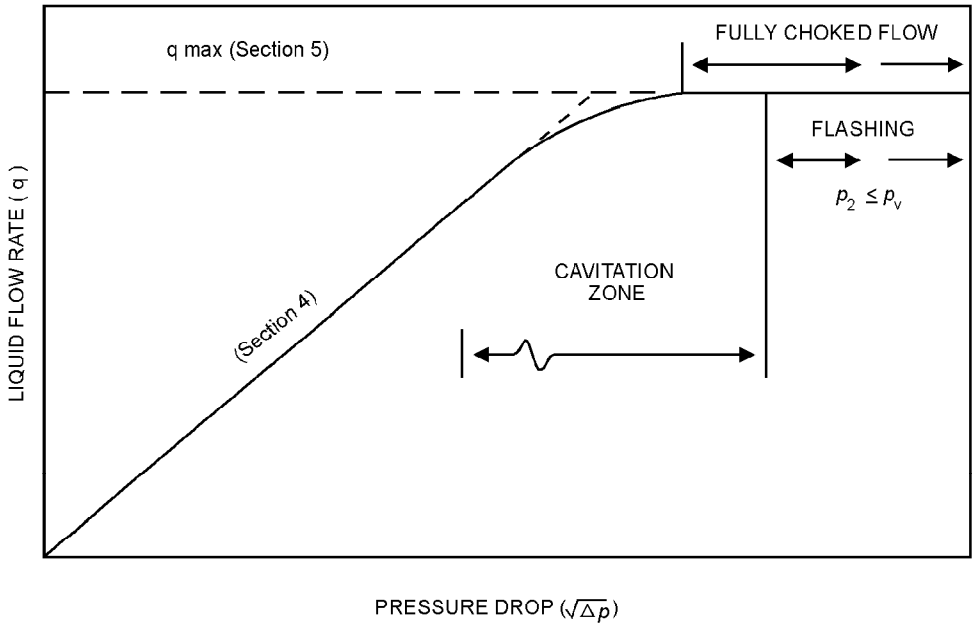

Figure 2 — Liquid flow rate versus pressure drop for a typical valve (constant upstream pressure and vapor pressure)

5.1 Liquid choked flow equations

The equations for determining the maximum flow rate of a liquid under choked conditions for valves in straight pipes of the same size are as follows:

$$q_{max} = N_1 F_L C_v \sqrt{\frac{p_1 - p_{vc}}{G_f}}$$

or

$$C_v = \frac{q_{max}}{N_1 F_L \sqrt{\frac{G_f}{p_1 - p_{vc}}}} \qquad \text{(Eq. 12a)}$$

where

$$p_{vc} = F_F p_v \qquad \text{(see Annex G for } F_F\text{)} \qquad \text{(Eq. 13a)}$$

giving

$$q_{max} = N_1 F_L C_v \sqrt{\frac{p_1 - F_F p_v}{G_f}}$$

or

$$C_v = \frac{q_{max}}{N_1 F_L \sqrt{\frac{G_f}{p_1 - F_F p_v}}} \qquad \text{(Eq. 14a)}$$

Wed Feb 02 02:19:47 2005

The equations for determining the maximum flow rate of a liquid under choked conditions for valves with attached fittings are:

$$q_{max} = N_1 F_{LP} C_v \sqrt{\frac{p_1 - p_{vc}}{G_f}}$$

or

$$C_v = \frac{q_{max}}{N_1 F_{LP} \sqrt{\frac{p_1 - p_{vc}}{G_f}}}$$

(Eq. 12b)

where

$$p_{vc} = F_F p_v \qquad \text{(see Annex G for } F_F\text{)}$$

(Eq. 13b)

giving

$$q_{max} = N_1 F_{LP} C_v \sqrt{\frac{p_1 - F_F p_v}{G_f}}$$

or

$$C_v = \frac{q_{max}}{N_1 F_{LP} \sqrt{\frac{p_1 - F_F p_v}{G_f}}}$$

(Eq. 14b)

5.2 Liquid pressure recovery factor F_L

The liquid pressure recovery factor F_L applies to valves without attached fittings (see Baumann reference, *The Introduction of a Critical Flow Factor for Valve Sizing*). This factor accounts for the influence of the internal geometry of the valve on its capacity at choked flow. Under nonvaporizing flow conditions, it is defined by the equation:

$$F_L = \sqrt{\frac{p_1 - p_2}{p_1 - p_{vc}}} \qquad \text{(Eq. 15a)}$$

Representative F_L values for various valve styles are listed in Annex D.

5.3 Combined liquid pressure recovery factor F_{LP}

When a valve is installed with reducers or other attached fittings, the liquid pressure recovery of the valve-fitting combination is not the same as that for the valve alone. For calculations involving choked flow, it is convenient to treat the piping geometry factor (F_p) and the F_L factor for the valve-fitting combination as a single factor, F_{LP}. The value of F_L for the combination is then F_{LP}/F_p, where

$$\frac{F_{LP}}{F_p} = \sqrt{\frac{p_1 - p_2}{p_1 - p_{vc}}} \qquad \text{(Eq. 15b)}$$

(Refer to Section 4.3 and Annex B.)

For maximum accuracy, F_{LP} must be determined by using the test procedures specified in ANSI/ISA S75.02 (see Annex J—References). When estimated values are permissible, reasonable accuracy may be obtained by using the following equation to determine F_{LP}:

$$F_{LP} = F_L\left(\frac{K_i F_L^2 C_v^2}{N_2 d^4} + 1\right)^{-1/2} \qquad \text{(Eq. 16)}$$

In this equation, K_i is the head loss coefficient ($K_1 + K_{B1}$) of any fitting between the upstream pressure tap and the inlet face of the valve only. (See Annex B for the mathematical derivation of F_{LP}.)

6 Compressible fluid — flow of gas and vapor

The flow rate of a compressible fluid varies as a function of the ratio of the pressure differential to the absolute inlet pressure ($\Delta p/p_1$), designated by the symbol x. At values of x near zero, the equations in this section can be traced to the basic Bernoulli equation for Newtonian incompressible fluids. However, increasing values of x result in expansion and compressibility effects that require the use of appropriate correction factors (see Buresh and Schuder reference, *The Development of a Universal Gas Sizing Equation for Control Valves*, and Driskell reference, *New Approach to Control Valve Sizing*).

6.1 Equations for turbulent flow

The flow rate of a gas or vapor through a valve may be calculated by using any of the following equivalent forms of the equation:

$$w = N_6 F_p C_v Y \sqrt{x p_1 \gamma_1}$$

or

$$C_v = \frac{w}{N_6 F_p Y \sqrt{x p_1 \gamma_1}} \qquad \text{(Eq. 17)}$$

$$q = N_7 F_p C_v p_1 Y \sqrt{\frac{x}{G_g T_1 Z}}$$

or

$$C_v = \frac{q}{N_7 F_p p_1 Y} \sqrt{\frac{G_g T_1 Z}{x}} \qquad \text{(Eq. 18)}$$

$$w = N_8 F_p C_v p_1 Y \sqrt{\frac{xM}{T_1 Z}}$$

or

$$C_v = \frac{w}{N_8 F_p p_1 Y} \sqrt{\frac{T_1 Z}{xM}} \qquad \text{(Eq. 19)}$$

$$q = N_9 F_p C_v p_1 Y \sqrt{\frac{x}{M T_1 Z}}$$

or

$$C_v = \frac{q}{N_9 F_p p_1 Y} \sqrt{\frac{M T_1 Z}{x}} \qquad \text{(Eq. 20)}$$

Note that the numerical value of x used in these equations must not exceed the choking limit ($F_K x_{Tp}$), regardless of the actual value of x. (See Section 6.4.)

6.2 Numerical constants *N*

The numerical constants N are chosen to suit the measurement units used in the equations. Values for N are listed in Table 2.
