NONMETALLIC FLAT GASKETS FOR PIPE FLANGES

1 SCOPE

This Standard for nonmetallic flat gaskets for bolted flanged joints in piping includes:

(*a*) types and sizes;
(*b*) materials;
(*c*) dimensions and allowable tolerances.

2 TYPES

Dimensions are provided for the following types of gaskets which are suitable for use with the flange facings indicated:

Gasket Type	Flange Facing
full face	flat face flanges
flat ring	raised face

3 SIZES

The sizes of flanges for which dimensions are given in the tables are included in the standards listed under para. 5.3.[1] Those sizes are expressed in nominal pipe size (NPS) as described in ANSI/ASME B36.10 M.

4 MATERIALS

4.1 Composition

Gaskets shall be made of resilient or pliable materials. Metal may be incorporated as reinforcing or filler material.

4.2 Service Requirements

Selection of a suitable material for a given service is the responsibility of the user, subject to the requirements of the referenced standard (see para. 5.3) and any applicable code or government regulation. The material selected shall be compatible with the fluid and suitable for the pressure-temperature conditions of the service.

5 DIMENSIONS

5.1 Thickness

Selection of gasket thickness is the responsibility of the user, considering the properties of the gasket material as well as the intended service application.

5.2 Diameters

The tabulated diameters are based on the following:

(*a*) The outside diameter of flat ring gaskets is equal to the bolt circle diameter minus the bolt diameter so that the gasket is centered in the flange bolts.

(*b*) The outside diameter of full face gaskets is equal to the flange outside diameter.

(*c*) The inside diameter of all gaskets is equal to the outside diameter of pipe required by ANSI/ASME B36.10M.[2]

5.3 Dimensional Tables

Tables are provided for each of the following referenced flange standards.

5.3.1 ASME/ANSI B16.1 Cast Iron Pipe Flanges and Flanged Fittings

(*a*) Table 1 (Class 25) and Table 2 (Class 125) provide dimensions for flat rung and full face gaskets.

(*b*) Table 3 (Class 250) provides dimensions for flat ring gaskets.

[1] Standards and specifications referenced in this Standard are listed in Annex A. The specific edition is not identified in text references. Instead, the edition reference is specified in Annex A.

[2] The user may require that the inside diameter of the gasket matches the inside diameter of the pipe.

72	72.00	81.38	86.50	60	1.25	82.50
84	84.00	94.25	99.75	64	1.38	95.50
96	96.00	107.25	113.25	68	1.38	108.50

GENERAL NOTE: Dimensions are in inches.

5.3.2 ASME/ANSI B16.5 Pipe Flanges and Flanged Fittings

(*a*) Dimensions in Tables 4 and 5 also apply to flanged valves (ASME/ANSI B16.34).

(*b*) Table 4 (Class 150) provides dimensions for flat ring and full face gaskets.

(*c*) Table 5 (Classes 300, 400, 600, and 900) provides dimensions for flat ring gaskets.

5.3.3 ASME B16.24 Cast Copper Alloy Pipe Flanges and Flanged Fittings. Table 6 provides dimensions for full face gaskets.

5.3.4 ASME B16.47 Large Diameter Steel Flanges

(*a*) Table 7 provides flat ring gasket dimensions for Series A (formerly MSS SP-44) flanges, Classes 150, 300, 400, and 600.

(*b*) Table 8 provides flat ring gasket dimensions for Series B (formerly API Standard 605) flanges, Classes 75, 150, 300, 400, and 600.

5.3.5 MSS SP-51 Class 150 LW Corrosion Resistant Cast Flanges and Flanged Fittings

(*a*) Table 9 provides dimensions for full face gaskets.

(*b*) These dimensions apply also to MSS SP-42 valves.

6 TOLERANCES

Outside diameter
NPS 12 and smaller: +zero, −0.06 in.
NPS 14 and larger: +zero, −0.12 in.

Inside diameter
NPS 12 and smaller: ±0.06 in.
NPS 14 and larger: ±0.12 in.

Bolt circle diameter: ±0.06 in.

Center-to-center of adjacent bolt holes: ±0.03 in.

ADOPTION NOTICE

ASME-B16.24, "Flanges, Cast Copper Alloy Pipe, and Flanged Fittings," was adopted on October 3, 1994 for use by the Department of Defense (DoD). Proposed changes by DoD activities must be submitted to the DoD Adopting Activity: Commanding Officer, Naval Construction Battalion Center, Code 156, 1000 23rd Avenue, Port Hueneme, CA 93043-4301. DoD activities may obtain copies of this standard from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094. The private sector and other Government agencies may purchase copies from the American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017.

Date of Issuance: April 15, 1991

The 1991 edition of this Standard is being issued with an automatic addenda subscription service. The use of an addenda allows revisions made in response to public review comments or committee actions to be published as necessary; revisions published in addenda will become effective 6 months after the Date of Issuance of the addenda. The next edition of this Standard is scheduled for publication in 1996.

ASME issues written replies to inquiries concerning interpretations of technical aspects of this Standard. The interpretations will be included with the above addenda service. Interpretations are not part of the addenda to the Standard.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Consensus Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that the determination of the validity of any such patent rights, and the risk of the infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

FOREWORD

(This Foreword is not part of ASME B16.24-1991.)

The development of the first Bronze Flanged Standard was started in 1910 to eliminate the confusion prevailing in the trade with respect to bronze flange dimensions and service ratings. The work culminated and was published in 1914 under the title "1914 Brass Standard Flange Dimensions" for 150 and 250 lb steam pressures.

This was superseded in 1928 by the Manufacturers Standardization Society of Valves and Fittings Industry (MSS) "Standard Practice" SP-2 which contained changes to provide interchangeability with the American Cast-Iron Flange Standards for 125 lb and 250 lb steam pressures. Subsequent revisions were issued in 1930 and 1936. In the latter a new column of thickness for 300 lb flanges was added.

In the 1937 edition, illustrations and dimensions of bronze flanged fittings were added. This was edited and reprinted in 1943 to make it conform in effect to U.S. Department of Commerce, National Bureau of Standards, Simplified Practice Recommendation R-183-42 and to the War Production Board Limitation Order L-252, dated January 23, 1943.

In the 1946 edition, the pressure-temperature ratings were added for the 150 lb and 300 lb standards and the dimensions for and reference to the 250 lb standard were omitted. Limitation Order L-252 was cancelled on April 28, 1945. The period of Government prohibition of manufacture and civilian use of the 250 lb standard, during the life of Order L-252, caused no hardship on the part of either the manufacturer or the consumer, indicating that this pressure class in bronze products does not warrant being recognized as a standard.

This standard which has been kept up-to-date and in constant use since 1910, was reviewed and reaffirmed in 1949. In October, 1951, MSS presented it to Sectional Committee B16 on Pipe Flanges and Flanged Fittings for review and possible approval as an American Standard.

Following approval of the sectional committee and sponsor organizations, it was presented to the American Standards Association (ASA), now the American National Standards Institute (ANSI), for approval and designation as an American Standard. This was granted on February 27, 1953.

In 1961, following the organization of Subcommittee No. 11 (now J), work was begun on revision of the 1953 edition. Chief among the changes recommended was the deletion of reference to brass. This resulted from an action by the ASTM of redefining the alloys which could properly be called bronze. Several other changes which brought the standard up-to-date were also approved by the Sectional Committee and sponsor organizations, with approval designation as an American Standard being granted on July 20, 1962.

Subcommittee J, in keeping with regulations of ANSI began a review of the document in 1969. Only minor changes were found necessary. Among these were the presentation of ratings in tabular form, and the gasket retaining grooves being made permissible rather than recommended. Final approval to the changes was granted by ANSI on January 27, 1971.

A revision was undertaken in 1977 and several changes were proposed. Chief among

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:43 2005

these was the addition of metric equivalents and the elimination of the optional gasket retaining grooves. In addition, the standard was extensively revised editorially. Following approvals by Subcommittee J, the Standards Committee and Co-Secretariat, ANSI granted its approval on June 26, 1979.

In 1982 American National Standards Committee B16 was reorganized as an ASME Committee operating under procedures accredited by ANSI.

This 1991 edition of the standard changes the scope of the standard from bronze pipe flanges and fittings to cast copper alloy flanges and flanged fittings. The scope of the flanges now covered in this document was expanded to include classes 150, 300, 400, 600, 900, 1500 and 2500. This edition establishes U.S. customary units as the standard. Other clarifying and editorial revisions were made in order to improve the text.

Following approval by the Standards Committee and ASME, this revision to the 1979 edition of the Standard was approved as an American National Standard by ANSI on February 1, 1991, with the new designation ASME B16.24-1991 and the new title "Cast Copper Alloy Pipe Flanges and Flanged Fittings."

Request for interpretations or suggestions for revisions should be sent to the Secretary B16 Committee, The American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, N.Y. 10017.

CAST COPPER ALLOY PIPE FLANGES, FLANGED FITTINGS, CLASS 150, 300, 400, 600, 900, 1500 AND 2500

1 SCOPE

1.1 General

This Standard for Cast Copper Alloy Pipe Flanges and Flanged Fittings covers:

(a) pressure temperature ratings;
(b) sizes and methods of designating openings for reduced fittings;
(c) marking;
(d) materials;
(e) dimensions;
(f) bolts, nuts, and gaskets;
(g) tolerances; and
(h) tests.

1.2 Codes and Regulations

A flange or flanged fitting used under the jurisdiction of the ASME Boiler and Pressure Vessel Code, the ASME Code for Pressure Piping or a governmental regulation is subject to any limitation of that code or regulation. This includes any maximum temperature limitation, or rule governing the use of a material at low temperature, or provisions for operating at a pressure exceeding the pressure–temperature ratings in this Standard.

1.3 Units of Measurement

U.S. customary units are the standard. For conversion to metric units use the following:

(a) 1 in. = 25.4 mm
(b) 1 psi = 0.069 bar = 6.9 kPa
(c) °F = 1.8°C + 32

2 PRESSURE–TEMPERATURE RATINGS

2.1 General

The tabulated pressure–temperature ratings shown in Tables 1 and 2 apply to the materials designated in paras. 5.2.1, 5.2.2, 5.3.1, and 5.3.2, and to the dimensions prescribed in Tables 3, 4, 5, and 6. The tabulated pressure–temperature ratings shown in Table 1 apply to the materials designated in para. 5.2.3 and to the dimensions prescribed in ASME/ANSI B16.5. All ratings are independent of the contained fluid and are the maximum non-shock pressures at the tabulated temperatures. Pressure ratings at temperatures intermediate to those tabulated may be obtained by linear interpolation.

2.2 Ratings of Flanged Joints

Ratings in this Standard apply to flanged joints which conform to the limitations on bolting in paras. 5.4 and 8(a), and on gaskets in paras. 5.5 and 8(b) and which are made up in accordance with good practice for alignment and assembly. Use of the ratings for flanged joints not conforming to these limitations is the sole responsibility of the user. Requirements for alignment and assembly of joints and consideration of leakage due to forces and moments developed in the connected piping or equipment are not covered in this Standard. If the two flanges in a flanged joint do not have the same pressure–temperature ratings, the rating of the joint at any temperature is the lower of the two flange ratings at that temperature.

2.3 Rating Temperature

The temperature shown for a corresponding pressure rating is the temperature of the pressure-containing shell of the flange or flanged fitting. In general, this temperature is the same as that of the contained fluid. Use of a pressure rating corresponding to a temperature other than that of the contained fluid is the responsibility of the user, subject to the applicable code or regulation. For any temperature below −20°F, the rating shall be no greater than the rating for −20°F.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:44 2005

2.4 Low Temperature Service

When assembled with suitable bolting and gaskets, and subject to the applicable code or regulations, copper alloy flanges and flanged fittings, in accordance with this Standard, may be used at temperatures down to −325°F.

2.5 System Hydrostatic Test

Flanged joints and flanged fittings may be subjected to system hydrostatic tests at pressures not to exceed 1.5 times the tabulated working pressure at 100°F. System testing at higher pressures is the responsibility of the user, subject to the requirements of the applicable code or regulation.

3 SIZES AND METHOD OF DESIGNATING OPENINGS

3.1 The size of a regular flange or fitting is identified by the corresponding nominal pipe size, NPS.

3.2 Reduced fittings shall be designated by the size of the openings in their proper sequence as indicated in Fig. 1.

4 MARKING

4.1 General

Except as modified herein, flanges and flanged fittings shall be marked as required in MSS SP-25.

4.1.1 Name. The manufacturer's name or trademark shall be applied.

4.1.2 Material. All flanges and flanged fittings shall be marked with the ASTM specification number. In addition, the grade identification symbol, 952, is required for flanges cast to ASTM B 148.

4.1.3 Rating Class. Numerals shall be applied giving the pressure rating class for which the product is designed.

4.1.4 Designation. The designation "B16" shall be applied, preferably located adjacent to the Class designation, to indicate conformance to this Standard.

4.1.5 Size. The nominal pipe size shall be applied but may be omitted from reducing flanges and reducing flanged fittings.

5 MATERIALS

5.1 General

Products covered by this Standard shall be made of castings produced to the requirements of para. 5.2 or 5.3.

5.2 Flanges

Flanges shall be in accordance with one of the material requirements listed below.

5.2.1 Alloy C83600. Castings shall meet the requirements of ASTM B62.

5.2.2 Alloy C92200. Castings shall meet the requirements of ASTM B61.

5.2.3 Alloy C95200. Castings shall meet the requirements of ASTM B148 and the additional requirements listed below.

5.2.3.1 Ordering Information. Ordering information shall include tests on each lot and the form of the test bar.

5.2.3.2 Sampling. The sample for chemical analysis shall be taken from the test bar casting or other casting sample in such a manner as to be representative of each casting lot.

5.2.3.3 Test Bars. A minimum of three test bars shall be poured from each lot of cast metal.

5.2.3.4 Weld Repair Approval. A flange casting shall not be repaired, plugged, welded, or burned-in unless permission from the user of the flange has been previously secured. This will be requested of the user upon the manufacturer's determination that casting defects are such that after the approved repair the usefulness and the strength of the casting will not be impaired.

5.2.3.5 Weld Repair. Preparation for repair welding shall include inspection to assure complete removal of the defect. Repairs shall be made utilizing welding procedures qualified in accordance with Section XI of the ASME Boiler and Pressure Vessel Code. Repair welding shall be done by welders or welding operators meeting the qualification requirements of that Code.

5.3 Flanged Fittings

Flanged fittings shall be in accordance with one of the material requirements listed below.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:44 2005

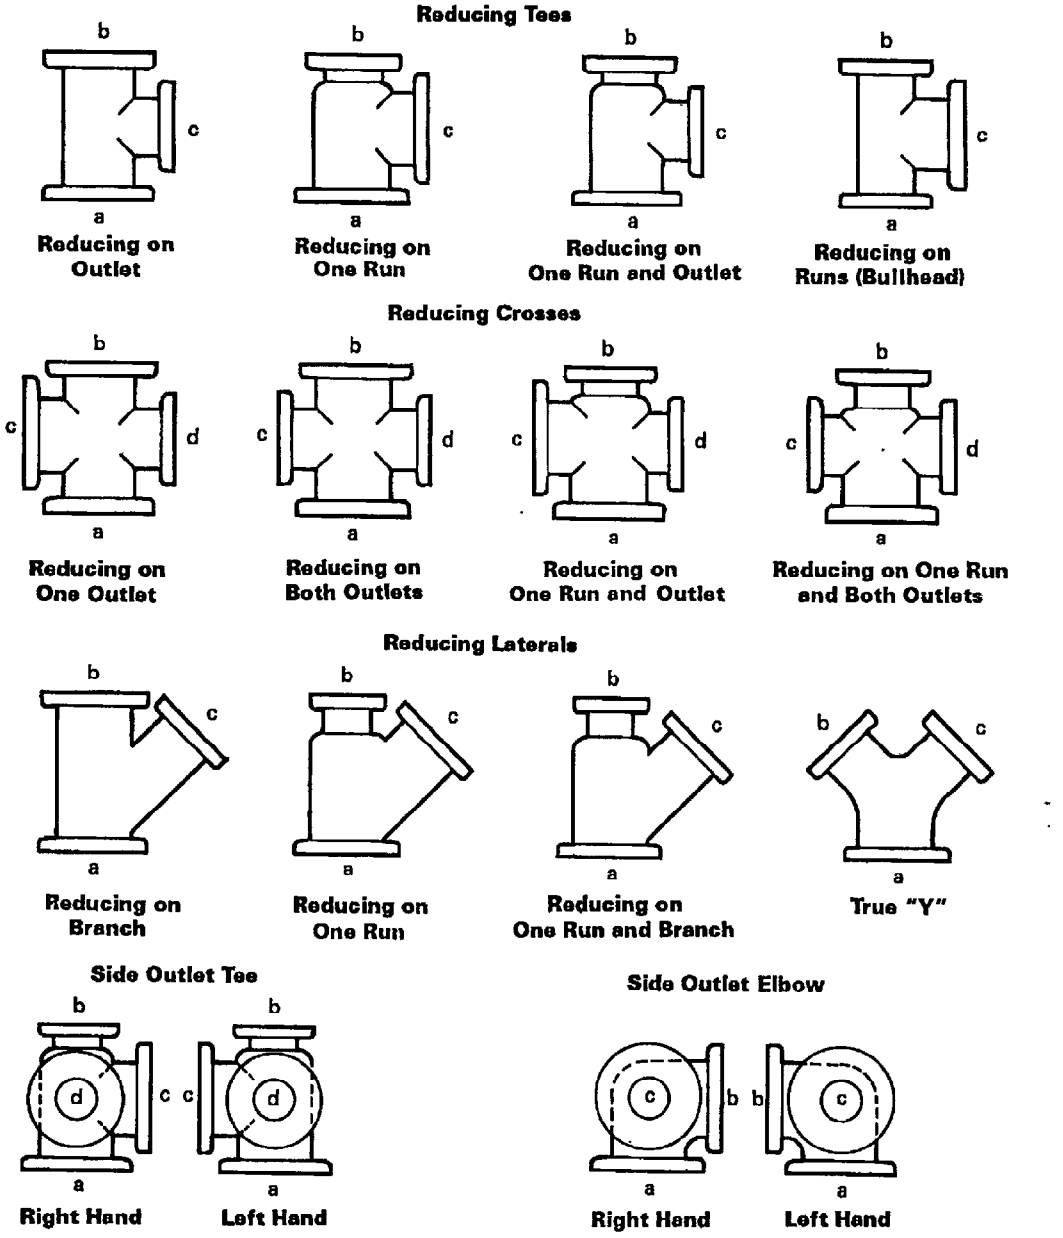

FIG. 1 METHOD OF DESIGNATING OUTLETS OF REDUCING FITTINGS

GENERAL NOTES:

(a) In designating the openings of reducing fittings they should be read in the order indicated by the sequence of the letters a, b, c, and d. In designating the outlets of side outlet reducing fittings, the side outlet is named last and in the case of the cross which is not shown, the side outlet is designated by the letter e.

(b) The largest opening establishes the basic size of a reducing fitting. The largest opening is named first, except for bullhead tees which are reducing on both runs and for double branch elbows where both branches are reducing, the outlet is the largest opening and named last in both cases. (Double branch elbows are not included in this Standard.)

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:44 2005

5.3.1 Alloy C83600. Castings shall meet the requirements of ASTM B62.

5.3.2 Alloy C92200. Castings shall meet the requirements of ASTM B61.

5.4 Bolting

Bolting materials recommended for use with copper alloy flanges and flanged fittings are described in the following paragraphs.

5.4.1 Steel Bolting. Bolting material having allowable stresses not less than those for ASTM A193 Gr B7 are listed as high strength in Table 1B in ASME/ANSI B16.5. These and other materials of comparable strength may be used in any flanged joint. Carbon steel bolting conforming to ASTM A307 shall not be used below −20°F nor above 400°F and is limited for use with Class 150 and 300.

5.4.2 Nonferrous Boltings. The following nonferrous materials may be used for Class 150 and 300 within the temperature limitation stated. Other bolting materials that have at least a 30 ksi specified minimum yield strength may be used when permitted by the applicable code or regulations.

ASTM Spec.	Alloy UNS No.	Condition	Notes
B98	C65100	Half Hard	(1)
	C65500	Half Hard	(1)
	C66100	Half Hard	(1)
B150	C61400		(2)
	C63000		(2)
	C64200		(2)
B164	N04400	Hot Finish	
	N04400	Cold Drawn	(2)
	N04400	Cold Drawn, Stress Relieved	(2)
	N04400	Cold Drawn, Stress Equalized	(2)
	N04405	Hot Finish	
	N04405	Cold Drawn	(2)

NOTES:
(1) Maximum operating temperature 350°F
(2) Maximum operating temperature 550°F

5.5 Gaskets

Materials for gaskets are described in Annex E of ASME/ANSI B16.5. The user is responsible for selection of gasket materials which will withstand the expected bolt loading without injurious crushing and which are suitable for the service conditions. Particular attention needs to be given to gasket selection if the user elects to use a hydrostatic test pressure that exceeds the test pressure specified in para. 2.5.

5.6 Materials Selection

Criteria for the selection of materials are not within the scope of this Standard. The possibility of material deterioration in service should be considered by the user. A discussion of precautionary considerations can be found in Appendix F of ASME B31.3.

6 FLANGE DIMENSIONS

6.1 Flange dimensions are dependent upon the flange casting material.

6.1.1 Alloys C83600 and C92200. The flange dimensions shall be in accordance with Tables 3 and 5 with alternative facings as permitted in para. 6.2.

6.1.2 Alloy C95200. The flange dimensions shall be in accordance with the dimensional requirements of ASME/ANSI B16.5.

6.2 End Flange Facings

Class 150 and 300 blind and companion flanges are regularly furnished with a flat face. Class 400 and higher companion flanges are regularly furnished with a 0.25 in. raised face, with the exception of the small male face (on end of pipe) and the small female face (on end of pipe). When using straight pipe threads, any of the flange pipe threads shown in ASME/ANSI B16.5 may be used with copper alloy flanges. When flanges of alloy C83600 or alloy C92200 are furnished with one of the alternative ASME/ANSI B16.5 facings, any required raised face dimension shall be in addition to the basic flange thickness, "C", of Tables 3 and 5.

6.3 Threaded Flanges

Threaded flanges shall have a taper pipe thread in accordance with ANSI/ASME B1.20.1. Variations in alignment of the thread with the axis of the flange shall not exceed 0.06 in./ft.

6.4 Thread Chamfer

All flanges of alloy C83600 and C92200 shall be made without a counterbore. The threads shall be

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:44 2005

chamfered approximately to the major diameter of the thread at the pipe end of the flange at an angle approximately 45 deg. with the axis of the thread. The chamfer shall be concentric with the thread and shall be included in the measurement of the thread length.

6.5 Thread Length

The length of the thread shall include the chamfer.

6.6 Thread Gaging

The gaging notch of the thread gage shall come flush with the bottom of the chamfer in all threaded flanges, and shall be considered as being the intersection of the chamfer cone and the pitch cone of the thread. This depth of chamfer is approximately equal to one-half the pitch of the thread. The maximum allowable thread variation is one turn large or small from the gaging notch.

6.7 Threaded Flange Assembly

External pipe threads used with higher pressure flanges must be longer than normal to bring the end of the pipe close to the face of the flange when parts are assembled by power equipment. The additional length and number of turns are shown in Annex A of ASME/ANSI B16.5 for ANSI/ASME B1.20.1 threads.

6.8 Integral Flanges

When flanges are integral with fittings or valves, pairs of bolt holes shall straddle the center line.

6.9 Spot and Back Facing

Flanges and flanged fittings covered by this Standard shall have bearing surfaces for bolting which shall be parallel to the flange face within 1 deg. Any spot or back facing shall not reduce the flange thickness, "C," below the dimension required by para. 6.1. The spot facing diameter shall be in accordance with MSS-SP-9. When cutting into the hub of flanges or flanged fittings with back facing tools, the intersection shall have a radius of not less than 0.06 in.

7 FITTING DIMENSIONS

7.1 Center-to-Face Dimensions

7.1.1 Side Outlet Fittings. Side outlet elbows and side outlet tees shall have all openings on intersecting center lines.

7.1.2 Elbows

(a) The center-to-face dimensions for straight size 90 deg. elbows, 90 deg. long radius elbows, 45 deg. elbows, and side outlet 90 deg. elbows are shown in Tables 4 and 6.

(b) Reducing 90 deg. elbows and reducing side outlet 90 deg. elbows shall have the same center-to-face dimensions as straight size fittings shown in Tables 4 and 6, corresponding to the size of the largest opening.

(c) Special degree elbows ranging from 1 to 45 deg., inclusive, shall have the same center-to-face dimensions given for 45 deg. elbows and those over 45 deg. and up to 90 deg., inclusive, shall have the same center-to-face dimensions given for 90 deg. elbows. The angle designation of an elbow is its deflection from straight line flow and is the angle between the flange faces.

7.1.3 Tees, Crosses, and Laterals

(a) The center-to-face dimensions for straight size tees, with or without side outlet, crosses, and laterals are shown in Tables 4 and 6.

(b) Reducing tees, with or without side outlet, reducing crosses, and reducing laterals shall have the same center-to-face dimensions as straight size fittings shown in Tables 4 and 6, corresponding to the size of the largest opening. Tees, crosses, and laterals, reducing on the run only, shall have the same center-to-face dimensions as straight size fittings shown in Tables 4 and 6, corresponding to the size of the largest opening.

(c) Tees reducing on both runs are generally known as bullhead tees and have the same center-to-face dimensions as straight size fittings corresponding to the size of the outlet.

7.1.4 True Ys. Center-to-face dimensions for straight size true Ys are shown in Tables 4 and 6. Reducing sizes are considered special and should be made to suit conditions.

7.1.5 Reducers and Eccentric Reducers. The face-to-face dimensions for all combinations of reducers and eccentric reducers shall be the same as given in Tables 4 and 6 for the larger opening.

7.1.6 Interchangeability. Class 150 flanged fittings in NPS 1 and larger have a bolting pattern that is dimensionally interchangeable with Class 125 Cast Iron Flanged Fittings (ASME/ANSI B16.1), Class

Copyright by the American Society Of Mechanical Engineers

150 Steel Flanged Fittings (ASME/ANSI B16.5), and Class 150 Ductile Iron Flanged Fittings (ASME/ANSI B16.42). Class 300 flanged fittings in NPS 1 and larger have a bolting pattern that is dimensionally interchangeable with Class 250 Cast Iron Flanged Fittings (ASME/ANSI B16.1), Class 300 Steel Flanged Fittings (ASME/ANSI B16.5), and Class 300 Ductile Iron Flanged Fittings (ASME/ANSI B16.42).

7.2 Wall Thickness

For inspection purposes, the minimum wall thickness, "t," of flanged fittings at the time of manufacture shall be as shown in Tables 4 and 6, except as provided in para. 9.1. Additional metal thickness needed to withstand assembly stresses, shapes other than circular, and stress concentrations must be determined by the manufacturer. In particular, 45 deg. laterals, true Ys, and crosses may require additional reinforcement to compensate for inherent weaknesses in these shapes.

8 BOLTING, NUTS, AND GASKETS

(a) For carbon steel and nonferreous bolting smaller than three-quarter inch, ANSI Standard Square Heads, ANSI Standard Heavy Hex Heads (ANSI B18.2.1), or ANSI Standard Heavy Hex Nuts (ANSI B18.2.2) are recommended. For carbon steel and nonferrous bolting three-quarter inch and larger, ANSI Standard Heads, ANSI Standard Hex Heads (ANSI B18.2.1), ANSI Standard Hex Nuts, or ANSI Heavy Hex Nuts (ANSI B18.2.2) are recommended.

All bolting and nuts shall be threaded in accordance with ANSI Standard Unified Screw Threads (ANSI B1.1), Coarse Thread Series, Class 2A and Class 2B.

(b) Full faced gaskets extending to the flange edge as given in ANSI B16.21, are required for flat faced surfaces such as shown in Tables 3 and 5. Metallic gaskets shall not be used with flat faced flanges.

If bolting material is either carbon steel or nonferrous, compressed sheet gaskets that are less than 0.12 in. thick should not be used.

9 TOLERANCES[1]

9.1 Wall Thickness

Fittings with local areas having less than minimum wall thickness will be acceptable provided that:

(a) the area of subminimum thickness can be enclosed by a circle whose diameter is no greater than $0.35\sqrt{dt}$ where d is the inside diameter and t is the minimum wall thickness as shown in Tables 4 and 6;

(b) measured thickness is not less than $0.9t$;

(c) enclosure circles are separated from each other by an edge-to-edge distance of not less than $1.75\sqrt{dt}$.

9.2 Center-to-Face

The following tolerances shall be permitted on all center-to-contact surface dimensions of fittings:

Nominal Pipe Size	Plus or Minus
10 and smaller	0.03 in.
12	0.06 in.

Tolerances for contact surface-to-contact surface dimensions shall be twice those given above. The largest opening in the fitting governs the tolerance to be applied to all openings.

9.3 Facings

9.3.1 Outside Diameter, 0.25 in. raised face, 0.02 in.

9.4 Flange Thickness

Sizes NPS 12 and smaller — +0.12 in.
−zero

9.5 Counterbore, Threaded Flanges

Sizes NPS 10 and smaller — +0.03 in.
−zero
Sizes NPS 12 and larger — +0.06 in.
−zero

9.6 Drilling and Facing

9.6.1 Bolt Circle Diameter ±0.06 in.

9.6.2 Center-to-Center of adjacent bolt holes ±0.03 in.

10 TESTS

10.1 Flange Testing

Flanges are not required to be pressure tested.

[1]Unless otherwise stated, tolerances are equal, plus and minus.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:49:45 2005

10.2 Flanged Fitting Testing

Each flanged fitting shall be given a shell test in accordance with para. 10.2.1 or 10.2.2.

10.2.1 Class 150 fitting made from alloys C83600 or C92200 in sizes ½ in. through 4 in. may be pneumatically tested at 80 psi (minimum) while under water for a minimum of 2 minutes. No visible leakage is permitted through the pressure boundary wall.

10.2.2 Hydrostatic Shell Test. The hydrostatic shell test for flanged fittings shall be no less than 1.5 times the 100°F rating rounded off to the next higher 25 psi increment. Test pressures are shown in Tables 1 and 2.

(a) The test shall be made with water, which may contain a corrosion inhibitor, with kerosene, or with another suitable fluid, provided its viscosity is no greater than that of water, at a test temperature not above 125°F.

(b) The test duration shall be a minimum of 1 minute for fittings NPS 2 and smaller, 2 minutes for fittings NPS 2½ to 8, and 3 minutes for NPS 10 and 12.

(c) No visible leakage is permitted through the pressure boundary wall.

The following is a list of standards and specifications referenced in this Standard showing the year of approval.

ASME Publications (Approved as American National Standards)

ASME/ANSI B1.1-1989	Unified Inch Screw Threads (UN and UNR Thread Form)
ASME/ANSI B1.20.1-1983	Pipe Threads, General Purpose (Inch)
ASME/ANSI B16.1-1989	Cast Iron Pipe Flanges and Flanged Fittings, Class 25, 125, 250 and 800
ASME/ANSI B16.5-1988	Steel Pipe Flanges and Flanges Fittings, Including Ratings for Class 150, 300, 400, 600, 900, 1500 and 2500
ANSI B16.21-1978	Nonmetallic Flat Gaskets for Pipe Flanges
ANSI B18.2.1-1981	Square and Hex Bolts and Screws
ANSI B18.2.2-1982	Square and Hex Nuts
ANSI B31.1-1989	Power Piping
ASME/ANSI B31.5-1989	Refrigeration Piping
ASME BPV-I-1989	Power Boilers

ASTM Publications

ASTM A 193-90	Specification for Alloy-Steel and Stainless Steel Bolting Materials for High-Temperature Service
ASTM A 307-90	Specification for Carbon Steel Externally and Internally Threaded Standard Fasteners
ASTM B 61-86	Specification for Steam or Valve Bronze Castings
ASTM B 62-86	Specification for Composition Bronze or Ounce Metal Castings
ASTM B 98-84	Specification for Copper-Silicon Alloy Rod, Bar and Shapes
ASTM B 150-86	Specification for Aluminum Bronze Rod, Bar and Shapes
ASTM B 164-84	Specification for Nickel-Copper Alloy Rod and Bar

Date of Issuance: May 30, 1997

The 1997 edition of this Standard is being issued with an automatic addenda subscription service. The use of an addenda allows revisions made in response to public review comments or committee actions to be published as necessary; revisions published in addenda will become effective 6 months after the Date of Issuance of the addenda. The next edition of this Standard is scheduled for publication in 2002.

ASME issues written replies to inquiries concerning interpretations of technical aspects of this Standard. The interpretations will be included with the above addenda service. Interpretations are not part of the addenda to the Standard.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Consensus Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that the determination of the validity of any such patent rights, and the risk of the infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

FOREWORD

(This Foreword is not part of ASME B16.25–1997.)

In July 1953, the American Welding Society presented a proposal on Welding End Preparation to Sectional Committee B16 of the American Standards Association (ASA), with the recommendation that it be considered as a candidate American Standard. The proposal was expanded to include welding preparation for flanges and valves covered by ASA B16.5, Steel Pipe Flanges and Flanged Fittings, and for fittings covered by ASA B16.9, Buttwelding Fittings. Consideration was also given to Pipe Fabrication Institute Standard ES-1.

The third draft reviewed by Subcommittee 3, Subgroup 6 (now Subcommittee F) of the B16 Sectional Committee was forwarded to the Committee, to the cosponsor organizations, and then to ASA for approval. Final approval was given on September 14, 1955, with the designation ASA B16.25–1955.

Revisions were developed as need for clarification and improvement became known, and were approved as ASA B16.25–1958 and ASA B16.25–1964. After ASA reorganized as the American National Standards Institute (ANSI) and the Sectional Committee became American National Standards Committee B16, a further revision was approved as ANSI B16.25–1972.

Subcommittee F immediately began work on a major expansion and updating of the standard, adding illustrations and requirements for welding end configurations applicable to a number of specific circumstances, including cast steel and alloy valves. When a draft had been developed that overcame the many problems and conflicting demands, the Standards Committee, cosecretariat organizations, and ANSI concurred in approval of ANSI B16.25–1979 on July 18, 1979.

In 1982, American National Standards Committee B16 was reorganized as an ASME Committee operating under procedures accredited by ANSI. In the 1986 edition, inch dimensions were established as the standard and numerous changes in text and format were made. Notes for illustrations were also clarified. Following approval by the Standards Committee and ASME, approval as American National Standard was given by ANSI on October 8, 1986, with the new designation ASME/ANSI B16.25–1986.

In 1992, the subcommittee revised the requirements for the preparation of the inside diameter of welding end. The references in Annex B were also updated. After public review and approval by ASME, this edition was approved by ANSI on October 26, 1992, with the new designation ASME B16.25–1992.

In this 1997 Edition, metric dimensions were added as an independent but equal standard to the inch units. An Annex was also added to reference quality system requirements. Following approval by the Standards Committee and ASME, this revision to the 1992 edition of B16.25 was approved as an American National Standard by ANSI on April 17, 1997, with the new designation ASME B16.25–1997.

Requests for interpretation or suggestions for revision should be sent to the Secretary, B16 Committee, The American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017.

BUTTWELDING ENDS

1 SCOPE

1.1 General

This Standard covers the preparation of buttwelding ends of piping components to be joined into a piping system by welding. It includes requirements for welding bevels, for external and internal shaping of heavy-wall components, and for preparation of internal ends (including dimensions and tolerances). Coverage includes preparation for joints with the following:

(a) no backing rings;

(b) split or noncontinuous backing rings;

(c) solid or continuous backing rings;

(d) consumable insert rings;

(e) gas tungsten arc welding (GTAW) of the root pass.

Details of preparation for any backing ring must be specified in ordering the component.

1.2 Application

This Standard applies to any metallic materials for which a welding procedure can be satisfactorily qualified, but does not prescribe specific welding processes or procedures. Unless otherwise specified by the purchaser, it does not apply to welding ends conforming to ASME B16.5, B16.9, or B16.28.

1.3 Standard Units

The values stated in either metric or inch units are to be regarded separately as standard. Within the text, the inch units are shown in parentheses. The values stated in each system are not exact equivalents; therefore each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the Standard.

1.4 Referenced Standards

Standards and specifications adopted by reference in this Standard are shown in Annex C, which is part of this Standard. It is not considered practical to identify the specific edition of each standard and specification in the individual references; instead the specific edition is identified in Annex C. An end preparation made in conformance to this Standard in all other respects, will be considered to be in conformance to the Standard even though the edition reference may be changed in a subsequent addendum to or revision of the Standard.

1.5 Quality Systems

Nonmandatory requirements relating to the manufacturer's Quality System Program are described in Annex B.

1.6 Convention

For the purpose of determining conformance with this Standard, the convention for fixing significant digits where limits, maximum or minimum values, are specified shall be "rounding off" as defined in ASTM Practice E 29. This requires that an observed or calculated value shall be rounded off to the nearest unit in the last right-hand digit used for expressing the limit. Decimal values and tolerances do not imply a particular method of measurement.

2 TRANSITION CONTOURS

Figure 1 delineates the maximum envelope in which transitions from welding bevel to the outer surface of the component and from the root face to the inner surface of the component must lie. Except as specified in Note (5) to Fig. 1 and as otherwise specified by the purchaser, the exact contour within this envelope is the manufacturer's option, providing it maintains the specified minimum wall thickness, has no slopes steeper than those indicated for the respective regions, and includes the proper surface for backing rings if specified.

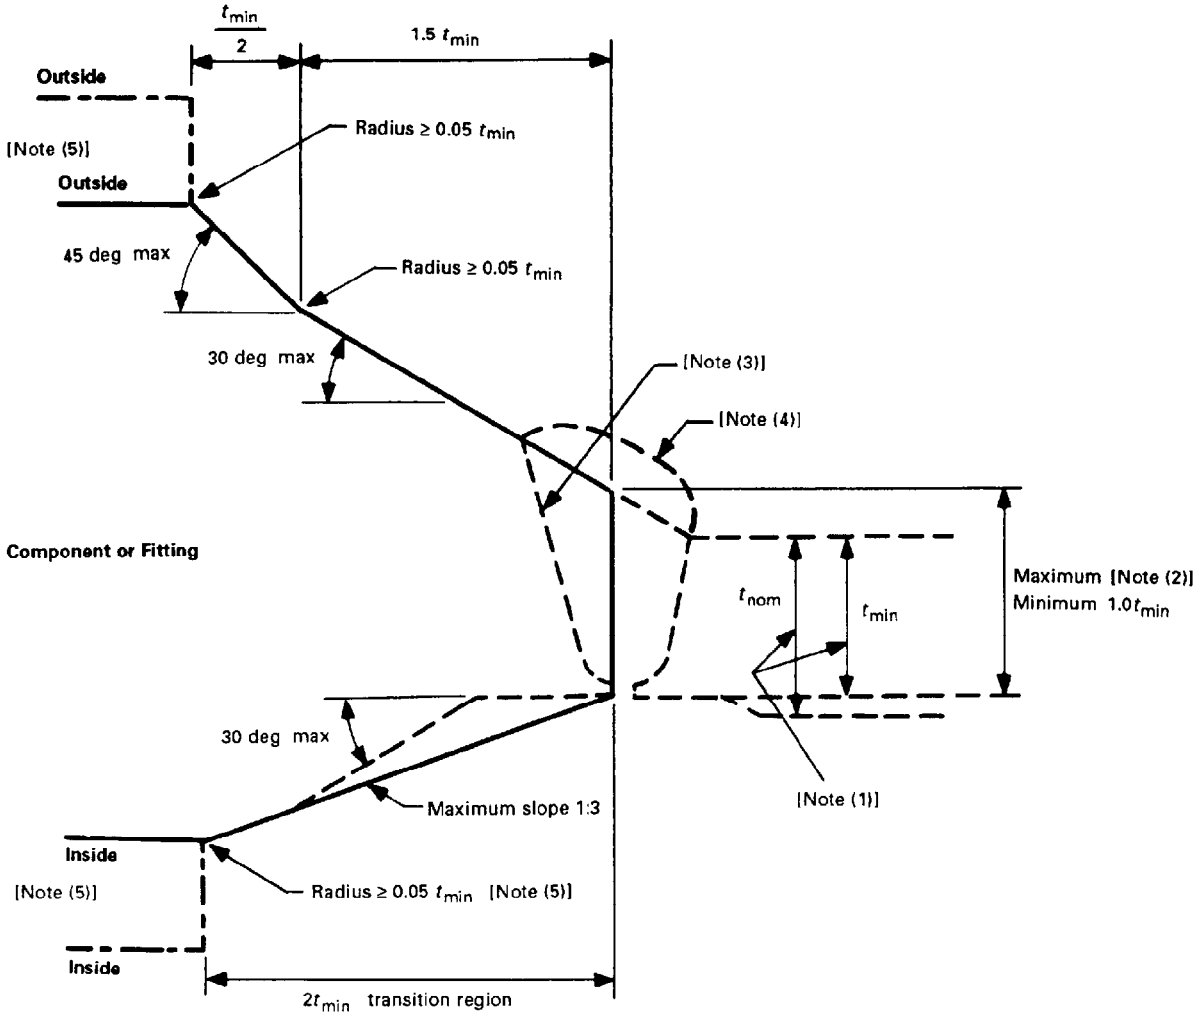
3 WELDING BEVEL DESIGN

3.1 Bevels for Other Than GTAW Root Pass

(a) Components having nominal wall thicknesses of 3 mm (0.12 in.) and less shall have ends cut square or slightly chamfered.

(b) Components having nominal wall thicknesses over 3 mm (0.12 in.) to 22 mm (0.88 in.) inclusive shall have single angle bevels as illustrated in Fig. 2.

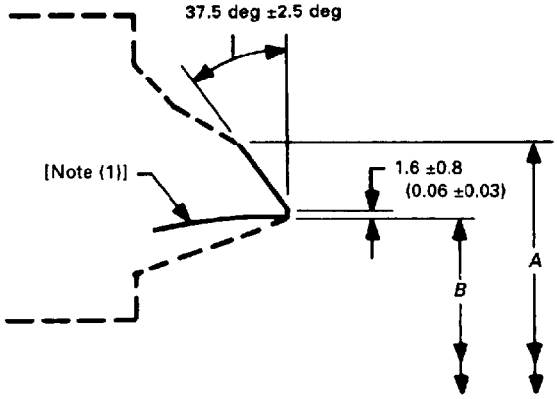
Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:21 2005



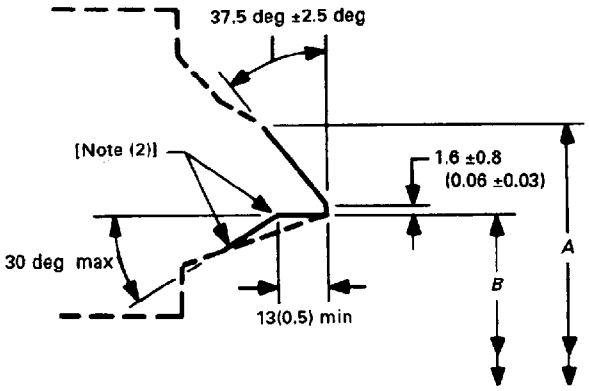
NOTES:
(1) The value of t_{min} is whichever of the following is applicable:
  (a) the minimum ordered wall thickness of the pipe;
  (b) 0.875 times the nominal wall thickness of pipe ordered to a pipe schedule wall thickness that has an under-tolerance of 12.5%;
  (c) the minimum ordered wall thickness of the cylindrical welding end of a component or fitting (or the thinner of the two) when the joint is between two components.
(2) The maximum thickness at the end of the component is:
  (a) the greater of t_{min} + 4 mm (0.16 in.) or 1.15t_{min} when ordered on a minimum wall basis;
  (b) the greater of t_{min} + 4 mm (0.16 in.) or 1.10t_{nom} when ordered on a nominal wall basis.
(3) Weld bevel shown is for illustration only.
(4) The weld reinforcement permitted by applicable code may lie outside the maximum envelope.
(5) Where transitions using maximum slope do not intersect inside or outside surface, as shown by phantom outlines, maximum slopes shown or alternate radii shall be used.

FIG. 1 MAXIMUM ENVELOPE FOR WELDING END TRANSITIONS

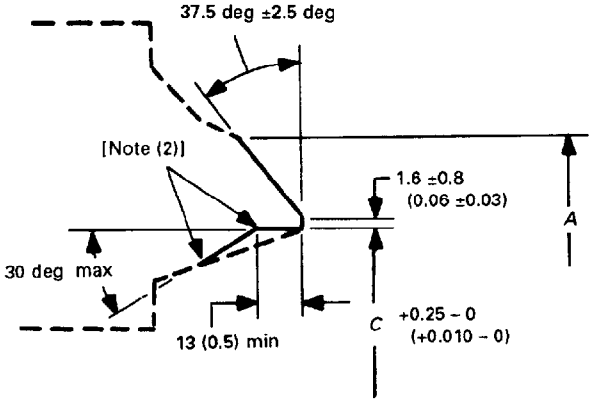
Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:21 2005



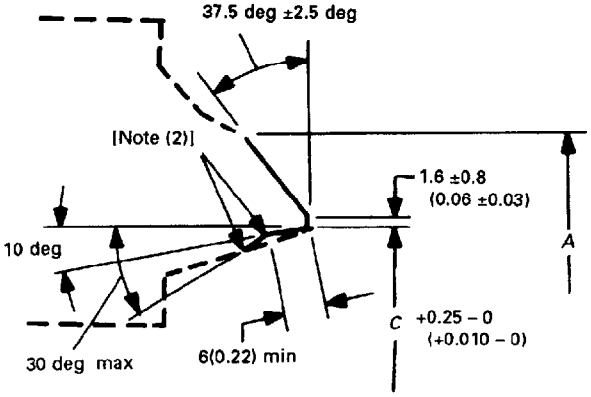
(a) Welding End Detail for Joint Without Backing Ring



(b) Welding End Detail for Joint Using Split Rectangular Backing Ring



(c) Welding End Detail for Joint Using Continuous Rectangular Backing Ring



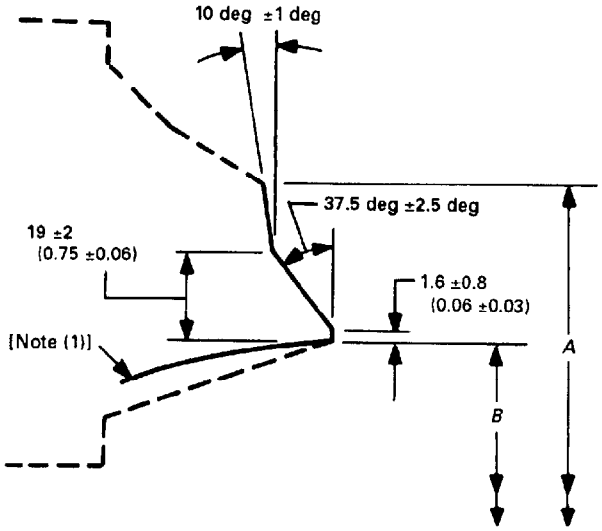
(d) Welding End Detail for Joint Using Continuous Tapered Backing Ring

GENERAL NOTES:
(a) Broken lines denote maximum envelope for transitions from welding bevel and root face into body of component. See Fig. 1 for details.
(b) See Section 5 for tolerances other than those given in these sketches.
(c) Purchase order must specify contour of any backing ring to be used.
(d) Linear dimensions are in millimeters with inch values in parentheses.

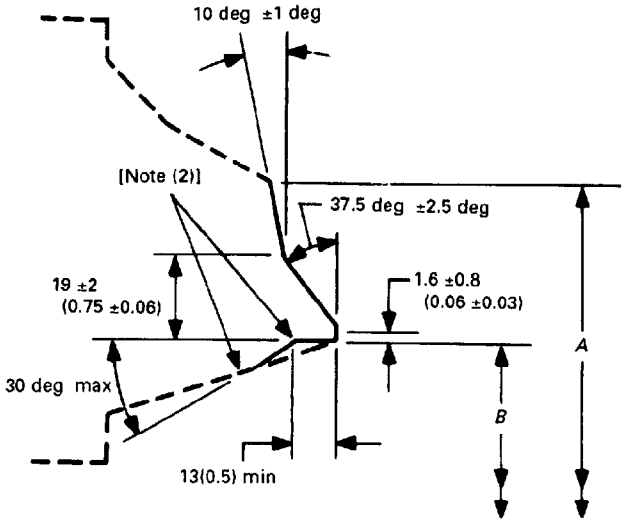
NOTES:
(1) Internal surface may be as-formed or machined for dimension *B* at root face. Contour within the envelope shall be in accordance with Section 2.
(2) Intersections should be slightly rounded.

FIG. 2 WELD BEVELS FOR WALL THICKNESS NOT OVER 22 mm (0.88 in.)

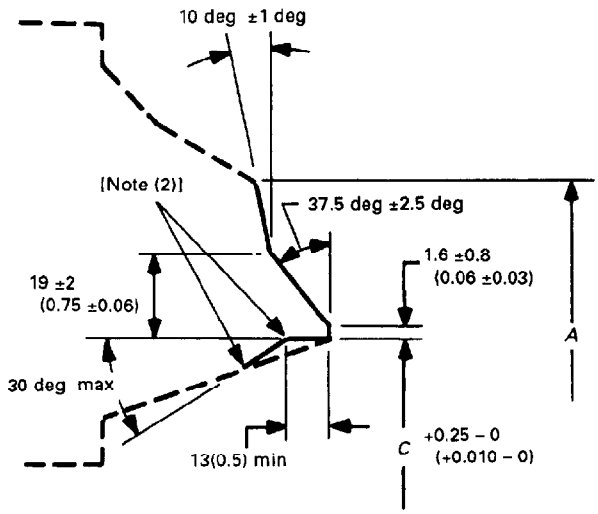
Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:21 2005



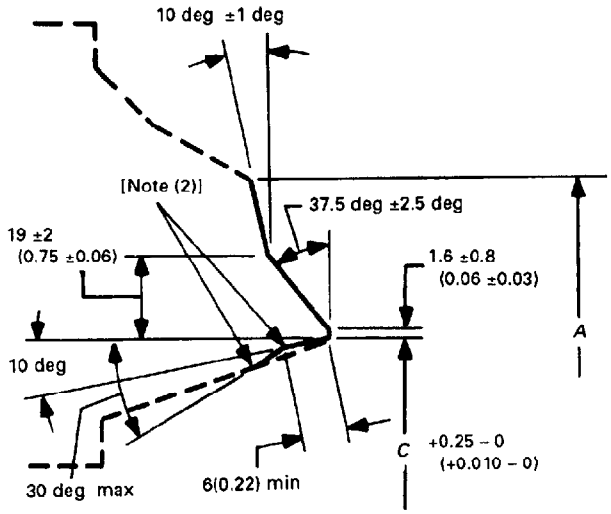
(a) Welding End Detail for Joint Without Backing Ring



(b) Welding End Detail for Joint Using Split Rectangular Backing Ring



(c) Welding End Detail for Joint Using Continuous Rectangular Backing Ring



(d) Welding End Detail for Joint Using Continuous Tapered Backing Ring

GENERAL NOTES:
(a) Broken lines denote maximum envelope for transitions from welding groove and root face into body of components. See Fig. 1 for details.
(b) See Section 5 for tolerances other than those given in these sketches.
(c) Purchase order must specify contour of any backing ring to be used.
(d) Linear dimensions are in millimeters with inch values in parentheses.

NOTES:
(1) Internal surface may be as-formed or machined for dimension *B* at root face. Contour within the envelope shall be in accordance with Section 2.
(2) Intersections should be slightly rounded.

FIG. 3 WELD BEVEL DETAILS FOR WALL THICKNESS OVER 22 mm (0.88 in.)

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:21 2005

(c) Components having nominal wall thicknesses greater than 22 mm (0.88 in.) shall have compound angle bevels as illustrated in Fig. 3.

3.2 Bevels for GTAW Root Pass

(a) Components having nominal wall thicknesses of 3 mm (0.12 in.) and less shall have ends cut square or slightly chamfered.

(b) Components having nominal wall thicknesses over 3 mm (0.12 in.) to 10 mm (0.38 in.) inclusive shall have 37½ deg ± 2½ deg bevels or slightly concave bevels. See Fig. 4.

(c) Components having nominal wall thicknesses over 10 mm (0.38 in.) to 25 mm (1.0 in.) inclusive shall have bevels as shown in Fig. 5.

(d) Components having nominal wall thicknesses greater than 25 mm (1.0 in.) shall have bevels as shown in Fig. 6.

4 PREPARATION OF INSIDE DIAMETER OF WELDING END

4.1 General

Preparation of the inside diameter at the end of a component shall be in accordance with one of the following, as specified by the purchaser.

(a) Components to be welded without backing rings shall meet the requirements of the standard or specification for the component.

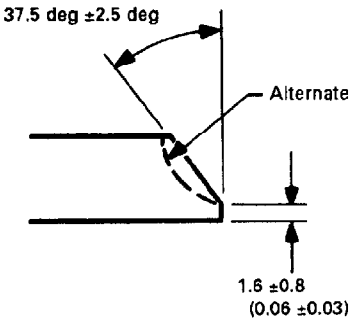
(b) Components to be welded using split or noncontinuous backing rings shall be contoured with a cylindrical surface at the end as shown in Fig. 2, sketch (b) and Fig. 3, sketch (b). If the backing ring contour is other than rectangular, details must be furnished by the purchaser.

(c) Components to be welded using solid or continuous backing rings shall be contoured with a cylindrical or tapered surface at the end as specified by the purchaser. End preparation is illustrated in Fig. 2, sketch (c) and Fig. 3, sketch (c) for rectangular ends and in Fig. 2, sketch (d) and Fig. 3, sketch (d) for tapered ends.

(d) Components to be welded using consumable insert rings or GTAW root pass shall be contoured with a cylindrical surface at the end as shown in Figs. 4, 5, and 6.

4.2 Dimension *C*

Values for dimension *C* shown in Fig. 2, sketches (c) and (d); Fig. 3, sketches (c) and (d); and Figs. 5 and 6 are tabulated in Table 1 for DN 65 through 900 (NPS 2½ through 36).



GENERAL NOTES:
(a) This detail applies for gas tungsten arc welding (GTAW) of the root pass where nominal wall thickness is over 3 mm (0.12 in.) to 10 mm (0.38 in.) inclusive.
(b) Linear dimensions are in millimeters with inch values in parentheses.

FIG. 4 WELD BEVEL DETAILS FOR GTAW ROOT PASS [Wall Thickness Over 3 mm (0.12 in.) to 10 mm (0.38 in.), Inclusive]

Dimensions for other sizes and/or wall thicknesses can be determined by the following formulas:

$$C = A - 0.79 - 1.75t - 0.25 \text{ mm}$$

$$(C = A - 0.031 - 1.75t - 0.010 \text{ in.})$$

where

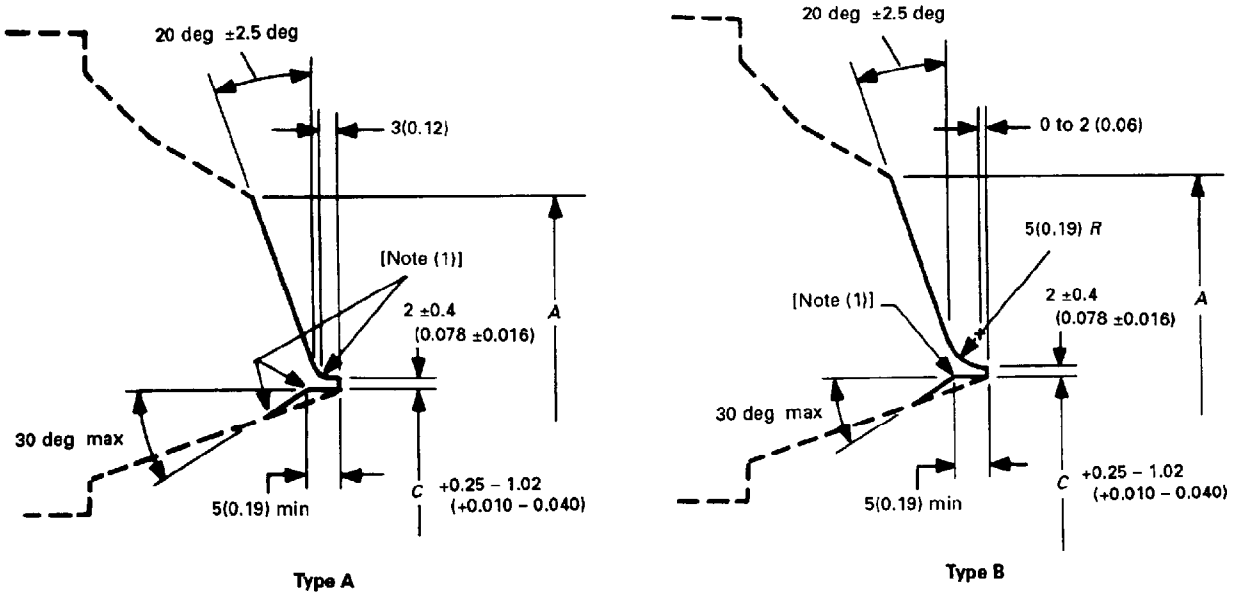
A = nominal O.D. of pipe (see column 3 in Tables 1 and A1, taken from ASME B36.10M)

0.79 (0.031) = minus tolerance on O.D. of pipe, mm (in.), as covered by ASTM specifications having the more restrictive requirements such as A 106, A 335, etc.

1.75 = minimal wall of 87½% of nominal wall (permitted by ASTM specification having the more restrictive requirements such as A 106, A 335, etc.) multiplied by 2 to convert into terms of diameter

t = nominal wall thickness of pipe, mm (in.)

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:21 2005



GENERAL NOTES:
(a) This detail applies for gas tungsten arc welding (GTAW) of the root pass where nominal wall thickness is over 10 mm (0.38 in.) to 25 mm (1.0 in.) inclusive.
(b) Broken lines denote maximum envelope for transitions from welding groove and land into body of component. See Fig. 1 for details.
(c) See Section 5 for tolerances other than those given in these sketches.
(d) Linear dimensions are in millimeters with inch values in parentheses.

NOTE:
(1) Inside corners should be slightly rounded.

FIG. 5 WELD BEVEL DETAILS FOR GTAW ROOT PASS [Wall Thickness Over 10 mm (0.38 in.) to 25 mm (1.0 in.), Inclusive]

0.25
(0.010) = plus machining tolerance on Bore *C*, mm (in.)

4.3 Exceptions

(a) For pipe or tubing varying from the ASTM A 106 and A 335 types, having different wall thickness and/or outside diameter tolerances (such as forged and bored pipe), the foregoing formulas may be inapplicable.

(b) For components in smaller sizes and lower schedule numbers, it may be necessary to deposit weld metal on the inside diameter or use thicker wall materials in order to machine the backing ring while maintaining required wall thickness. This condition may also arise when using material whose nominal dimensions indicate sufficient metal but whose actual inside diameter (I.D.), considering tolerances, is large enough to require additional metal.

5 TOLERANCES (See Figs. 2, 3, 5, and 6)

5.1 Dimension *B*

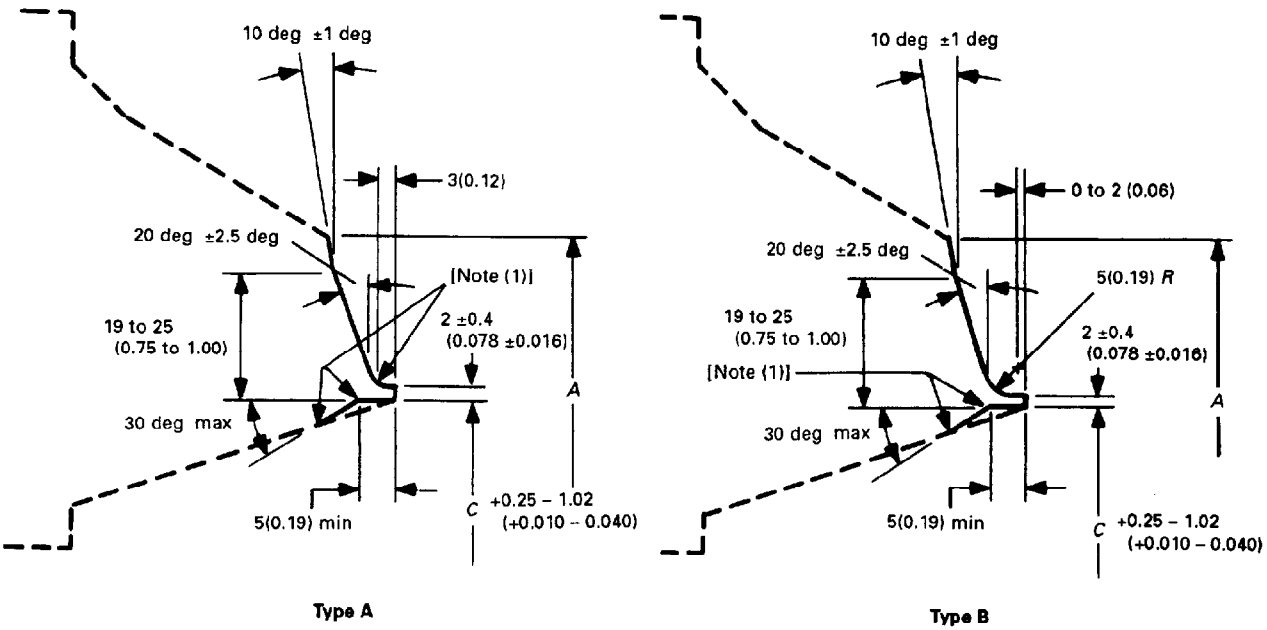
Values for the I.D. at the welding end [see dimension *B*, Fig. 2, sketches (a) and (b); and Fig. 3, sketches (a) and (b)] shall be as specified in the applicable standard or specification for the component.

5.2 Welding Bevels, Root Face, and Dimension *C*

Values of welding bevels, root face, and dimension *C* shall be as indicated in Figs. 2, 3, 4, 5, and 6.

Large diameter pipe and fittings with a relatively thin wall have a tendency to spring out-of-round after removal from the machining fixture. For this reason, the measured diameters may vary with orientation. A tolerance of +0.25 mm (+0.010 in.) shall apply to the average diameter.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:50:22 2005



GENERAL NOTES:
(a) This detail applies for gas tungsten arc welding (GTAW) of root pass where nominal wall thickness is greater than 25 mm (1.0 in.).
(b) Broken lines denote maximum envelope for transitions from welding groove and land into body of component. See Fig. 1 for details.
(c) See Section 5 for tolerances other than those given in these sketches.
(d) Linear dimensions are in millimeters with inch values in parentheses.

NOTE:
(1) Inside corners should be slightly rounded.

FIG. 6 WELD BEVEL DETAILS FOR GTAW ROOT PASS [Wall Thickness Over 25 mm (1.0 in.)]

5.3 Dimension *A*

Dimension *A* is the nominal outside diameter of the component at the welding end.

5.3.1 Valves (Column 4 of Tables 1 and A1)

Nominal Size	Tolerance
≤ DN 125 (NPS 5)	+2.4 mm (0.09 in.) −0.8 mm (0.03 in.)
≥ DN 150 (NPS 6)	+4.0 mm (0.16 in.) −0.8 mm (0.03 in.)

5.3.2 Other Components. Dimension *A* values for other components shall be as specified in the applicable standard or specification for the component.

5.4 Wall Thickness

The maximum thickness, t_{max}, at the end of the component is:

(a) greater of t_{min} + 4 mm (0.16 in.) or $1.15t_{min}$ when ordered on a minimum wall basis;

(b) greater of t_{min} + 4 mm (0.16 in.) or $1.10t_{nom}$ when ordered on a nominal wall basis (see Fig. 1).

The minimum thickness, t_{min}, shall be as specified in the applicable standard or specification for the component (see Figs. 2, 3, 5, and 6).

	40	914.4	927	876.5	880.02	19.05

GENERAL NOTES:
(a) Dimensions are in millimeters.
(b) See Section 5 for tolerances.

NOTES:
(1) Letter designations signify:
  (a) STD = standard wall thickness
  (b) XS = extra-strong wall thickness
  (c) XXS = double extra-strong wall thickness
(2) The diameters listed are not requirements. They are provided for the convenience of the user.
(3) Internal machining for continuous backing rings for sizes DN 50 and smaller is not contemplated. See para. 4.2 for *C* dimension for sizes not listed.

ANNEX A
INCH TABLE

(This Annex is an integral part of ASME B16.25 and is placed after the main text for convenience.)

This Annex provides a table of the standard inch dimensions for fittings.

	40	36.00	36.50	34.500	34.646	0.750

GENERAL NOTES:
(a) Dimensions are in inches.
(b) See Section 5 for tolerances.

NOTES:
(1) Letter designations signify:
  (a) STD = standard wall thickness
  (b) XS = extra-strong wall thickness
  (c) XXS = double extra-strong wall thickness
(2) The diameters listed are not requirements. They are provided for the convenience of the user.
(3) Internal machining for continuous backing rings for sizes NPS 2 and smaller is not contemplated. See para. 4.2 for *C* dimension for sizes not listed.

ANNEX B
QUALITY SYSTEM PROGRAM

(This is a nonmandatory part of ASME B16.25 and is included for information only.)

The products manufactured in accordance with ASME B16.25 shall be produced under a quality system program following the principles of an appropriate standard from the ISO 9000 series.[1] A determination of the need for registration and/or certification of the product manufacturer's quality system program by an independent organization shall be the responsibility of the manufacturer. The detailed documentation demonstrating program compliance shall be available to the purchaser at the manufacturer's facility. A written summary description of the program utilized by the product manufacturer shall be available to the purchaser upon request. The product manufacturer is defined as the entity whose name or trademark appears on the product in accordance with the marking or identification requirements of ASME B16.25.

[1] The series is also available from the American National Standards Institute (ANSI) and the American Society for Quality Control (ASQC) as American National Standards that are identified by a prefix "Q" replacing the prefix "ISO." Each standard of the series is listed under references.

Date of Issuance: November 30, 1994

The 1994 edition of this Standard is being issued with an automatic addenda subscription service. The use of an addenda allows revisions made in response to public review comments or committee actions to be published as necessary; revisions published in addenda will become effective 6 months after the Date of Issuance of the addenda. The next edition of this Standard is scheduled for publication in 1999.

ASME issues written replies to inquiries concerning interpretations of technical aspects of this Standard. The interpretations will be included with the above addenda service. Interpretations are not part of the addenda to the Standard.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Consensus Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

FOREWORD

(This Foreword is not part of ASME B16.28-1994.)

In 1921, the American Engineering Standards Committee, later American Standards Association (ASA), organized Sectional Committee B16 to unify and further develop national standards for pipe flanges and fittings (and, later, for valves, gaskets, and valve actuators). Cosponsors of the B16 Committee were the American Society of Mechanical Engineers (ASME), the Heating and Piping Contractors National Association [now Mechanical Contractors Association of America (MCAA)], and the Manufacturers Standardization Society of the Valve and Fittings Industry (MSS). Cosponsors were later designated as cosecretariat organizations.

In 1959, recognizing the increasing use of short radius buttwelding fittings not covered by ASA B16.9-1958, MSS developed Standard Practice SP-59. In 1963, this Standard was submitted to Subcommittee 6 (now Subcommittee F), the B16 group responsible for welded fittings, for consideration as a candidate American Standard. Following approval by the Committee, cosponsors, and ASA, the standard was published as ASA B16.28-1964.

In 1969, review of the document indicated that no changes were necessary. After reorganization of ASA, first as the United States of America Standards Institute (USASI), then as the American National Standards Institute (ANSI), with the Sectional Committee being redesignated as an American National Standards Committee, the reaffirmation was approved and published as ANSI B16.28-1964 (R1972). Subcommittee F then began a major revision to bring the standard up to date with current practice and usage. Metric dimensional equivalents were also added. Following Standards Committee, cosecretariat, and ANSI approval, the revision was published as ANSI B16.28-1978.

In 1982, American National Standards Committee B16 was reorganized as an ASME Committee operating under procedures accredited by ANSI. In the 1986 edition, the text was revised and inch dimensions were established as the standard. Following approval by the Standards Committee and ASME, approval as an American National Standard was given by ANSI on November 12, 1986, with the new designation ASME/ANSI B16.28-1986.

Commencing in 1991, the subcommittee reviewed the document and made a number of revisions. The 80% factor used in the computed proof test pressure in earlier B16.28 editions was changed to 100% in this 1994 edition. After public review and approval by ASME, this edition was approved by ANSI on October 10, 1994.

Requests for interpretation or suggestions for revision should be sent to the Secretary, B16 Committee, The American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017.

WROUGHT STEEL BUTTWELDING SHORT RADIUS ELBOWS AND RETURNS

1 SCOPE

1.1 General

This Standard covers ratings, overall dimensions, testing, tolerances, and markings for wrought carbon and alloy steel buttwelding short radius elbows and returns. The term *wrought* denotes fittings made of pipe, tubing, plate, or forgings.

1.2 Fabricated Fittings

Fabricated fittings employing intersection welds are not covered by this Standard. Design of such fittings is covered in the ASME B31, Code for Pressure Piping or the ASME Boiler and Pressure Vessel Code.

1.3 References

1.3.1 Referenced Standards. Standards and specifications adopted by reference in this Standard are shown in Annex B, which is part of this Standard. It is not considered practical to identify the specific edition of each standard and specification in the individual references. Instead the specific edition reference is identified in Annex B. A product made in conformance with a prior edition of reference standards and in all other respects conforming to this Standard will be considered to be in conformance.

1.3.2 Codes and Regulations. A fitting used under the jurisdiction of the ASME Boiler and Pressure Vessel Code, the ASME Code for Pressure Piping, or a governmental regulation is subject to any limitation of that code or regulation. This includes any maximum temperature limitation or rule governing the use of a material at low temperature.

1.4 Service Conditions

Criteria for selection of fitting types and materials suitable for particular fluid service are not within the scope of this Standard.

1.5 Welding

Installation welding requirements are outside the scope of this Standard. Installation welding shall be done in accordance with the applicable piping code or regulation covering the piping system into which the fittings are installed.

2 DESIGN AND PRESSURE RATINGS

2.1 Design of Fittings

The design of the fittings shall be established by mathematical method analysis contained in nationally recognized pressure vessel or piping codes or at the manufacturer's option by proof testing in accordance with Section 9 of this Standard. In order to meet design requirements, it is expected that some portion of formed fittings may have to be thicker than the pipe wall with which the fitting is intended to be used.

2.2 Basis of Ratings

The allowable pressure ratings for fittings designed in accordance with this Standard shall be as for straight seamless pipe of equivalent size and material [nominal pipe size (NPS), wall thickness or schedule number, and including a comparison of chemical composition and mechanical properties of the respective material specification].

2.3 Record Maintenance

Records of mathematical analysis and/or successful proof test data shall be available at the manufacturer's facility for inspection by the purchaser. Certified copies of this data shall be made available to the purchaser upon agreement with the manufacturer.

3 SIZE

The sizes of fittings in Tables 1, 2, and 3 are identified by the corresponding NPS as defined in ANSI/ASME B36.10M.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:51:07 2005

4 MARKING

4.1 Standard Marking (See Note)

Each fitting shall be permanently marked to show the following:

(a) manufacturer's name or trademark;

(b) material grade and class (ASTM or ASME grade symbol) and the heat number or manufacturer's heat identification;

(c) conformance to this Standard, designated by the prefix "WP" in the grade symbol marking;

(d) schedule number or nominal wall thickness designation;

(e) NPS.

NOTE: The pressure rating of the fitting is represented by the NPS, wall thickness (or schedule number), and material marked on the fitting. (See para. 2.2.)

4.2 Exceptions

Where the size of the fitting does not permit complete marking, the identification marks may be omitted in reverse of the order presented above.

4.3 Depth of Stamping

Where steel stamps are used, they shall be low stress and care should be taken so that the marking is not deep enough or sharp enough to cause cracks or to reduce the wall thickness of the fitting below the design minimum allowed.

5 MATERIAL

Wrought fittings covered by this Standard shall be in accordance with ASTM A 234, A 403, A 420, or the corresponding ASME Boiler and Pressure Vessel Code, Section II specification.

6 FITTINGS DIMENSIONS

This Standard provides for a fixed position for the welding ends with reference to either the center line of the fittings or the overall dimensions. Dimensional standards for these fittings are found in Tables 2, 3, A2, and A3.

The surface contour shall be essentially a segment of a torus that may be terminated in tangents.

7 END PREPARATION

Unless otherwise specified by the purchaser, welding ends shall be in accordance with ASME B16.25. For convenience, these welding ends are shown in Fig. 1 for fittings with wall thicknesses equal to that of the pipe to which they will be welded for use without a backing ring. Unless otherwise specified, fittings are furnished with welding ends for use without backing rings for the pipe wall thickness specified.

8 PRODUCTION TESTS

Hydrostatic testing of wrought fittings is not required by this Standard. All fittings shall be capable of withstanding, without leakage, a hydrostatic test pressure required by the applicable code for seamless pipe equivalent to the NPS, wall thickness, and material grade marked on the fitting.

9 DESIGN PROOF TESTS

9.1 Required Tests

Proof tests shall be made as set forth herein when the manufacturer chooses proof testing to qualify the fitting design. Unless otherwise agreed upon between manufacturer and purchaser, the only required type of proof test is a bursting strength test.

Proof tests conducted prior to the issuance of this edition of this Standard, which meet the requirements of this edition, are acceptable.

9.2 Test Assembly

9.2.1 Representative Fittings. Fittings that are representative of production and selected for test shall be identified as to material, grade, and lot, including heat treatment. They shall be inspected for dimensional compliance to this Standard.

9.2.2 Other Components. Straight seamless or welded pipe sections whose calculated bursting strength is at least as great as the proof test pressure as calculated in para. 9.3 shall be welded to each end of the fitting to be tested. Any internal misalignment greater than 0.06 in. (1.6 mm) shall be reduced by taper boring at a slope not over 1:3. The minimum length of pipe sections for closures shall be as follows:

(a) one pipe outside diameter for NPS 14 and smaller;

(b) one-half pipe outside diameter for NPS greater than 14.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:51:07 2005

9.3 Test Procedure and Acceptance Standard

Test fluid shall be water or other liquid used for hydrostatic testing. Hydrostatic pressure shall be applied to the assembly.

The proof test requirements are met when assembly withstands, without rupture, 105% of the computed proof test pressure defined below.

$$P = \frac{2St}{D}$$

where

P = computed proof test pressure
S = actual ultimate tensile strength of the test fitting determined on a specimen taken from the fitting or representative of the test fitting. The test fitting shall meet all requirements of one of the materials listed in para. 5.
t = nominal pipe wall thickness of the pipe that the fitting marking identifies
D = specified outside diameter of pipe that the fitting marking identifies

9.4 Applicability of Results

It is not necessary to conduct an individual test of fittings with all combinations of sizes, wall thicknesses, and materials. A proof test meeting the requirements of para. 9.3 on one representative fitting may represent other fittings of the same type to the extent described below.

9.4.1 Size Range. One test fitting may be used to qualify similarly proportioned fittings with an NPS range from one-half to twice that for the tested fitting.

9.4.2 Thickness Range. One test fitting may be used to qualify similarly proportioned fittings with t/D ranges from one-half to three times that for the tested fitting.

9.4.3 Material Grades. The pressure retaining capacity of a geometrically identical fitting made of various grades of steel will be directly proportional to the tensile properties of the various grades. Therefore, it is necessary to test only a single material grade in a representative fitting to prove the design of the fitting.

10 TOLERANCES

Tolerances for all fittings are shown in Tables 1 and A1, and are based on the nominal dimensions given in Tables 2, 3, A2, and A3.

For the purpose of determining conformance with this Standard, the convention for fixing significant digits where limits, maximum or minimum values, are specified, shall be "rounded off" as defined in ASTM E 29. This requires that an observed or calculated value shall be rounded off to the nearest unit in the last right-hand digit used for expressing the limit.

The listing of decimal tolerances does not imply the method of measurement.

Copyright by the American Society Of Mechanical Engineers

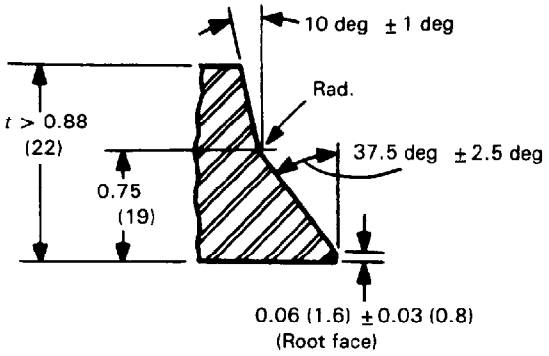
(a) Plain Bevel



(b) Compound Bevel

Nominal Wall Thickness *t*	End Preparation
Less than *x* [Note (1)]	Cut square or slightly chamfer, at manufacturer's option.
x to 0.88 incl. (22) [Note (1)]	Plain bevel as in sketch (a) above.
More than 0.88 (22)	Compound bevel as in sketch (b) above.

GENERAL NOTES:
(a) See ASME B16.25 for transitions from bevel and root face into body of fitting and backing ring preparations.
(b) Dimensions in parentheses are in millimeters.

NOTE:
(1) $x = 0.19$ (5) for carbon steel or ferritic alloy steel and 0.12 (3) for austenitic alloy steel

20 to 24	+0.25 −0.19	0.19		0.12	0.38	0.09	0.38	0.25	0.06

GENERAL NOTE: Dimensions are in inches. Tolerances are equal plus and minus except as noted.

NOTES:
(1) Out-of-round is the sum of absolute values of plus and minus tolerance.
(2) This tolerance may be exceeded in localized areas of formed fittings where increased wall thickness is required to meet design requirements of para. 2.1.
(3) The inside diameter and the nominal wall thicknesses at ends are to be specified by the purchaser. Wall thickness tolerance applies throughout the fitting.
(4) Unless otherwise specified by the purchaser, these tolerances apply to the nominal inside diameter, which equals the difference between the nominal outside diameter and twice the nominal wall thickness.

ANNEX A
METRIC (SI) TABLE

(This Annex is an integral part of ASME B16.28-1994, and is placed after the main text for convenience.)

The metric tolerances and dimensions shown in Tables A1, A2, and A3 are for information and reference. They are not exact equivalents of the dimensions in Tables 1, 2, and 3. If used by agreement between manufacturer and purchaser, complete dimensional interchangeability with standard components can not be assured. Use of a combination of standard and metric values is contrary to the intent of this Standard.

Date of Issuance: April 26, 1999

The 1998 edition of this Standard is being issued with an automatic addenda subscription service. The use of addenda allows revisions made in response to public review comments or committee actions to be published on a regular yearly basis; revisions published in addenda will become effective six months after the Date of Issuance of the addenda. The next edition of this Standard is scheduled for publication in 2003.

ASME issues written replies to inquiries concerning interpretations of technical aspects of this Standard. The interpretations will be included with the above addenda service.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment, which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assumes any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which precludes the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

FOREWORD

(This Foreword is not part of ASME B16.42-1998.)

In 1921, the American Engineering Standards Committee, later the American Standards Association (ASA), now the American National Standards Institute (ANSI), authorized the organization of a Sectional Committee on the Standardization of Pipe Flanges and Flanged Fittings, with the following organizations as joint sponsors: Heating, Piping, and Air Conditioning Contractors National Association (later the Mechanical Contractors Association of America, MCAA), Manufacturers Standardization Society of the Valves and Fittings Industry (MSS), and The American Society of Mechanical Engineers (ASME). Cast iron flanges and flanged fittings are within the scope of Subcommittee No. 1 (now Subcommittee A), with standards approved by ASA as early as 1928.

In 1957, piping components of ductile iron (also called nodular iron and, in Europe, spheroidal graphite iron) first appeared in the market. Controversy immediately developed over proper pressure-temperature ratings, and this was further aggravated by the use of casting patterns for both gray iron and carbon steel for producing the components.

Conflicting philosophies, which emerged from that controversy, thwarted efforts by MSS to develop standard practices in the early 1960s; the conflicts persisted during a study of ratings, starting in 1966 by American National Standards Committee B16 (as the Sectional Committee was called after reorganization of ASA as ANSI). The conflict continued to delay acceptance and approval of this Standard, which ultimately originated with a draft developed by MSS (taking advantage of earlier efforts) and submitted to Subcommittee A in 1977. Combining that draft with the rating basis developed in the B16 Committee, the first edition of this Standard was found acceptable and was approved by the Standards Committee, cosecretariat organizations, and ANSI, and was published with the designation ANSI B16.42-1979.

In 1982, American National Standards Committee B16 was reorganized as an ASME Committee operating under procedures accredited by ANSI. The 1981 edition of the Standard updated the referenced standards and specifications and established U.S. customary units as the standard. Following approval by the Standards Committee and ASME, ANSI granted its approval as an American National Standard on July 13, 1987, with the new designation ASME/ANSI B16.42-1987.

In the 1998 edition of ASME B16.42, Reference Standards are updated, a Quality System Program Annex is added, and several editorial revisions are made. Following approval by ASME B16 Subcommittee B and B16 Main Committee, ANSI approved this American National Standard on November 20, 1998.

Requests for interpretation or suggestions for revision should be sent to the Secretary, B16 Committee, The American Society of Mechanical Engineers, Three Park Avenue, New York, NY 10016-5990.

ASME B16 COMMITTEE
Standardization of Valves, Flanges, Fittings, Gaskets, and Valve Actuators

(The following is the roster of the Committee at the time of approval of this Standard.)

OFFICERS

W. N. McLean, *Chair*
H. R. Sonderegger, *Vice Chair*
P. A. Reddington, *Secretary*

COMMITTEE PERSONNEL

W. L. Ballis, Consultant, London, Ohio
R. W. Barnes, Anric Enterprises, Etobicoke, Ontario, Canada
R. R. Brodin, Fisher Controls International, Inc., Marshalltown, Iowa
M. A. Clark, Nibco, Inc., Elkhart, Indiana
A. Cohen, A. Cohen and Associates, Albuquerque, New Mexico
C. E. Floren, Mueller Co., Decatur, Illinois
D. R. Frikken, Solutia, Inc., St. Louis, Missouri
R. Henrich, Minnegasco, Inc., Golden Valley, Minnesota
J. C. Inch, Mueller Refrigeration Products Co., Hartsville, Tennessee
G. A. Jolly, Vogt Valve Co., Louisville, Kentucky
W. G. Knecht, BW/IP International, Inc., Williamsport, Pennsylvania
R. Koester, The William Powell Co., Cincinnati, Ohio
W. N. McLean, Newco Valves, Palos Park, Illinois
M. L. Nayyar, Bechtel Power Corp., Gaithersburg, Maryland
P. A. Reddington, The American Society of Mechanical Engineers, New York, New York
R. A. Schmidt, Trinity-Ladish Co., Russellville, Arkansas
H. R. Sonderegger, Grinnell Corp., Cranston, Rhode Island
W. M. Stephan, Flexitallic, Inc., Mount Laurel, New Jersey
T. F. Stroud, Ductile Iron Pipe Research Association, Birmingham, Alabama
M. D. Wasicek, ABS Americas, Houston, Texas
R. E. White, Richard E. White and Associates, South Bend, Indiana
D. A. Williams, Southern Company Services, Birmingham, Alabama
L. A. Willis, The Dow Chemical Co., Freeport, Texas
W. R. Worley, Union Carbide Corp., South Charleston, West Virginia

PERSONNEL OF SUBCOMMITTEE B — THREADED FITTINGS (Except Steel)

H. R. Sonderegger, *C & S Chair,* Grinnell Corp., Cranston, Rhode Island
B. P. Feder, *Secretary,* The American Society of Mechanical Engineers, New York, New York
K. Barron, Ward Manufacturing, Blossburg, Pennsylvania
M. A. Clark, Nibco, Inc., Elkhart, Indiana
A. Cohen, A. Cohen and Associates, Albuquerque, New Mexico
A. A. Knapp, Canadian Copper/Brass, Ontario, Canada
R. L. Larkin, American Darling Valve, Birmingham, Alabama
P. I. McGrath, Consultant, Birmingham, Alabama
W. N. McLean, Newco Valves, Palos Park, Illinois
J. K. Schultz, Conine Manufacturing Co.,Tyler, Texas

CORRESPONDENCE WITH B16 COMMITTEE

General. ASME Standards are developed and maintained with the intent to represent the consensus of concerned interests. As such, users of this Standard may interact with the Committee by requesting interpretations, proposing revisions, and attending Committee meetings. Correspondence should be addressed to:

Secretary, B16 Main Committee
The American Society of Mechanical Engineers
Three Park Avenue
New York, NY 10016-5990

Proposing Revisions. Revisions are made periodically to the Standard to incorporate changes that appear necessary or desirable, as demonstrated by the experience gained from the application of the Standard. Approved revisions will be published periodically.

The Committee welcomes proposals for revisions to this Standard. Such proposals should be as specific as possible, citing the paragraph number(s), the proposed wording, and a detailed description of the reasons for the proposal, including any pertinent documentation.

Interpretations. Upon request, the B16 Committee will render an interpretation of any requirement of the Standard. Interpretations can only be rendered in response to a written request sent to the Secretary of the B16 Main Committee.

The request for interpretation should be clear and unambiguous. It is further recommended that the inquirer submit his/her request in the following format:

Subject:	Cite the applicable paragraph number(s) and the topic of the inquiry.
Edition:	Cite the applicable edition of the Standard for which the interpretation is being requested.
Question:	Phrase the question as a request for an interpretation of a specific requirement suitable for general understanding and use, not as a request for an approval of a proprietary design or situation. The inquirer may also include any plans or drawings, which are necessary to explain the question; however, they should not contain proprietary names or information.

Requests that are not in this format will be rewritten in this format by the Committee prior to being answered, which may inadvertently change the intent of the original request.

ASME procedures provide for reconsideration of any interpretation when or if additional information that might affect an interpretation is available. Further, persons aggrieved by an interpretation may appeal to the cognizant ASME Committee or Subcommittee. ASME does not "approve," "certify," "rate," or "endorse" any item, construction, proprietary device, or activity.

Attending Committee Meetings. The B16 Main Committee regularly holds meetings, which are open to the public. Persons wishing to attend any meeting should contact the Secretary of the B16 Main Committee.

DUCTILE IRON PIPE FLANGES AND FLANGED FITTINGS
Classes 150 and 300

1 SCOPE

1.1 General

This Standard covers minimum requirements for Class 150 and 300 cast ductile iron pipe flanges and flanged fittings. The requirements covered are as follows:

(a) pressure-temperature ratings
(b) sizes and method of designating openings
(c) marking
(d) materials
(e) dimensions and tolerances
(f) bolts, nuts, and gaskets
(g) tests

1.2 Quality Systems

Requirements relating to the product manufacturers' Quality System Programs are described in Annex B.

1.3 References

1.3.1 Referenced Standards. Standards and specifications adopted by reference in this Standard are shown in Annex C, which is part of this Standard. It is not considered practical to identify the specific edition of each standard and specification in the individual references. Instead, the specific edition reference is identified in Annex C.

1.3.2 Codes and Regulations. A flange or flanged fitting used under the jurisdiction of the ASME Boiler and Pressure Vessel Code, the ASME Code for Pressure Piping, or a governmental regulation is subject to any limitation of that code or regulation. This includes any maximum temperature limitation, any rule governing the use of a material at low temperature, or provisions for operation at a pressure exceeding the pressure-temperature ratings in this Standard.

2 PRESSURE–TEMPERATURE RATINGS

2.1 General

Cast ductile iron pipe flanges and flanged fittings covered by this Standard shall be designated as one of the following: Class 150 or 300.

Except as provided in para. 2.5, ratings are maximum allowable nonshock working pressures, expressed as gage pressure, at the service temperature from –20°F to 650°F. Ratings in Table 1 are in U.S. customary units. For intermediate temperatures, linear interpolation is permitted. Methods for establishing pressure-temperature ratings are given in Annex A.

2.2 Ratings of Flanged Joints

Ratings in this Standard apply to flanged joints that conform to the limitations on bolting in para. 5.2 and on gaskets in para. 6.8, and which are made up in accordance with good practice for alignment and assembly. See also para. 2.4.

Use of the ratings for flanged joints not conforming to these limitations is the sole responsibility of the user. Requirements for alignment and assembly of joints are not given in this Standard.

If the two flanges in a flanged joint do not have the same pressure-temperature ratings, the rating of the joint at any temperature is the lower of the two flange ratings at that temperature.

2.3 Rating Temperature

The temperature shown for a corresponding pressure rating is the temperature of the pressure-containing shell of the flange or flanged fitting. In general, this temperature is the same as that of the contained fluid. Use of a pressure rating corresponding to a temperature other than that of the contained fluid is the responsibility of the user, subject to the requirements of the applicable code or regulation.

TABLE 1 PRESSURE-TEMPERATURE RATINGS, U.S. CUSTOMARY UNITS

	Working Pressure, psi gage	
Temperature, °F	Class 150	Class 300
-20 to 100	250	640
200	235	600
300	215	565
400	200	525
500	170	495
600	140	465
650	125	450

2.4 Temperature Considerations

Application of the ratings in this Standard to flanged joints at both high and low temperatures shall take into consideration the risk of leakage due to forces and moments developed in the connected piping or equipment. The following provisions are intended to minimize these risks.

2.4.1 Flange Attachment. Threaded flanges are not recommended for service above 500°F if severe thermal gradients or thermal cycling is involved.

2.4.2 High Temperature Service. When used above 400°F, Class 150 flanged joints may develop leakage unless care is taken to avoid imposing severe external loads and/or severe thermal gradients.

2.5 Variances From Ratings

Except as provided herein, ratings are the maximum allowable nonshock working pressure for the corresponding temperature.

2.5.1 Safety or Relief Valve Operation. Under conditions of safety valve, relief valve, or rupture disk operation, the pressure on a flange or flanged fitting may exceed the rated pressure at the pressure relieving temperature by no more than 10%. Such conditions are necessarily of short duration. Overpressure greater than the aforementioned under pressure-relieving conditions is the responsibility of the user, subject to the requirements of the applicable code or regulation.

2.5.2 Other Variances. Operating variations (transients) that subject a flange or flanged fitting to pressure in excess of the rated pressure at the corresponding temperature are the responsibility of the user, subject to the requirements of the applicable code or regulation.

2.5.3 System Hydrostatic Test. Flanged joints and flanged fittings may be subjected to system hydrostatic tests at a pressure not to exceed the hydrostatic shell test pressure specified in para. 8.3. Testing at any higher pressure is the responsibility of the user.

3 SIZE

3.1 Nominal Size

The size of a flange or flanged fitting covered by this Standard is its nominal pipe size (NPS). The diameter of a bolt is its nominal size. Use of nominal indicates that the stated size or dimension is only for designation, not measurement. The actual dimension may or may not be the nominal size and is subject to established tolerances.

3.2 Reducing Fitting Sizes

Reducing fittings shall be designated by the size of the openings in their proper sequence as indicated in the sketches, Fig. 1.

3.3 Reducing Flange Sizes

Reducing flanges shall be designated by the two nominal pipe sizes. See examples in Note (4), Table 2.

4 MARKING

Except as modified herein, flanges and flanged fittings shall be marked as required in MSS SP-25.

(a) Name. The manufacturer's name or trademark shall be applied.

(b) Material. The word "DUCTILE" ("D.I." where space does not permit "DUCTILE").

(c) Rating Class. Numerals shall be applied giving the pressure rating class for which the product is designed.

(d) Designation. The designation "B16" shall be applied, preferably located adjacent to the Class designation, to indicate conformance to this Standard.

(e) Temperature. No temperature markings are required on flanges and flanged fittings, but if marked, the temperature shall be shown with its corresponding tabulated pressure rating.

STD.ASME B16.42-ENGL 1998 ■ 0759670 0609004 231 ■

(f) Size. The nominal pipe size shall be given, but may be omitted from reducing flanges and reducing flanged fittings.

5 MATERIALS

5.1 Castings

Ductile iron castings covered by this Standard shall conform to ASTM A 395. The castings shall not be repaired by plugging, welding, brazing, or impregnation.

5.2 Bolting

Bolting listed in paras. 5.2.1 and 5.2.2 shall be used in flanged joints covered by this Standard. Bolting of other material may be used if permitted by the applicable code or governmental regulation.

5.2.1 High Strength Bolting. Bolting materials having allowable stresses not less than those for ASTM A 193 Grade B7 may be used with any flanged joint at all listed temperatures. The strength of the nut shall be not less than specified for ASTM A 194 Grade 2H.

5.2.2 Low Strength Bolting. Bolting materials with yield strength equivalent to ASTM A 307 Grade B are considered low strength and may be used for flanged joints at temperatures no greater than 400°F and only with gaskets described in para. 6.8.

5.2.3 Bolting to Cast Iron Flanges. When Class 150 ductile iron flanges are bolted to Class 125 cast iron flanges, or Class 300 ductile iron flanges are bolted to Class 250 cast iron flanges, it is recommended that low strength boltings be used within the limitations in para. 5.2.2. If high strength bolting is used, it is recommended that the mating flanges be flat faced and that full-faced gaskets (ASME B16.5, Fig. E1, Group Ia materials) extending to the O.D. of the flange be used.

5.3 Gaskets

Materials listed in Fig. E1 (ASME B16.5, Annex E) shall be used. The user is responsible for selection of gasket materials that will withstand the expected bolt load without injurious crushing and which are suitable for the service conditions.

For low strength bolting described in para. 5.2.2, only gaskets listed in Group Ia (ASME B16.5, Fig. E1) shall be used.

6 DIMENSIONS[1]

6.1 Center-to-Contact Surface and Center-to-End

6.1.1 Standard Fittings. Center-to-contact surface dimensions are shown in Tables 5 and 9.

6.1.2 Reducing Fittings. Center-to-contact surface or center-to-flange edge dimensions for all openings shall be the same as those of straight size fittings of the largest opening. The contact surface-to-contact surface dimensions for all combinations of reducers and eccentric reducers shall be as listed for the larger opening.

6.1.3 Side Outlet Fittings. Side outlet elbows, side outlet tees, and side outlet crosses shall have all openings on intersecting center lines, and the center-to-contact surface dimensions of the side outlet shall be the same as for the largest opening. Long radius elbows with side outlet shall have the side outlet on the radial center line of the elbow, and center-to-contact surface dimension of the side outlet shall be the same as for the regular 90 deg elbow of the largest opening.

6.1.4 Fittings With Bases. Dimensions of bases for base elbows and base tees are shown in Tables 6 and 10.

6.1.5 Special Degree Elbows. Special degree elbows ranging from 1 deg to 45 deg, inclusive, shall have the same center-to-contact surface dimensions as 45 deg elbows; those over 45 deg to 90 deg, inclusive, shall have the same center-to-contact surface dimensions as 90 deg elbows. The angle designation of an elbow is its deflection from straight line flow and is also the angle between the flange faces.

6.2 Facings

6.2.1 General. Class 150 fittings and companion flanges are regularly furnished flat or with a 0.06 in. raised face. Class 300 fittings and companion flanges are furnished with a 0.06 in. raised face. The raised face is included in the minimum flange thickness Q.

6.2.2 Facings of Blind Flanges. Blind flanges need not be faced in the center if, when this center part is raised, its diameter is at least 1 in. smaller than the inside diameter of the corresponding pressure class fittings, as given in the tables. When the center part

[1] Linear dimensions expressed in decimal fractions of an inch are actually common fractions rounded to the nearest two-place decimal.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:26 2005

is depressed, its diameter shall not be greater than the inside diameter of the corresponding pressure class fittings, as given in the tables. Machining of the depressed center is not required.

6.2.3 Flange Facing Finish. Contact faces shall be finished in accordance with MSS SP-6.

6.3 Flange Bolt Holes

Bolt holes are in multiples of four so that fittings may face in any quadrant. Pairs of bolt holes shall straddle the center lines.

6.4 Spot Facing

Spot facing is required on ductile iron flanges and flanges on fittings if the flange thickness at any point exceeds the required minimum thickness Q as given in Tables 4, 5, 8, and 9 by more than the following amounts.

Nominal Pipe Size	Excess Thickness, in., Max.
2–18	0.12
20–24	0.19

Diameter of spot facing, when required, shall be in accordance with MSS SP-9.

6.5 Reducing Flanges

6.5.1 Drilling, O.D., Thickness, and Facing Dimensions. Flange drilling, O.D., thickness, and facing are the same as those of the standard flange of the size from which the reduction is being made.

6.5.2 Threaded Flanges. The hub dimensions shall be at least as large as those of the standard flange of the size from which the reduction is being made. The hub may be larger or may be omitted, as detailed in Table 2.

6.6 Threads for Threaded Flanges

Threaded flanges shall have American National Standard Pipe Threads, General Purpose (Inch) conforming to ASME B1.20.1. The thread shall be concentric with the axis of the flange, and variations in alignment shall not exceed 0.06 in./ft (0.5%).

6.6.1 Class 150 Flanges. Class 150 flanges are made without a counterbore. The threads shall be chamfered approximately to the major diameter of the thread at the back of the flange at an angle of approximately 45 deg with the axis of the thread of afford easy entrance in making a joint and to protect the thread. The chamfer shall be concentric with the thread and shall be included in the measurement of the thread length.

6.6.2 Class 300 Flanges. Class 300 flanges may be made with a counterbore. The threads shall be chamfered to the diameter of the counterbore at the back of the flange at an angle of approximately 45 deg with the axis of the threads to afford easy entrance in making a joint. The counterbore and chamfer shall be concentric with the thread.

6.6.3 Length of Threads. The minimum length of effective thread in reducing flanges shall be at least equal to dimension T of the corresponding pressure class threaded flange as shown in the tables, but does not necessarily extend to the face of the flange. See Table 2 for reducing threaded flanges.

6.6.4 Threading Tolerances. The gaging notch of the working gage shall come flush with the bottom of the chamfer in all threaded flanges, and shall be considered as the intersection of the chamfer cone and the pitch cone of the thread. This depth of chamfer is approximately equal to one-half the pitch of the thread. The maximum allowable thread variation is one turn large or small from the gaging notch.

6.7 Stud Bolts, Bolts, and Nuts

6.7.1 Alloy Bolting. Alloy steel stud bolts, threaded at both ends or full length, or heavy hex bolts may be used. Heavy hex nuts shall be used with all alloy steel bolting.

6.7.2 Carbon Steel Bolting

(a) Bolts smaller than $\frac{3}{4}$ in. shall have square heads or heavy hex heads. Nuts shall be heavy hex.

(b) Bolts $\frac{3}{4}$ in. and larger shall have square heads or hex heads. Nuts shall be hex or heavy hex.

6.7.3 Bolt Dimensions. Dimensions of all bolts shall conform to ASME B18.2.1.

6.7.4 Nut Dimensions. Dimensions of all nuts shall conform to ASME B18.2.2.

6.7.5 Threading of Bolts

(a) Carbon steel bolting shall be threaded in accordance with ASME B1.1, coarse thread series, Class 2A for bolts and stud bolts, and Class 2B for nuts.

(b) Alloy steel bolting shall be threaded in accordance with ASME B1.1. Nominal diameters 1 in. and smaller

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:26 2005

shall be of the coarse thread series; nominal diameters $1\frac{1}{8}$ in. and larger shall be of the 8 thread series. Bolts, studs, and stud bolts shall have Class 2A dimensions; nuts shall have Class 2B dimensions.

6.8 Gaskets

Gaskets for Class 150 flat face flanges shall conform to the dimensions shown in ASME B16.21. For flanges with raised face, gaskets shall conform to limiting dimensions of ASME B16.5, Annex E.

6.9 Drains

6.9.1 Pipe Thread Tapping. Holes may be tapped in the wall of a fitting if the metal is thick enough to allow the effective thread length specified in MSS SP-45. Where thread length is insufficient or the tapped hole needs reinforcement, a boss shall be added.

6.9.2 Bosses. Where bosses are required, the diameters shall be as specified in MSS SP-45.

6.9.3 Designating Locations. The means of designating the locations of tapped holes or sockets for drains in fittings is shown in Fig. 2.

Each possible location is designated by a letter so that the desired locations for the various types of fittings may be specified without using further sketches or descriptions.

7 TOLERANCES

7.1 Wall Thickness

The wall thickness values for fittings listed in Tables 5 and 9 are minimum. Equipment shall be designed to produce greater nominal wall thickness so that manufacturing variances will not fall below these minimum values. See para. A1.2 in Annex A for the basis used to establish these values.

7.2 Center-to-Contact Surface and Contact Surface-to-Contact Surface

7.2.1 Center-to-Contact Surface

(a) Sizes NPS 10 and smaller, ±0.03 in.
(b) Sizes NPS 12 and larger, ±0.06 in.

7.2.2 Contact Surface-to-Contact Surface

(a) Sizes NPS 10 and smaller, ±0.06 in.
(b) Sizes NPS 12 and larger, ±0.12 in.

7.3 Facings

Outside diameter, 0.06 in. raised face, ±0.03 in.

7.4 Flange Thickness

(a) Sizes NPS 18 and smaller, +0.12 in. −0
(b) Sizes NPS 20 and larger, +0.19 in. −0

7.5 Bore of Flanges

7.5.1 Lapped Flanges

(a) Sizes NPS 10 and smaller, +0.03 in. −0
(b) Sizes NPS 12 and larger, +0.06 in. −0

7.5.2 Counterbore of Threaded Flanges

(a) Sizes NPS 10 and smaller, +0.03 in. −0
(b) Sizes NPS 12 and larger, +0.06 in. −0

7.6 Drilling and Facing

(a) Bolt circle diameter, +0.06 in.
(b) Center-to-center of adjacent bolt holes, ±0.03 in.
(c) Eccentricity between bolt circle diameter and machined facing diameters:
(1) Sizes NPS $2\frac{1}{2}$ and smaller, ±0.03 in.
(2) Sizes NPS 3 and larger, ±0.06 in.

8 TESTING

8.1 General

Flanged fittings shall be hydrostatically tested in accordance with para. 8.3.

8.2 Flange Testing

Flanges are not required to be hydrostatically tested. Flanges attached to (or integral with) piping, pressure vessels, or other equipment may be subject to system hydrostatic test (see para. 2.5.3). In such cases, attention should be given to gasket selection because of possible excessive deformation of the flange.

8.3 Fitting Shell Tests

The hydrostatic shell test for flanged fittings shall be not less than 1.5 times the 100°F rating rounded off to the next higher 25 psi increment. The test pressure shall be 400 psi for Class 150 and 975 psi for Class 300.

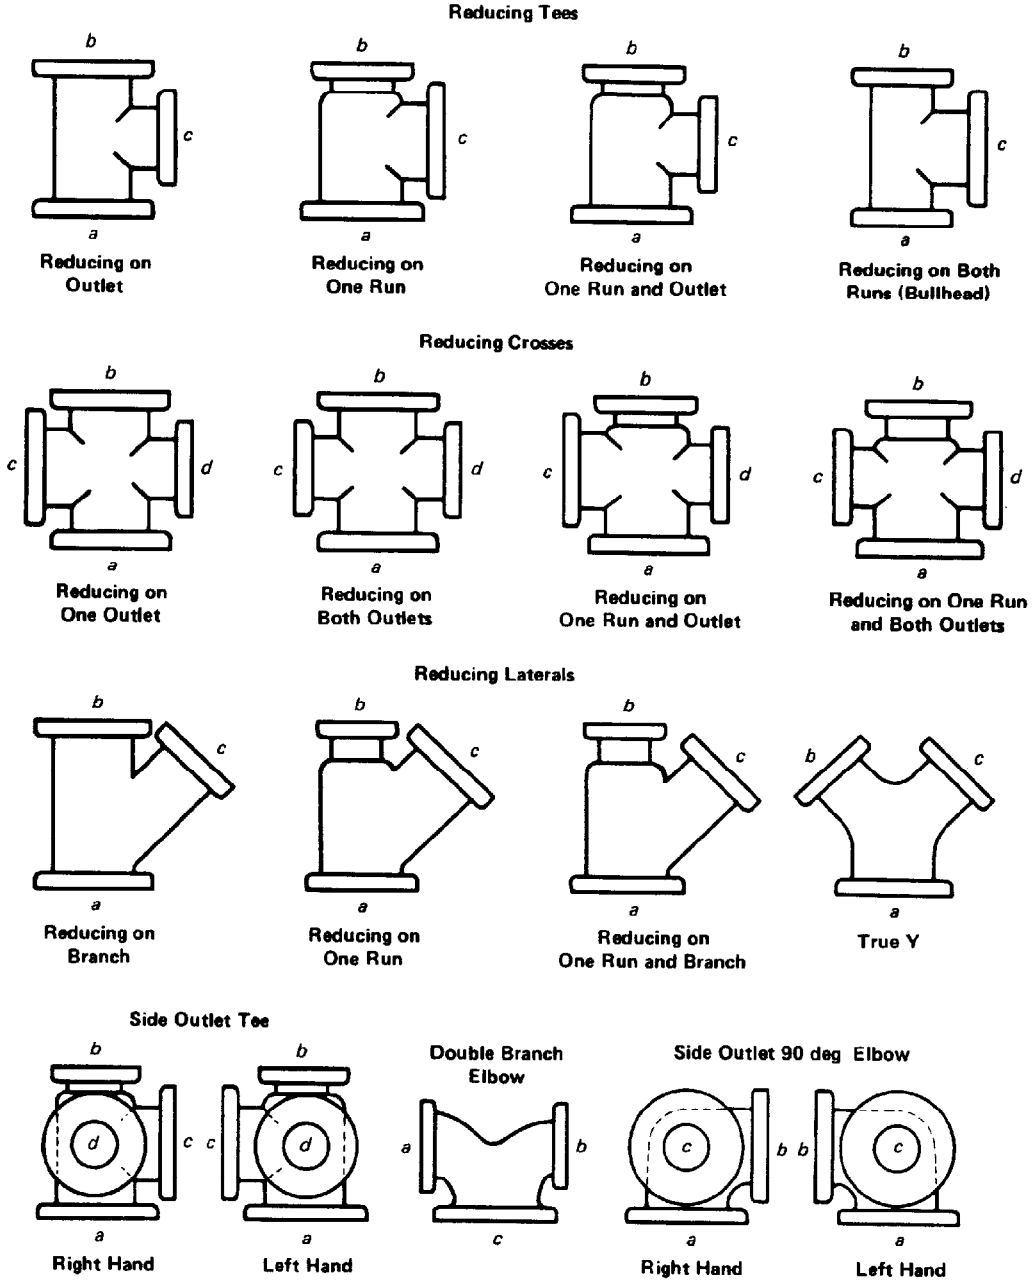
Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:27 2005

(a) The test shall be made with water, or with other suitable fluid provided its viscosity is no greater than that of water, at a test temperature not above 125°F.

(b) The test duration shall be a minimum of 15 sec for fittings NPS 2 and smaller, 60 sec for fittings NPS $2\frac{1}{2}$ through 8, and 3 min for fitting NPS 10 and larger.

(c) No visible leakage is permitted through the pressure boundary wall.

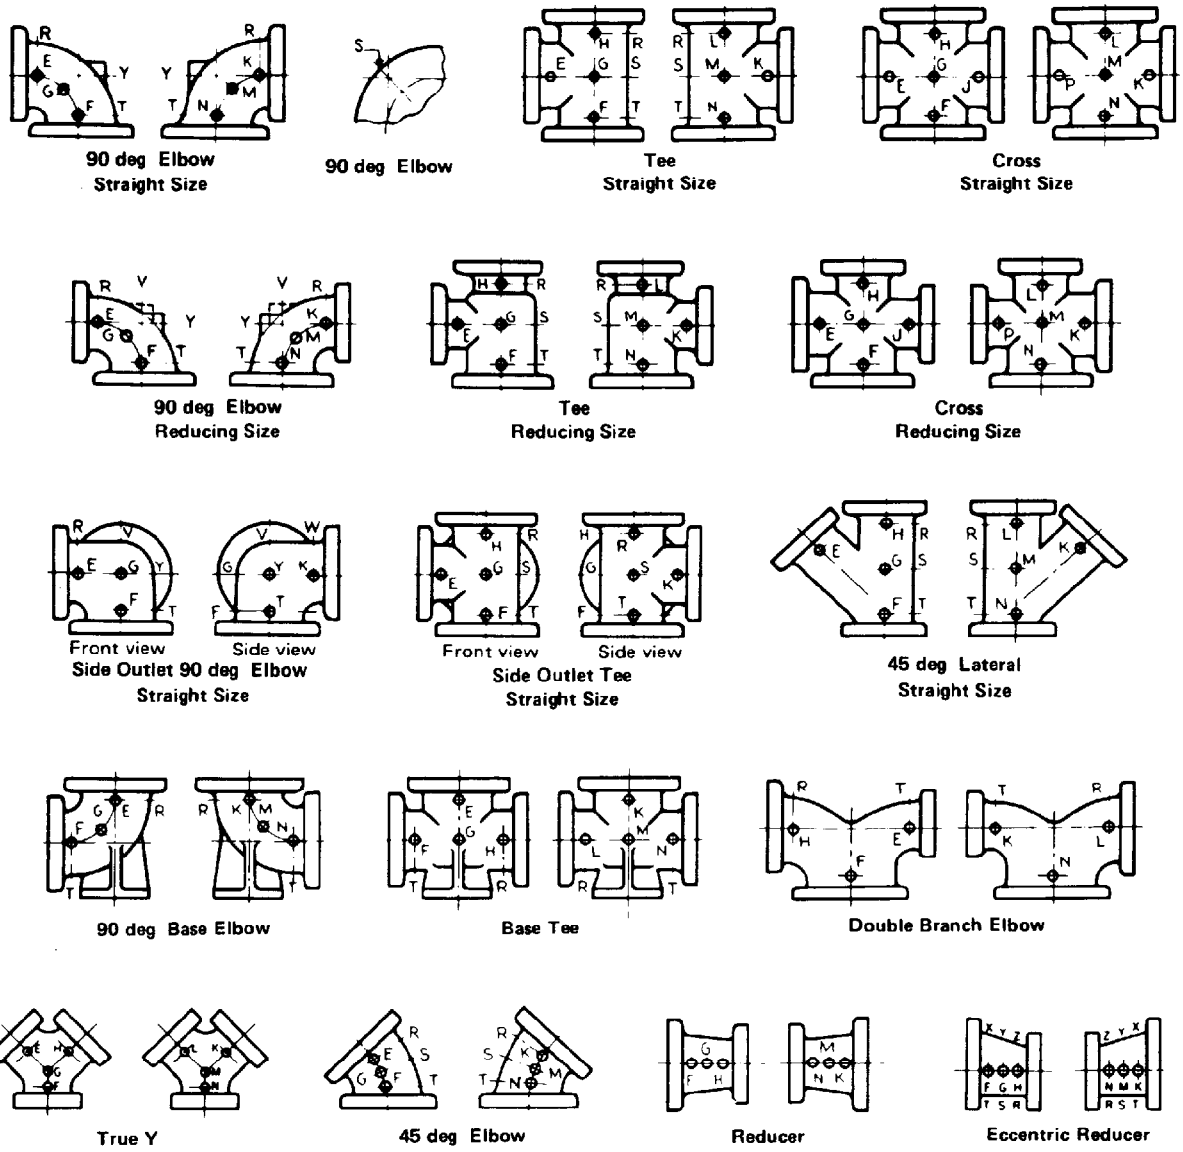
Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:27 2005



GENERAL NOTE:
In designating the outlets of reducing fittings, the openings should be read in the order indicated by the sequence of the letters *a*, *b*, *c*, and *d*. In designating the outlets of side outlet reducing fittings, the side outlet is named last, and in the case of the side outlet cross (which is not shown), the side outlet is designated by the letter *e*.

FIG. 1 METHOD OF DESIGNATING OUTLETS OF REDUCING FITTINGS

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:27 2005



GENERAL NOTE:
The above sketches show two views of the same fitting and represent fittings with symmetrical shapes, with the exception of the side outlet elbow and the side outlet tee (straight sizes).

Blind Flange

TABLE 2 REDUCING THREADED FLANGES FOR CLASSES 150 AND 300

1	2	3	4	5	6
Nominal Pipe Size [Note (4)]	Smallest Size [Note (2)] of Reducing Outlet Requiring Hub Flanges	Nominal Pipe Size [Note (4)]	Smallest Size [Note (2)] of Reducing Outlet Requiring Hub Flanges	Nominal Pipe Size [Note (4)]	Smallest Size [Note (2)] of Reducing Outlet Requiring Hub Flanges
1	½	3½	1½	12	3½
1¼	½	4	1½	14	3½
1½	½	5	1½	16	4
2	1	6	2½	18	4
2½	1¼	8	3	20	4
3	1¼	10	3½	24	4

NOTES:

(1) Class 150 flanges do not have a counterbore. Class 300 flanges will have a depth of counterbore q of 0.25 in. for NPS 2 and smaller tappings and 0.38 in. for NPS 2½ and larger. The diameter of counterbore S is the same as that given in the tables of threaded flanges for the corresponding tapping.

(2) The hub dimensions shall be at least as large as those of the standard flanges of the size to which the reduction is being made, except flanges reducing to a size smaller than those of columns 2, 4, and 6 may be made from blind flanges. See example 2 below.

(3) Minimum length of effective threads shall be at least equal to dimension T of the corresponding pressure class threaded flange as shown in tables, but does not necessarily extend to the face of the flange. For thread of threaded flanges, see para. 6.6.

(4) For method of designating reducing threaded flanges, see para. 3.3 and examples 1 and 2 below.

Example 1: The size designation is NPS 6 × 2½ — Class 300 reducing threaded flange. This flange has the following dimensions:

NPS 2½ — taper pipe thread tapping (ASME B1.20.1)
12.5 in. — diameter of regular NPS 6 Class 300 threaded flange
1.44 in. — thickness of regular NPS 6 Class 300 threaded flange
7.0 in. — diameter of hub for regular NPS 5 Class 300 threaded flange
0.62 in. — height of hub for regular NPS 5 Class 300 threaded flange

Other dimensions the same as for regular NPS 6 Class 300 threaded flange, Table 8.

Example 2: The size designation is NPS 6 × 2 — Class 300 reducing threaded flange. Use regular NPS 6 Class 300 blind flange tapped with NPS 2 taper pipe thread (ASME B1.20.1).

24	24.00	32.00	1.88	26.12	3.25	1.25	27.25	24.25	0.50	4.38

GENERAL NOTES:
(a) Dimensions are in inches.
(b) For tolerances, see Section 7.
(c) For facings, see para. 6.2.
(d) For flange bolt holes, see para. 6.3 and Table 3.
(e) For spot facing, see para. 6.4.
(f) For reducing threaded flanges, see Table 2.
(g) Blind flanges may be made with or without hub at the option of the manufacturer.

NOTES:
(1) This dimension is for large end of the hub, which may be straight or tapered. Taper shall not exceed 7 deg on threaded and lapped flanges.
(2) For thread of threaded flanges, see para. 6.6.

24	23.25	22.00	34.00	11.00	40.50	9.00	24.00	32.00	1.88	0.57

GENERAL NOTES:
(a) Dimensions are in inches; reference Table 5 Illustration on previous page.
(b) For tolerances, see Section 7.
(c) For facings, see para. 6.2.
(d) For flange bolt holes, see para. 6.3 and Table 3.
(e) For spot facing, see para. 6.4.
(f) For center-to-contact surface and center-to-end dimensions of reducing fittings, see para. 6.1.
(g) For contact surface-to-contact surface and end-to-end dimensions of reducers and eccentric reducers, see para. 6.1.
(h) For intersecting center lines, center-to-contact surface, and center-to-end dimensions of side outlet fittings, see para. 6.1.
(i) For center-to-contact surface and center-to-end dimensions of special degree elbows, see para. 6.1.
(j) For drains, see para. 6.9.

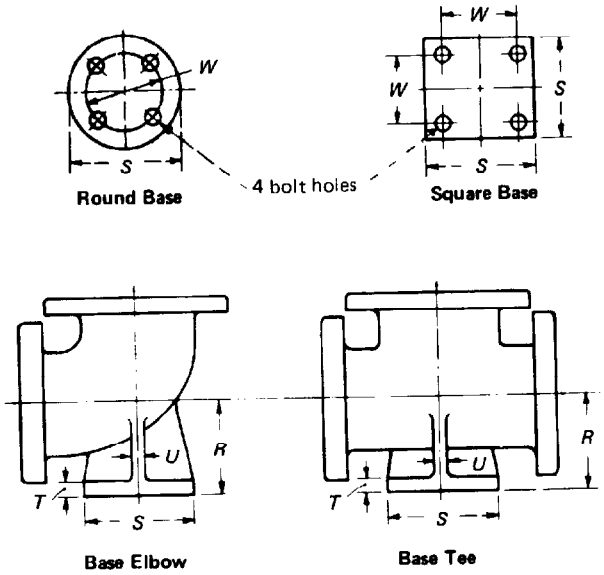

TABLE 6 DIMENSIONS OF CLASS 150 BASE ELBOWS AND BASE TEES

Nominal Pipe Size	Center-to-Base [Note (2)], *R*	Diameter of Round Base or Width of Square Base [Note (3)], *S*	Thickness of Base, *T*	Thickness of Ribs, *U*	Nominal Size of Supporting Pipe for Base	Base Drilling [Note (1)]	
						Bolt Circle or Bolt Spacing, *W*	Diameter of Drilled Holes
2	4.12	4.62	0.50	0.50	1¼	3.50	0.62
2½	4.50	4.62	0.50	0.50	1¼	3.50	0.62
3	4.88	5.00	0.56	0.50	1½	3.88	0.62
3½	5.25	5.00	0.56	0.50	1½	3.88	0.62
4	5.50	6.00	0.62	0.50	2	4.75	0.75
5	6.25	7.00	0.69	0.62	2½	5.50	0.75
6	7.00	7.00	0.69	0.62	2½	5.50	0.75
8	8.38	9.00	0.94	0.88	4	7.50	0.75
10	9.75	9.00	0.94	0.88	4	7.50	0.75
12	11.25	11.00	1.00	1.00	6	9.50	0.88
14	12.50	11.00	1.00	1.00	6	9.50	0.88
16	13.75	11.00	1.00	1.00	6	9.50	0.88
18	15.00	13.50	1.12	1.12	8	11.75	0.88
20	16.00	13.50	1.12	1.12	8	11.75	0.88
24	18.50	13.50	1.12	1.12	8	11.75	0.88

GENERAL NOTES:
(a) Dimensions are in inches.
(b) Bases are not finished unless so ordered.

NOTES:
(1) Bolt hole template shown for round base is the same as for the flange of the supporting pipe size, except using only four holes in all cases so placed as to straddle center lines. The bases of these fittings are intended for support in compression and are not to be used for anchors or supports in tension or shear.
(2) For reducing fittings, the size and center-to-face dimensions of base are determined by the size of the largest opening of fitting. In the case of reducing base elbows, orders shall specify whether the base shall be opposite the larger or smaller opening.
(3) The base dimensions apply to all straight and reducing sizes.

GENERAL NOTES:
(a) Dimensions are in inches; reference Table 8 Illustration on previous page.
(b) For tolerances, see Section 7.
(c) For facing, see para. 6.2.
(d) For flange bolt holes, see para. 6.3 and Table 7.
(e) For spot facing, see para. 6.4.
(f) For reducing threaded flanges, see Table 2.
(g) Blind flanges may be made with or without hub at the option of the manufacturer.

NOTES:
(1) This dimension is for large end of hub, which may be straight or tapered. Taper shall not exceed 7 deg on threaded and lapped flanges.
(2) For thread of threaded flanges, see para. 6.6.

GENERAL NOTES:
(a) Dimensions are in inches.
(b) Bases are not finished unless so ordered.

NOTES:
(1) Bolt hole template shown for round base is the same as for the flange of the supporting pipe size, except using only four holes in all cases so placed as to straddle center lines. The bases of these fittings are intended for support in compression and are not to be used for anchors or supports in tension or shear.
(2) For reducing fittings, the size and center-to-face dimensions of bases are determined by the size of the largest opening of fitting. In the case of reducing base elbows, orders shall specify whether the base shall be opposite the larger or smaller opening.
(3) The base dimensions shall apply to all straight and reducing sizes.

ANNEX A
METHODS FOR ESTABLISHING PRESSURE–TEMPERATURE RATINGS

(This Annex is an integral part of ASME B16.42-1998 and is placed after the main text for convenience.)

A1 GENERAL

A1.1 Introduction

Pressure-temperature ratings in this Standard have been determined by the procedures in this Annex. The primary consideration in establishing ratings is adequate wall thickness to sustain stresses due to pressure and other loadings. See para. A1.2. Other considerations affecting or limiting the ratings include:

(a) stresses in flanges resulting from bolt-up necessary to maintain gasket seal;

(b) distortion of flanges and flanged fittings due to loadings transmitted through the pipeline;

(c) limitations applying primarily to valves but imposed also on flanges in order to maintain compatible ratings.

A1.2 Wall Thickness

Wall thickness requirements for flanged fittings are set forth in para. 7.1, and minimum thicknesses t_m are listed in the tables designated in para. 7.1. These values are all greater than those determined by Eq. (1).

$$t = 1.5\,P_c d/(2S - 1.2P_c) \quad (1)$$

where

t = calculated thickness, in.
P_c = pressure rating class designation expressed in psi (e.g., P_c = 150 psi for Class 150)
d = inside diameter of the fitting, in.
S = stress factor of 7000 psi

Equation (1) gives thickness 50% greater than for a simple cylinder designed for a stress of 7000 psi when subjected to an internal pressure equal to the pressure rating class designation in psi. Actual values in the dimension tables listed in para. 7.1 are approximately 0.1 in. to 0.2 in. heavier than those given by the equation.

A2 RATINGS IN CUSTOMARY UNITS

A2.1 Ambient Rating Equation

Ratings for −20°F to 100°F temperatures for all pressure classes are established by Eq. (2).

$$P_T = P_r S_1/8750 \quad (2)$$

where

P_T = rated working pressure, psig, for the material at temperature T
P_r = pressure rating class index expressed in psi (P_r = 300 psi for Class 300 and P_r = 115 psi for Class 150)
S_1 = selected stress, psi

The selected stress S_1 shall be the lowest of the following values:

(a) 60% of specified minimum yield strength at 100°F.

(b) 1.25 times the allowable stress at 100°F. The allowable stress shall be determined by the rules of the ASME Boiler and Pressure Vessel Code, Section I, Appendix A-150.

$$S_1 = 31{,}300 - (T^2/49.85) \quad (3)$$

Using 100 as the value for T, Eq. (3) establishes an upper limit for bolt loads approximating 125% of allowable stress for ASTM A 193 Grade B7 bolting.

A2.2 Ratings for Class 150

Pressure-temperature ratings for Class 150 flanges and flanged fittings are determined as follows.

(a) The value for p_T at temperature T (°F) for temperatures from 400°F to 650°F shall be that given by Eq. (4).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:32 2005

STD.ASME B16.42-ENGL 1998 ■ 0759670 0609023 193 ■

$$p_T = 320 - 0.3T \quad (4)$$

The limits of T are 400°F min. and 650°F max.

(b) The values for p_T between 100°F and 400°F shall be determined by linear interpolation of the values calculated for p_T at 100°F using Eqs. (2) and (4).

A2.3 Ratings for Class 300

Pressure-temperature ratings for Class 300 flanges and flanged fittings are determined as follows.

(a) The value for p_T at temperature T (°F) for temperatures from 400°F to 650°F shall be that given by Eq. (5).

$$p_T = 645 - 0.3T \quad (5)$$

The limits of T are 400°F min. and 650°F max.

(b) The values for p_T between 100°F and 400°F shall be determined by linear interpolation of the values calculated for p_T at 100°F and 400°F using Eqs. (2) and (5).

ANNEX C
QUALITY SYSTEM PROGRAM

(This is a nonmandatory part of ASME B16.42-1998 and is provided for informational purposes only.)

The products manufactured in accordance with this Standard shall be produced under a quality system program following the principles of an appropriate standard from the ISO 9000 series.[1] A determination of the need for registration and/or certification of the product manufacturer's quality system program by an independent organization shall be the responsibility of the manufacturer. The detailed documentation demonstrating program compliance shall be available to the purchaser at the manufacturer's facility. A written summary description of the program utilized by the product manufacturer shall be available to the purchaser upon request. The product manufacturer is defined as the entity whose name or trademark appears on the product in accordance with the marking or identification requirements of this Standard.

[1] The series is also available from the American National Standards Institute (ANSI) and the American Society for Quality Control (ASQC) as American National Standards that are identified by a prefix "Q" replacing the prefix "ISO." Each standard of the series is listed under Annex C.

Date of Issuance: October 26, 1998

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment that provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assumes any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

ASME B16.47a–1998

Following approval by the ASME B16 Committee and ASME, and after public review, ASME B16.47a-1998 was approved by the American National Standards Institute on February 20, 1998.

Addenda to the 1996 Edition of ASME B16.47 are issued in the form of replacement pages. Revisions, additions, and deletions are incorporated directly into the affected pages. It is advisable, however, that this page, the Addenda title and copyright pages, and all replaced pages be retained for reference.

SUMMARY OF CHANGES

This is the first Addenda to be published to ASME B16.47-1996.

Replace or insert the pages listed. Changes given below are identified on the pages by a margin note, **(a)**, placed next to the affected area. The pages not listed are the reverse sides of the listed pages and contain no changes.

FOREWORD (a)

(This Foreword is not part of ASME B16.47-1996.)

In November, 1980, a task force was appointed within Subcommittee C of the American National Standards (ANSI) B16 Committee to develop a standard for pipe flanges in size NPS 26 through NPS 48. Every attempt was made to standardize those dimensions that existed within the industry for the materials covered by ANSI B16.5.

Prompted by suggestions received from committee members, the task force was authorized to increase the size range to NPS 60. The first draft was developed in December 1982 to include Class 75 through Class 1500 for the size range NPS 26 through NPS 60. Flange dimensions were based on the Manufacturers Standardization Society Standard Practice (MSS SP) 44 flanges except for Class 75 flanges which are ANSI/API 605 flanges.

At the request of the American Petroleum Institute (API), flange dimensions in accordance with the API Standard 605 were included in the subsequent drafts. Class 1500 flanges were deleted due to lack of interest in using large size flanges in that pressure–temperature rating.

The API-605 flanges for Classes 150 and 300 and for sizes NPS 36 and smaller for classes higher than Class 300 are not compatible with the MSS SP-44 flanges. Thus, the MSS SP-44 flanges are designated as Series A flanges and the API-605 flanges are designated as Series B flanges in this Standard. Materials covered in this Standard are as in ANSI B16.5 except nickel base alloys are excluded. Pressure–temperature ratings are in accordance with ANSI B16.5.

In 1982, American National Standards Committee B16 was reorganized as the American Society of Mechanical Engineers (ASME) B16 Committee operating under procedures accredited by ANSI. Following approval by the Standards Committee and ASME, approval as an American National Standard was given by ANSI on June 12, 1990.

This 1996 Edition allows flanges marked with more than one material grade or specification, revises flange facing finish requirements, has revised pressure–temperature ratings for several material groups, adds permissible flange facing imperfections, adds blind flanges for Series B flanges, and includes several other revisions. Following approval by the Standards Committee and ASME, approval as an American National Standard was given by ANSI on October 3, 1996 with the new designation ASME B16.47-1996.

All requests for interpretations or suggestions for revisions should be sent to the Administrative Secretary B16, The American Society of Mechanical Engineers, Three Park Avenue, New York, NY 10016-5990.

LARGE DIAMETER STEEL FLANGES

1 SCOPE

1.1 General

This Standard covers pressure–temperature ratings, materials, dimensions, tolerances, marking, and testing for pipe flanges in sizes NPS 26 through NPS 60 and in ratings Classes 75, 150, 300, 400, 600, and 900. Flanges may be cast, forged, or plate (for blind flanges only) materials, as listed in Table 1A.

Requirements and recommendations regarding bolting and gaskets are also included.

1.2 Flange Series

This Standard provides two series of flange dimensions. Series A specifies flange dimensions for general use flanges. Series B specifies flange dimensions for compact flanges which, in general, have smaller bolt circle diameters than Series A flanges. These two series of flanges are not interchangeable. The user should recognize that some flanged valves, equipment bolted between flanges, and flanged equipment may only be compatible with bolt circle diameter of one series of flanges.

1.3 References

1.3.1 Referenced Standards. Standards and specifications adopted by reference in this Standard are shown in Annex E, which is part of this Standard. It is not considered practical to identify the specific edition of each standard and specification in the individual references. Instead, the specific edition reference is identified in Annex E. A flange manufactured in accordance with earlier editions of the referenced standards, and in all other respects conforming to this Standard, will be considered to be in conformance with this Standard.

1.3.2 Codes and Regulations. A flange used under the jurisdiction of the ASME Boiler and Pressure Vessel Code (ASME BPV Code), the ASME Code for Pressure Piping, or a governmental regulation is subject to any limitation of that code or regulation. This includes any maximum temperature limitation, rule governing the use of a material at low temperature, or provisions for operation at a pressure exceeding the pressure–temperature ratings in this Standard.

1.4 Applicable Ratings

The pressure–temperature ratings in this Standard are applicable upon its publication to all flanges within its scope which otherwise meet its requirements. For unused flanges maintained in inventory, the manufacturer of the flange may certify conformance to this Edition, provided he can demonstrate that all requirements of this Edition have been met. Where such components were installed in accordance with the pressure–temperature ratings of an earlier edition of this Standard, those ratings are applicable, except as may be governed by the applicable code or regulation (see para. 1.3.2).

1.5 User Accountability

This Standard cites duties and responsibilities that are to be assumed by the user in the areas of application, installation, hydrostatic testing, operation, and material selection.

1.6 Quality Systems

Nonmandatory requirements relating to the product manufacturer's Quality System Program are described in Annex D.

2 PRESSURE–TEMPERATURE RATINGS

2.1 Rating Basis

Ratings are maximum allowable working gage pressures, at the temperatures shown in Table 2 for the applicable material and rating. For intermediate temperatures, linear interpolation is permitted. See Annex A for methods of establishing pressure–temperature ratings.

2.2 Ratings of Flanged Joints

A flanged joint is composed of three separate and independent, although interrelated, components: the flanges, the gasket, and the bolting, which are assembled by yet another influence, the assembler. Proper controls must be exercised in the selection and application for all these elements in order to attain a joint which has

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:58 2005

acceptable leak tightness. Special techniques such as controlled bolt tightening may be necessary to achieve a tight joint in service.

Ratings in this Standard apply to flanged joints which conform to the limitations on bolting in para. 5.3 and on gaskets in para. 5.4, and which are made up in accordance with good practice for alignment and assembly. See also para. 2.4. Use of the ratings for flanged joints not conforming to these limitations is the sole responsibility of the user. Requirements for alignment and assembly of joints are not given in this Standard.

If the two flanges in a flanged joint do not have the same pressure–temperature ratings, the rating of the joint at any temperature is the lower of the two flange ratings at that temperature.

2.3 Rating Temperature

The temperature shown for a corresponding pressure rating is the temperature of the pressure containing shell of the flange. In general, this temperature is the same as that of the contained fluid. Use of a pressure rating corresponding to a temperature other than that of the contained fluid is the responsibility of the user, subject to the requirements of the applicable code or regulation. For any temperature below −20°F the rating shall be no greater than the rating shown for −20°F.

(a) 2.4 Temperature Considerations

Application of the ratings in this Standard to flanged joints at both high and low temperatures shall take into consideration the risk of leakage due to forces and moments developed in the connected piping or equipment. The following provisions are intended to minimize these risks.

2.4.1 High Temperature Service. At temperatures in the creep range, gradual relaxation of flanges, bolts, and gaskets may progressively reduce bolt loads. It may be necessary to arrange for periodic tightening of bolts to prevent leakage. Joints subject to substantial thermal gradients may require the same attention.

When used above 400°F, Classes 75 and 150 flanged joints may develop leakage unless care is taken to avoid imposing severe external loads and/or severe thermal gradients. For other classes, similar consideration should be given above 750°F.

2.4.2 Low Temperature Service. Some of the materials listed in the rating tables undergo sufficient decrease in toughness at low temperatures that they cannot safely sustain shock loadings, sudden changes of stress or temperature, or high stress concentrations.

2.5 System Hydrostatic Test

Flanged joints may be subjected to system hydrostatic tests at a pressure not to exceed 1.5 times the 100°F rating rounded off to the next higher 25 psi.

Testing at any higher pressure is the responsibility of the user, subject to the requirements of the applicable code or regulation.

2.6 Welding Neck Flanges

Ratings for carbon steel cylindrically bored welding neck flanges covered by this Standard are based upon their hubs at the welding end having a thickness at least equal to that calculated for pipe having 40.0 ksi specified minimum yield strength. The ratings also apply to such flanges used with components of unequal strength and unequal wall thickness when the attachment welds is made in accordance with the applicable code or regulation. See Figs. 5, 6, and 7.

2.7 Multiple Material Grades

Materials for flanges may meet the requirements for more than one specification or grade of a specification listed in Table 1A. In that event, the pressure–temperature ratings for any of these specifications or grades may be used provided that the marking is in accordance with para. 4.1.2(d).

3 SIZE

3.1 Nominal Size

The size of a flange covered by this Standard is its nominal pipe size (NPS). The diameter of a bolt is its nominal size. Use of nominal indicates that the stated size or dimension is only for designation, not measurement. The actual dimension may or may not be the nominal size and is subject to established tolerances.

4 MARKING

4.1 General

Except as modified herein, flanges shall be marked as required in MSS SP-25.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:52:58 2005

7.6.2 Center-to-center of adjacent bolt holes, 0.03 in.

7.6.3 Eccentricity between bolt circle diameter and machined facing diameters, 0.06 in.

8 TEST

8.1 Flange Testing

Flanges are not required to be hydrostatically tested.

GENERAL NOTE:
Bolting material shall not be used beyond temperature limits specified in the governing code.

NOTES:
(1) Repair welding of bolting material is prohibited.
(2) These bolting materials may be used with all listed materials and gaskets.
(3) These bolting materials may be used with all listed materials and gaskets, provided it has been verified that a sealed joint can be maintained under rated working pressure and temperature.
(4) These bolting materials may be used with all listed materials but are limited to Class 150 and Class 300 joints. See para. 5.4.1 for recommended gasket practices.
(5) This austenitic stainless material has been carbide solution treated but not strain hardened. Use A 194 nuts of corresponding material.
(6) This ferritic material is intended for low temperature service. Use A 194 Gr. 4 or Gr. 7 nuts.
(7) This austenitic stainless material has been carbide solution treated and strain hardened. Use A 194 nuts of corresponding material.
(8) This carbon steel fastener shall not be used above 400°F or below −20°F. See also Note (4). Bolts with drilled or undersized heads shall not be used.
(9) Acceptable nuts for use with quenched and tempered bolts are A 194 Gr. 2 and Gr. 2H. Mechanical property requirements for studs shall be the same as those for bolts.
(10) This special alloy is intended for high temperature service with austenitic stainless steel.
(11) ASME Boiler and Pressure Vessel Code, Section II materials, which also meet the requirements of the listed ASTM specifications, may also be used.

INTERPRETATIONS TO ASME B16.47 (a)

(These interpretations are not part of ASME B16.47-1996 and are included for information only. These interpretations apply to the 1988 and earlier editions and the requirements cited may be different in this Edition. Therefore, some replies may not be valid in regard to this Edition.)

INTRODUCTION

As a service to persons who use the B16 standards, the B16 Committee renders interpretations of the requirements upon request. The procedure for requesting an interpretation is described in the following paragraphs.

The interpretations include all replies which have been approved by the B16 Main Committee in response to inquiries concerning interpretation of this Standard.

An interpretation applies either to the Edition and Addenda in effect on the date of issuance of the interpretation or the Edition and Addenda stated in the interpretation. Subsequent revisions to this Standard may supersede the interpretation.

PROCEDURE FOR REQUESTING INTERPRETATIONS

On request, the B16 Committee will render an interpretation of any requirement of this Standard. Interpretations can only be rendered in response to a written request, which should be addressed to:

Secretary, B16 Main Committee
The American Society of Mechanical Engineers
Three Park Avenue
New York, NY 10016-5990

The request for interpretation should be clear and unambiguous. It is further recommended that the inquirer submit his request using the following format:

(a) Subject. Cite the applicable paragraph number(s) and/or give a concise description of the subject.

(b) Question. Phrase the question as a request for an interpretation of a specific requirement suitable for general understanding and use, not as a request for an approval of a proprietary design or situation. The inquirer may also include any plans or drawings which are necessary to explain the question; however, they should not contain proprietary names or information.

Requests which are not in this format may be rewritten in this format prior to being answered, which may inadvertently change the original intent of the request.

ASME procedures provide for reconsideration of an interpretation when or if additional information is available which the inquire believes might affect the interpretation. Further, persons aggrieved by an interpretation may appeal to the cognizant ASME committee or subcommittee. ASME does not "approve," "certify," "rate," or "endorse" any item, construction, proprietary device, or activity.

INTERPRETATIONS NO. 2

Replies to Technical Inquiries Issued from January 1, 1996 Through December 31, 1997

Interpretation: 2-1

Subject: Series A Flanges

Date Issued: April 30, 1997

File: B16-96-013

Question: According to ASME B16.47-1990, may Series A flanges be manufactured and used for all materials listed in Table 1A?

Reply: Yes, within the restriction of General Note (b) of Table 1A.

Date of Issuance: January 31, 1997

The 1996 edition of this Standard is being issued with an automatic addenda subscription service. The use of an addenda allows revisions made in response to public review comments or committee actions to be published as necessary; revisions published in addenda will become effective 6 months after the Date of Issuance of the addenda. The next edition of this Standard is scheduled for publication in 2001.

ASME issues written replies to inquiries concerning interpretations of technical aspects of this Standard. The interpretations will be included with the above addenda service. Interpretations are not part of the addenda to the Standard.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Consensus Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,

FOREWORD

(This Foreword is not part of ASME B16.47-1996.)

In November, 1980, a task force was appointed within Subcommittee C of the American National Standards (ANSI) B16 Committee to develop a standard for pipe flanges in size NPS 26 through NPS 48. Every attempt was made to standardize those dimensions that existed within the industry for the materials covered by ANSI B16.5.

Prompted by suggestions received from committee members, the task force was authorized to increase the size range to NPS 60. The first draft was developed in December 1982 to include Class 75 through Class 1500 for the size range NPS 26 through NPS 60. Flange dimensions were based on the Manufacturers Standardization Society Standard Practice (MSS SP) 44 flanges except for Class 75 flanges which are ANSI/API 605 flanges.

At the request of the American Petroleum Institute (API), flange dimensions in accordance with the API Standard 605 were included in the subsequent drafts. Class 1500 flanges were deleted due to lack of interest in using large size flanges in that pressure–temperature rating.

The API-605 flanges for Classes 150 and 300 and for sizes NPS 36 and smaller for classes higher than Class 300 are not compatible with the MSS SP-44 flanges. Thus, the MSS SP-44 flanges are designated as Series A flanges and the API-605 flanges are designated as Series B flanges in this Standard. Materials covered in this Standard are as in ANSI B16.5 except nickel base alloys are excluded. Pressure–temperature ratings are in accordance with ANSI B16.5.

In 1982, American National Standards Committee B16 was reorganized as the American Society of Mechanical Engineers (ASME) B16 Committee operating under procedures accredited by ANSI. Following approval by the Standards Committee and ASME, approval as an American National Standard was given by ANSI on June 12, 1990.

This 1996 Edition allows flanges marked with more than one material grade or specification, revises flange facing finish requirements, has revised pressure–temperature ratings for several material groups, adds permissible flange facing imperfections, adds blind flanges for Series B flanges, and includes several other revisions. Following approval by the Standards Committee and ASME, approval as an American National Standard was given by ANSI on October 3, 1996 with the new designation ASME B16.47-1996.

All requests for interpretations or suggestions for revisions should be sent to the Administrative Secretary B16, The American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017.

LARGE DIAMETER STEEL FLANGES

1 SCOPE

1.1 General

This Standard covers pressure–temperature ratings, materials, dimensions, tolerances, marking, and testing for pipe flanges in sizes NPS 26 through NPS 60 and in ratings Classes 75, 150, 300, 400, 600, and 900. Flanges may be cast, forged, or plate (for blind flanges only) materials, as listed in Table 1A.

Requirements and recommendations regarding bolting and gaskets are also included.

1.2 Flange Series

This Standard provides two series of flange dimensions. Series A specifies flange dimensions for general use flanges. Series B specifies flange dimensions for compact flanges which, in general, have smaller bolt circle diameters than Series A flanges. These two series of flanges are not interchangeable. The user should recognize that some flanged valves, equipment bolted between flanges, and flanged equipment may only be compatible with bolt circle diameter of one series of flanges.

1.3 References

1.3.1 Referenced Standards. Standards and specifications adopted by reference in this Standard are shown in Annex E, which is part of this Standard. It is not considered practical to identify the specific edition of each standard and specification in the individual references. Instead, the specific edition reference is identified in Annex E. A flange manufactured in accordance with earlier editions of the referenced standards, and in all other respects conforming to this Standard, will be considered to be in conformance with this Standard.

1.3.2 Codes and Regulations. A flange used under the jurisdiction of the ASME Boiler and Pressure Vessel Code (ASME BPV Code), the ASME Code for Pressure Piping, or a governmental regulation is subject to any limitation of that code or regulation. This includes any maximum temperature limitation, rule governing the use of a material at low temperature, or provisions for operation at a pressure exceeding the pressure–temperature ratings in this Standard.

1.4 Applicable Ratings

The pressure–temperature ratings in this Standard are applicable upon its publication to all flanges within its scope which otherwise meet its requirements. For unused flanges maintained in inventory, the manufacturer of the flange may certify conformance to this Edition, provided he can demonstrate that all requirements of this Edition have been met. Where such components were installed in accordance with the pressure–temperature ratings of an earlier edition of this Standard, those ratings are applicable, except as may be governed by the applicable code or regulation (see para. 1.3.2).

1.5 User Accountability

This Standard cites duties and responsibilities that are to be assumed by the user in the areas of application, installation, hydrostatic testing, operation, and material selection.

1.6 Quality Systems

Nonmandatory requirements relating to the product manufacturer's Quality System Program are described in Annex D.

2 PRESSURE–TEMPERATURE RATINGS

2.1 Rating Basis

Ratings are maximum allowable working gage pressures, at the temperatures shown in Table 2 for the applicable material and rating. For intermediate temperatures, linear interpolation is permitted. See Annex A, which is part of this Standard, for methods of establishing pressure–temperature ratings.

2.2 Ratings of Flanged Joints

A flanged joint is composed of three separate and independent, although interrelated, components: the flanges, the gasket, and the bolting, which are assembled by yet another influence, the assembler. Proper controls must be exercised in the selection and application for

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:10 2005

all these elements in order to attain a joint which has acceptable leak tightness. Special techniques such as controlled bolt tightening may be necessary to achieve a tight joint in service.

Ratings in this Standard apply to flanged joints which conform to the limitations on bolting in para. 5.3 and on gaskets in para. 5.4, and which are made up in accordance with good practice for alignment and assembly. See also para. 2.4. Use of the ratings for flanged joints not conforming to these limitations is the sole responsibility of the user. Requirements for alignment and assembly of joints are not given in this Standard.

If the two flanges in a flanged joint do not have the same pressure–temperature ratings, the rating of the joint at any temperature is the lower of the two flange ratings at that temperature.

2.3 Rating Temperature

The temperature shown for a corresponding pressure rating is the temperature of the pressure containing shell of the flange. In general, this temperature is the same as that of the contained fluid. Use of a pressure rating corresponding to a temperature other than that of the contained fluid is the responsibility of the user, subject to the requirements of the applicable code or regulation. For any temperature below –20°F the rating shall be no greater than the rating shown for –20°F.

2.4 Temperature Considerations

Application of the ratings in this Standard to flanged joints both high and low temperatures shall take into consideration the risk of leakage due to forces and moments developed in the connected piping or equipment. The following provisions are intended to minimize these risks.

2.4.1 High Temperature Service. At temperatures in the creep range, gradual relaxation of flanges, bolts, and gaskets may progressively reduce bolt loads. It may be necessary to arrange for periodic tightening of bolts to prevent leakage. Joints subject to substantial thermal gradients may require the same attention.

When used above 400°F, Classes 75 and 150 flanged joints may develop leakage unless care is taken to avoid imposing severe external loads and/or severe thermal gradients. For other classes, similar consideration should be given above 750 F.

2.4.2 Low Temperature Service. Some of the materials listed in the rating tables undergo sufficient decrease in toughness at low temperatures that they cannot safely sustain shock loadings, sudden changes of stress or temperature, or high stress concentrations.

2.5 System Hydrostatic Test

Flanged joints may be subjected to system hydrostatic tests at a pressure not to exceed 1.5 times the 100°F rating rounded off to the next higher 25 psi.

Testing at any higher pressure is the responsibility of the user, subject to the requirements of the applicable code or regulation.

2.6 Welding Neck Flanges

Ratings for carbon steel cylindrically bored welding neck flanges covered by this Standard are based upon their hubs at the welding end having a thickness at least equal to that calculated for pipe having 40.0 ksi specified minimum yield strength. The ratings also apply to such flanges used with components of unequal strength and unequal wall thickness when the attachment welds is made in accordance with the applicable code or regulation. See Figs. 5, 6, and 7.

2.7 Multiple Material Grades

Materials for flanges may meet the requirements for more than one specification or grade of a specification listed in Table 1A. In that event, the pressure–temperature ratings for any of these specifications or grades may be used provided that the marking is in accordance with para. 4.1.2(d).

3 SIZE

3.1 Nominal Size

The size of a flange covered by this Standard is its nominal pipe size (NPS). The diameter of a bolt is its nominal size. Use of nominal indicates that the stated size or dimension is only for designation, not measurement. The actual dimension may or may not be the nominal size and is subject to established tolerances.

4 MARKING

4.1 General

Except as modified herein, flanges shall be marked as required in MSS SP-25.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:10 2005

4.1.1 Name. The manufacturer's name or trademark shall be applied.

4.1.2 Materials

(a) Cast flanges shall be marked with the ASTM specification[1], grade identification symbol, and the melt number identification or melt identification.

(b) Plate flanges and forged flanges shall be marked with the ASTM specification number and grade identification symbol.

(c) A manufacturer may supplement these mandatory material indications with his trade designation for the material grade, but confusion of symbols shall be avoided.

(d) Flanges manufactured from material which meets the requirements for more than one specification or grade of a specification listed in Table 1A may be marked with more than one of the applicable specification or grade symbols. The symbols shall be placed to avoid confusion in identification.

4.1.3 Rating Class. The marking shall be the applicable pressure rating class: 75 (Series B only), 150, 300, 400, 600, or 900.

4.1.4 Designation. The designation of Series A B16/A for flange dimensions in accordance with Tables 5 through 9 and Series B B16/B for flange dimensions in accordance with Tables 10 through 15 shall be applied, preferably located adjacent to the class designation, to indicate conformance to this Standard.

4.1.5 Temperature. No temperature markings are required on flanges, but if marked, the temperature shall be shown with its corresponding tabulated pressure rating for the material.

4.1.6 Size. The nominal pipe size shall be given.

4.1.7 Ring-Joint Flange. The edge (periphery) of each ring-joint flange shall be marked with the letter "R" and the corresponding ring-groove number.

5 MATERIALS

5.1 General

Flanges covered by this Standard shall be castings, forgings, and (for blind flanges only) plate, as listed in Table 1A. Recommended bolting materials are listed in Table 1B. (See also para. 5.3.) The ASME Boiler and Pressure Vessel Code, Section II materials, which also meet the requirements of the specifications listed in Table 1, may also be used.

5.1.1 Application. Criteria for the selection of materials are not within the scope of this Standard. The possibility of material deterioration in service should be considered by the user. Carbide phase conversion to graphite and excessive oxidation of ferritic materials or susceptibility to intergranular corrosion of austenitic materials are among those items requiring attention. A detailed discussion of precautionary considerations can be found in Appendix F of ASME B31.3.

5.1.2 Toughness. Some of the materials listed in Table 1A undergo a decrease in toughness when used at low temperatures, to the extent that codes referencing this Standard may require impact tests for applications even at temperatures higher than +20°F. It is the responsibility of the user to assure that such testing is performed.

5.1.3 Responsibility. When service conditions dictate the implementation of special material requirements, e.g., using a Group 2 material above 1000°F, it is the user's responsibility to so specify to the manufacturer in order to ensure compliance with metallurgical requirements listed in the notes in Table 2.

5.2 Mechanical Properties

Mechanical properties shall be obtained from test specimens that represent the final heat-treated condition of the material.

5.3 Bolting

Bolting listed in Table 1B is recommended for use in flange joints covered by this Standard. Bolting of other material may be used if permitted by the applicable code or governmental regulation. All bolting materials are subject to the following limitations.

5.3.1 High Strength Bolting. Bolting materials having allowable stresses not less than those for ASTM A 193 Gr. B7 are listed as high strength in Table 1B. These and other materials of comparable strength may be used in any flanged joint.

5.3.2 Intermediate Strength Bolting. Bolting materials listed as intermediate strength in Table 1B, and other bolting of comparable strength, may be used in any flanged joint, provided the user verifies their

[1] The ASME Boiler and Pressure Vessel Code, Section II specification number may be substituted provided the material is covered by Section II.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:11 2005

ability to seat the selected gasket and to maintain a sealed joint under expected operating conditions.

5.3.3 Low Strength Bolting. Bolting materials having not more than 30 ksi specified minimum yield strength are listed as low strength in Table 1B. These materials and others of comparable strength shall be used only in Classes 75, 150, and 300 joints, and only with gaskets described in para. 5.4.1. Flanged joints using low strength carbon steel bolts shall not be used above 400°F or below −20°F.

5.3.4 Bolting to Gray Cast Iron Flanges. The following recommendations are made in recognition of the low ductility of gray cast iron.

(a) Where Class 150 steel flanges are bolted to Class 125 cast iron flanges, the gaskets should be made of Group Ia materials, the steel flanges should have flat faces, and:

(1) low strength bolting within the limitations of para. 5.3.3 should be used with ring gaskets extending to the bolt holes; or

(2) bolting of low (para. 5.3.3), intermediate (para. 5.3.2), or high (para. 5.3.1) strength may be used with full face gaskets extending to the outside diameters of the flanges.

(b) Where Class 300 steel flanges are bolted to Class 250 cast iron flanges, the gaskets should be made of Group Ia materials and:

(1) low strength bolting within the limitations of para. 5.3.3 should be used with gaskets extending to the bolt holes and with flanges having either raised or flat faces; or

(2) bolting of low (para. 5.3.3), intermediate (para. 5.3.2), or high (para. 5.3.1) strength may be used with full face gaskets extending to the outside diameters of the flanges and with both the Class 300 steel and Class 250 cast iron flanges having flat faces.

(c) Alignment of flange faces is essential along with control of assembly bolt torque so as not to over-stress the cast iron flanges. Care must also be exercised to ensure that piping loads transmitted to cast iron flanges are controlled taking into account its lack of ductility and recognizing that cast iron flanges should not be used where suddenly applied loads such as rapid pressure fluctuations may occur.

5.4 Gaskets

Ring-joint gasket materials shall conform to ASME B16.20. Materials for other gaskets are described in Annex B, which is part of this Standard. The user is responsible for selection of gasket materials which will withstand the expected bolt loading without injurious crushing, and which are suitable for the service conditions. Particular attention should be given to gasket selection if a system hydrostatic test approaches the test pressure specified in para. 2.5.

5.4.1 Gaskets for Low Strength Bolting. If bolting listed as low strength in Table 1B is used, gaskets shown in Annex B, Fig. B1, Group Ia, shall be used.

5.4.2 Gaskets for Class 150 Flanged Joints. It is recommended that only Fig. B1, Group Ia or Ib gaskets be used for Class 150 flanged joints.

5.4.3 Gaskets for Class 75 Flanged Joints. It is recommended that only Group Ia gaskets with a gasket factor $m = 2$ or less, and minimum design seating stress $y = 1600$ psi or less, be used. The m and y factors are those given in Table 2-5.1, Appendix 2 of the ASME Boiler and Pressure Vessel Code, Section VIII, Division 1.

6 DIMENSIONS

6.1 Facings

6.1.1 General. Classes 75, 150, and 300 flanges are regularly furnished with a 0.06 in. raised face, which is included in the minimum flange thickness *C*. Classes 400, 600, and 900 flanges are regularly furnished with 0.25 in. raised face, which is additional to the minimum flange thickness *C*. It is recommended that the Class 75 flanges be used only with a 0.06 in. raised face or flat face.

Dimensions for ring-joint facing are given in Table 3 for Series A flanges. Any other facing than the above, when required for any class, shall be furnished as follows.

6.1.1.1 In the case of the 0.25 in. raised face for Classes 150 and 300, the minimum flange thickness *C* shall first be provided and then the raised face shall be added thereto.

6.1.1.2 With ring-joint, the minimum flange thickness shall first be provided and then sufficient metal added thereto so that the bottom of the ring-joint groove is in the same plane as the flange edge of a full thickness flange.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:11 2005

6.1.2 Blind Flanges. Blind flanges need not be faced in the center if, when this center part is raised, its diameter is at least 1 in. smaller than the inside diameter of the mating flange. When the center part is depressed, its diameter shall not be greater than the inside diameter of the mating flange. Machining of the depressed center is not required.

6.1.3 Flat Face Flanges. This Standard permits flat face flanges in all classes, either by providing flanges having the full thickness or the thickness with the raised face removed, without reduction of the pressure-temperature ratings subject to the following provisions.

6.1.3.1 The thickness of a Class 75, 150, or 300 flange from which the raised face has been removed shall be no less than the applicable *C* dimension of Tables 5, 6, 10, 11, and 12, minus 0.06 in.

6.1.3.2 The thickness of a flange of Class 400 or higher from which the raised face has been removed shall be no less than the applicable *C* dimension of Tables 7 to 9 and 13 to 15.

6.1.3.3 A gasket of Group Ia material in Annex B, Fig. B1, is recommended for all joints having two flat faced flanges using a gasket which has a larger diameter than those of the raised face.

6.1.3.4 The flange facing shall conform with para. 6.1.4 for the full width of seating of the gasket.

6.1.4 Flange Facing Finish. The finish of contact faces of pipe flanges shall be judged by visual comparison with Ra Standards (see ANSI/ASME B46.1) and not by instruments having stylus tracers and electronic amplification. The finishes required are given below. Other finishes may be furnished by agreement between user and manufacturer.

6.1.4.1 Ring-Joint. The side wall surface to gasket groove shall not exceed 63 μin. roughness.

6.1.4.2 Other Flange Facings. Either a serrated concentric or serrated spiral finish having a resultant surface finish from 125 μin. to 250 μin. average roughness shall be furnished. The cutting tool employed should have an approximate 0.06 in. or larger radius, and there should be from 45 grooves/in. through 55 grooves/in.

6.1.5 Flange Facing Finish Imperfections. Imperfections in the flange facing finish shall not exceed the dimensions shown in Table 16. Adjacent imperfections shall be separated by a distance of at least four times the maximum radial projection. A radial projection shall be measured by the difference between an outer radius and an inner radius encompassing the imperfection where the radii are struck from the centerline of the bore. Imperfections less than half the depth of the serrations shall not be considered cause for rejection. Protrusions above the serrations are not permitted.

6.2 Flange Bolt Holes

Bolt holes are in multiples of four. Bolt holes shall be equally spaced.

6.3 Spot Facing

All cast and forged steel flanges shall have bearing surfaces for bolting which shall be parallel to the flange face within 1 deg. Any back facing or spot facing required to accomplish parallelism shall not reduce the flange thickness *C* below the dimensions given in Tables 5 through 15. Any spot facing or back facing shall be in accordance with MSS SP-9.

6.4 Welding End Preparation for Welding Neck Flanges

6.4.1 Welding ends are shown in Figs. 1 through 7.

6.4.2 The contours of the outside of the welding neck beyond the welding groove are shown in Figs. 1, 2, 5, and 7.

6.4.3 Straight through bores shown in Figs. 1 and 2 are standard unless otherwise specifically ordered to suit the special conditions illustrated in Figs. 3, 4, 6, and 7.

6.4.4 Other welding end preparations furnished by agreement between purchaser and manufacturer do not invalidate compliance with this Standard.

6.5 Flange Bolting Dimensions

6.5.1 Stud-bolts threaded at both ends or full length, or bolts with hexagonal heads may be used. Dimensional recommendations for bolts, stud-bolts, and nuts are shown in Table 4. See para. 5.3 for bolting material.

6.5.2 For the method of calculating bolt lengths, see Annex C. The method of calculating bolt length is established for the convenience of industry to simplify the assembly of these parts on construction work, but

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:11 2005

users may select combinations of these bolt lengths to suit their needs. Hence, Annex C is not considered part of this Standard.

6.6 Gaskets for Line Flanges

6.6.1 Ring-joint gasket dimensions shall conform to ASME B16.20.

6.6.2 Nonmetallic gasket dimensions for Series A flanges with raised face shall conform to ASME B16.21.

6.6.3 Solid flat metal gaskets shall have contact width not greater than for Group III gaskets.

6.6.4 Spiral wound and double-jacketed corrugated metal gasket shall conform to ASME B16.20.

6.6.5 Nonmetallic gasket dimensions for Series B flanges with raised face shall have outside diameter equal to the raised face diameter and inside diameter equal to the nominal pipe size. If self-centering ring gaskets are used, the outside diameter shall equal the bolt circle diameter less one bolt hole diameter.

7 TOLERANCES[2]

7.1 General

For the purposes of determining conformance with this Standard, the convention for fixing significant digits where limits, maximum or minimum values are specified, shall be the rounding-off method defined in ASTM Practice E29. This requires that an observed or calculated value shall be rounded to the nearest unit in the last right-hand digit used for expressing the limit.

The listing of decimal tolerances does not imply a particular method of measurement.

7.2 Facings

7.2.1 Outside diameter, 0.06 in. raised face, 0.08 in.

7.2.2 Outside diameter, 0.25 in. raised face, 0.04 in.

7.2.3 Ring-joint groove tolerances are shown in Table 3.

[2] Unless otherwise stated, tolerances are equal, plus and minus.

7.3 Flange Thickness

Thickness, in.	
To 1.0	+0.12 in. −0
1.0–2.0	+0.19 in. −0
2.0–3.0	+0.31 in. −0
Over 3.0	+0.38 in. −0

7.4 Hub Dimensions Including Welding Ends

7.4.1 Nominal outside diameter of welding end of welding neck flanges (dimension *A* of Figs. 1 and 2).

+0.21 in.
−0.06 in.

7.4.2 Nominal inside diameter of welding ends of welding neck flanges (dimension *B* in the referenced Figures).

Figs. 1 and 2	+0.12 in. −0.06 in.
Fig. 3	+0 −0.06 in.

7.4.3 Bore of backing ring of welding neck flanges (dimension *C* of Figs. 3 and 4).

+0.010 in.
−0

7.4.4 Thickness of Hub. Regardless of tolerances specified for dimensions *A* and *B*, the thickness of hub at the welding end shall never be less than $87\frac{1}{2}\%$ of the nominal thickness of the pipe to which the flange is to be attached.

7.5 Overall Length Through Hub on Welding Neck Flanges

0.19 in.

7.6 Drilling and Facing

7.6.1 Bolt circle diameter, 0.06 in.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:12 2005

7.6.2 Center-to-center of adjacent bolt holes, 0.03 in.

7.6.3 Eccentricity between bolt circle diameter and machined facing diameters, 0.06 in.

8 TEST

8.1 Flange Testing

Flanges are not required to be hydrostatically tested.

		A 453-660	(10)		

GENERAL NOTE:
Bolting material shall not be used beyond temperature limits specified in the governing code.

NOTES:
(1) Repair welding of bolting material is prohibited.
(2) These bolting materials may be used with all listed materials and gaskets.
(3) These bolting materials may be used with all listed materials and gaskets, provided it has been verified that a sealed joint can be maintained under rated working pressure and temperature.
(4) These bolting materials may be used with all listed materials but are limited to Class 150 and Class 300 joints. See para. 5.4.1 for recommended gasket practices.
(5) This austenitic stainless material has been carbide solution treated but not strain hardened. Use A 194 nuts of corresponding material.
(6) This ferritic material is intended for low temperature service. Use A 194 Gr. 4 or Gr. 7 nuts.
(7) This austenitic stainless material has been carbide solution treated and strain hardened. Use A 194 nuts of corresponding material.
(8) This carbon steel fastener shall not be used above 400°F or below −20°F. See also Note (4). Bolts with drilled or undersized heads shall not be used.
(9) Acceptable nuts for use with quenched and tempered bolts are A 194 Gr. 2 and Gr. 2H. Mechanical property requirements for studs shall be the same as those for bolts.
(10) This special alloy is intended for high temperature service with austenitic stainless steel.
(11) ASME Boiler and Pressure Vessel Code, Section II materials, which also meet the requirements of the listed ASTM specifications, may also be used.

TABLE 2-2.2 RATINGS FOR GROUP 2.2 MATERIALS

Nominal Designation	Forgings	Castings	Plates
16Cr–12Ni–2Mo	A 182 Gr. F316 (1) A 182 Gr. F316H	A 351 Gr.CF3M (2) A 351 Gr. CF8M (1)	A 240 Gr. 316 (1) A 240 Gr. 316H
18Cr–13Ni–3Mo			A 240 Gr. 317 (1)
19Cr–10Ni–3Mo		A 351 Gr. CG8M (3)	

NOTES:
(1) At temperatures over 1000°F, use only when the carbon content is 0.04% or higher.
(2) Not to be used over 850°F.
(3) Not to be used over 1000°F.

TABLE 2-2.6 RATINGS FOR GROUP 2.6 MATERIALS

Nominal Designation	Forgings	Castings	Plates
25Cr–12Ni		A 351 Gr. CH8 (1) A 351 Gr. CH20 (1)(4)	
23Cr–12Ni			A 240 Gr. 309S (1)(2)(3) A 240 Gr. 309H

NOTES:
(1) At temperatures over 1000°F, use only when the carbon content is 0.04% or higher.
(2) For temperatures above 1000°F, use only if the material is heat treated by heating it to a temperature of at least 1900°F and quenching in water or rapidly cooling by other means.
(3) This material should be used for service temperatures 1050°F and above only when assurance is provided that grain size is not finer than ASTM 6.
(4) For service temperatures above 850°F, it is recommended that killed steel containing not less than 0.10% residual silicon be used.

Tolerances	
E (depth)	+0.016 −0
F (width)	±0.008
P (pitch diameter)	±0.005
R (radius at bottom)	Max.
23 deg. (angle)	±½ deg.

GENERAL NOTES:

(a) Dimensions are in inches.

(b) Ring-joint gaskets are not contemplated for NPS 38 and larger flanges.

NOTES:

(1) Height of raised portion is equal to the depth of groove dimension *E*, but is not subjected to the tolerances for *E*. Full face contour may be used.

(2) For facing requirements for flanges, see para. 6.1.1.

(3) See para. 4.1.7 for marking requirements.

WELDING ENDS
(Welding Neck Flanges, No Backing Rings)

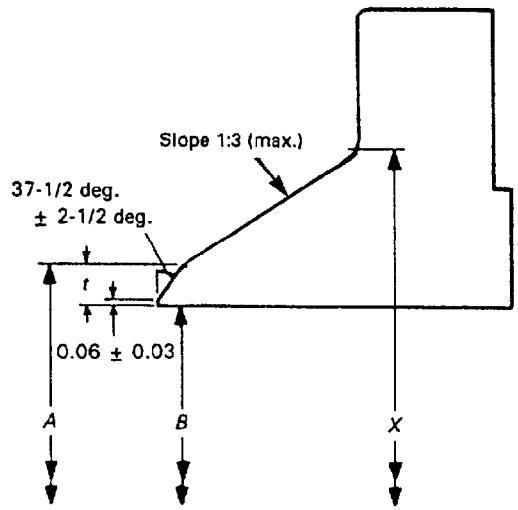

FIG. 1 BEVEL FOR WALL THICKNESSES *t* FROM 0.19 in. TO 0.88 in., INCLUSIVE[1-3]

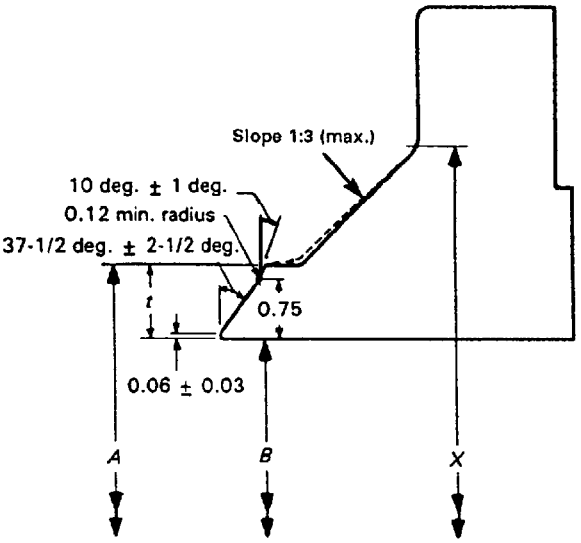

FIG. 2 BEVEL FOR WALL THICKNESSES *t* GREATER THAN 0.88 in.[1-3]

A = nominal outside diameter of pipe, in.
B = nominal inside diameter of pipe, in.
t = nominal wall thickness of pipe, in.

NOTES:

(1) See paras. 6.4 and 7.4 for details and tolerances.

(2) See Figs. 3 and 4 for additional details of welding ends.

(3) When the thickness of the hub at the bevel is greater than that of the pipe to which the flange is joined, and the additional thickness is provided on the outside diameter, a taper weld having a slope not exceeding 1 to 3 may be employed or, alternatively, the greater outside diameter may be tapered, at the same maximum slope or less, from a point on the welding bevel equal to the O.D. of the mating pipe. Similarly, when the greater thickness is provided on the inside of the flange, it shall be taper bored from the welding end at a slope not exceeding 1 to 3.

When flanges covered by this Standard are intended for services with light wall and higher strength pipe, the thickness of the hub at the bevel may be greater than that of the pipe to which the flange is joined. Under these conditions a single taper hub may be provided and the outside diameter of the hub at the base (dimension *X*) may also be modified.

The additional thickness may be provided on either inside or outside or partially on each side, but the total additional thickness shall not exceed one-half times the nominal wall thickness of intended mating pipe. See Figs. 5, 6, and 7.

WELDING ENDS
(Welding Neck Flanges With Backing Rings)

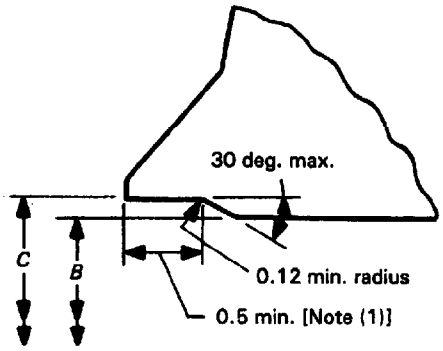

FIG. 3 INSIDE CONTOUR FOR USE WITH RECTANGULAR BACKING RING[1-3]

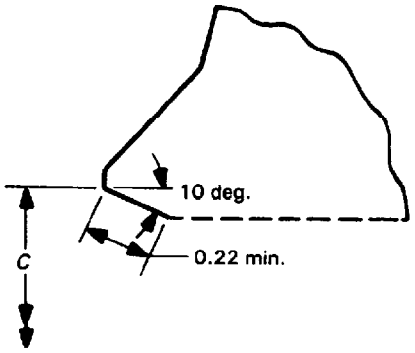

FIG. 4 INSIDE CONTOUR FOR USE WITH TAPER BACKING RING[1-3]

A = nominal outside diameter of welding end, in.
B = nominal inside diameter of pipe
= $A - 2t$, in.
C = $A - 0.031 - 1.75t - 0.010$ in.
t = nominal wall thickness of pipe, in.
0.031 = minus tolerance on O.D. of pipe, in.
$1.75t$ = 87½% of nominal wall multiplied by two to convert into terms of diameter
0.010 = plus tolerance on diameter C, in. (see para. 7.4.3.)

NOTES:
(1) 0.5 in. depth based on use of 0.75 in. wide backing ring.
(2) See paras. 6.4 and 7.4 for details and tolerances.
(3) See Figs. 1 and 2 for welding end details of welding neck flanges.

WELDING ENDS
(Welding Neck Flanges)

ADDITIONAL THICKNESS FOR WELDING TO HIGHER STRENGTH PIPE

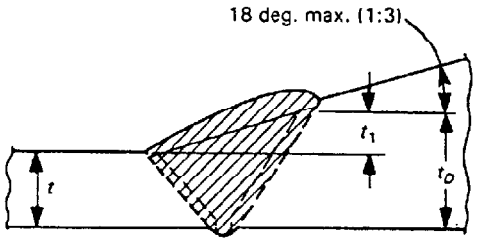

FIG. 5 BEVEL FOR OUTSIDE THICKNESS[1-3]

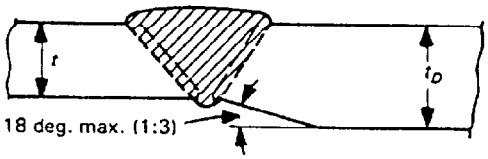

FIG. 6 BEVEL FOR INSIDE THICKNESS[1-3]

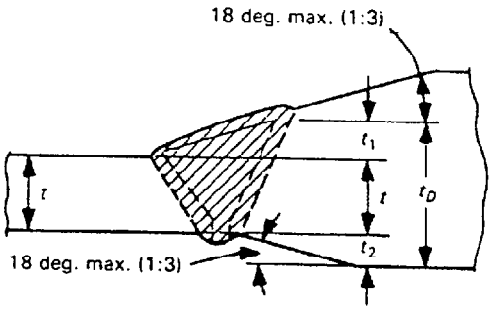

FIG. 7 BEVEL FOR COMBINED THICKNESS[1-3]

NOTES:

(1) Neither t_1, t_2, nor their sum ($t_1 + t_2$) shall exceed $0.5t$.

(2) When the minimum specified yield strengths of the sections to be joined are unequal, the value of t_D shall at least equal t times the ratio of minimum specified yield strength of the pipe to yield strength of the flange.

(3) Welding shall be in accordance with the applicable code.

Notes to Tables 5–15

GENERAL NOTE: Dimensions are in inches.

NOTES:
(1) For tolerances, see Section 7.
(2) For facings, see para. 6.1.
(3) For flange bolt holes, see para. 6.2.
(4) For spot facing, see para. 6.3.
(5) The bore is to be specified by the purchaser. Tolerances in para. 7.4.2 apply.
(6) Blind flanges may be made with or without hubs at the manufacturer's option.
(7) When these flanges are required with flat face, either the full thickness or thickness with raised face removed may be furnished. Users are reminded that removing the raised face will make the length through hub nonstandard.
(8) This dimension is for the large end of hub, which may be straight or tapered.
(9) For welding and bevel, see para. 6.4.
(10) Dimensions for Classes 400, 600, and 900 NPS 38 and larger for Series B flanges are the same as for the Series A flanges.

ANNEX A
METHODS FOR ESTABLISHING PRESSURE-TEMPERATURE RATINGS

(This Annex is not part of ASME B16.47-1996 and is included for information only.)

A1 GENERAL

A1.1 Introduction

Pressure–temperature ratings in this Standard have been determined by the procedures in this Annex.

The primary consideration in establishing ratings is adequate wall thickness to sustain stresses due to pressure and other loadings. Other considerations affecting or limiting the ratings include:

(a) stresses in flanges resulting from bolt-up necessary to maintain gasket seal;

(b) distortion of flanges due to loadings transmitted through the pipeline; and

(c) limitations applying primarily to valves but imposed also on flanges in order to maintain compatible ratings.

A1.2 Material Groups

Material groups in Table 1 are based on identical or closely matched allowable stress and yield strength values. Where they are not identical, the lower value has been applied.

Note that material groups are not numbered consecutively. Some groups are intended for use only in valves. See ASME B16.34.

A1.3 Material Properties

The allowable stress and yield strength values used to calculate the pressure–temperature ratings were taken from the ASME Boiler and Pressure Vessel Code, Section II, Part D. In addition, data has been provided directly by the ASME Boiler and Pressure Vessel Subcommittee on Materials.

A2 RATINGS

A2.1 Rating Equation

Ratings given in Tables 2, psig at temperatures expressed in degrees Fahrenheit, for all materials and pressure classes, are established by Eq. (1):

$$P_T = P_r S_1/8750 \le P_c \qquad (1)$$

where

P_t = rated working pressure, psig, for the specified material at temperature T

P_r = pressure rating class index expressed in psi[1] (e.g. P_r = 300 psi for Class 300)

S_1 = selected stress, psi, for the specified material at temperature T (see paras. A2.2, A2.3, and A2.4)

P_c = ceiling pressure, psig, as specified in A3 at temperature T

A2.2 Ratings for Group 1 Materials, Class 300 and Higher

The selected stress S_1 fore each material group among Group 1 materials in Table 1A is determined as follows.

(a) At temperatures below the creep range, S_1 shall be lowest of the following values:

(1) 60% of specified minimum yield strength at 100°F;

(2) 60% of the yield strength at temperature T;

(3) 1.25 times the alowable stress at temperature T as listed for ASME BPV Code, Section I, or, if not listed for Section I, as listed for Section VIII Division 1.

(b) At temperatures in the creep range (defined as those above 700°F for Group 1 materials), S_1 shall be the lowest of the following values:

(1) 60% of the yield strength at temperature T;

(2) the allowable stress at temperature T as listed

[1]This definition of P_r does not apply to Class 75 and Class 150. See para. A2.4.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:53:25 2005

for ASME BPV Code, Section I, or, if not listed for Section I, as listed for Section VIII, Division 1.

(c) In no case shall the value of S_1 increase with increasing temperature.

(d) Yield strength values for determination of values of S_1 shall be obtained from ASME BPV Code, Section II, Part D.

(e) Where more than one allowable stress value is listed for a material at any temperature, the lower value shall be used. If lower allowable stress values do not appear, and it is noted in the allowable stress table that the allowable stress values exceed two-thirds of the yield strength at temperature, then the allowable stress values shall be determined as two-thirds of the tabulated yield strength at temperature.

(f) Allowable stress values listed for the ASME BPV Code, Section III, Class 2 and Class 3 may be used only if the material is not listed for either Section I or Section VIII, Division 1.

A2.3 Ratings for Group 2 Materials, Class 300 and Higher

The selected stress S_1, for each material group among Group 2 materials in Table 1A is determined as follows.

(a) At temperatures below the creep range, S_1 is determined in accordance with para. A2.2(a), except that 70% of yield strength shall be used, instead of 60%, in paras. A2.2(a)(1) and (a)(2).

(b) At temperatures in the creep range (defined as those above 950°F for Group 2 materials), S_1 is determined in accordance with para. A2.2(b).

(c) The limitations in paras. A2.2(c), (d), (e), and (f) apply.

A2.4 Ratings for Classes 75 and 150, All Material Groups

Pressure–temperature ratings for Classes 75 and 150 flanges are determined for each material group as set forth in paras. A2.1, A2.2, and A2.3 with the following exceptions.

(a) The value of P_r in Eq. (1) (para A2.1) shall be 57.5 psi for Class 75 and 115 psi for Class 150.

(b) The value for S_1 shall be in accordance with the requirements of paras. A2.1, A2.2, and A2.3.

(c) The value for P_T in Eq. (1) at temperature T (degrees Fahrenheit) shall not exceed that given by Eqs. (2) and (3).

For Class 75

$$P_T = 160 - 0.15T \quad (2)$$

For Class 150

$$P_T = 320 - 0.3T \quad (3)$$

The limits of T in equation (2) and (3) are 100°F min. and 1000°F max. For values of T less than 100°F, T equal to 100°F is used.

A3 MAXIMUM RATINGS

A3.1 Maximum Ratings

A set of maximum or ceiling pressure–temperature ratings, P_c, are shown in Table A1. They are imposed to limit deflections.

ANNEX B

GASKETS
(Other Than Ring-Joint)

(This Annex is an integral part of ASME B16.47-1996 and is placed after the main text for convenience.)

B1 SCOPE

This Annex covers gasket characteristics.

B2 GASKET MATERIALS AND CONSTRUCTION

Classification of gasket materials and types is shown in Fig. B1. Other gaskets, which result in no increase in bolt loads or flange moment over those resulting from the gaskets included in the respective groups in this Appendix, may be used and warrant the ratings of this Standard with the limiting dimensions of the applicable group. See also para. 5.4 for application of gaskets.

B3 GASKET DIMENSIONS

(a) The actual dimensions of a gasket must be established by the user. Reference to a dimensional standard for gaskets, such as ASME B16.21 and ASME B16.20 is recommended. In any case, selected dimensions should be based on the type of gasket and its characteristics. These characteristics include its density, flexibility, resistance to the fluid and its temperature, and the necessity for satisfactorily compressing the gasket on its I.D., its O.D., or both. Also to be considered is the question of allowing a "pocket" at the gasket I.D. (between the flange facings) or of allowing any intrusion of the gasket into the flange bore. Consideration should be given to the service fluid as well as to the possibility of damage which might result from partially disintegrated gaskets.

(b) Gaskets are divided into three groups based on their gasket loading factors as shown in the ASME BPV Code, Section VIII, Division 1, Pressure Vessels.

ANNEX C
METHOD FOR CALCULATING BOLT LENGTHS

(This Annex is not part of ASME B16.47-1996 and is included for information only. See para. 6.5.2.)

The following formulas [see Note (1)] may be used to establish bolt lengths.

$$L_{CSB} = A + n$$

where

A = $2(C + t + d) + G + F$ (i.e., stud-bolt length exclusive of negative length tolerance n)
C = minimum flange thickness [see Tables 5 through 15 and Note (2) below]
F = total height of facings of depth of ring-joint groove for both flanges (see Table C1)
G = 0.12 in. gasket thickness for raised face
L_{CSB} = calculated stud-bolt length (effective thread length, excluding end points)
L_{SSB} = specified stud-bolt length (effective thread length, excluding end points), which is L_{CSB} rounded off to the nearest practical increment (see Fig. C1)
d = heavy nut thickness (equals nominal bolt diameter, see ASME/ANSI B18.2.2)
n = negative tolerance on bolt length (see Table C2)
t = plus tolerance for flange thickness (see para. 7.2)

NOTES:

(1) The equations used in this Annex are for calculated bolt lengths established to assure full thread engagement of heavy hexagon nuts when worst case tolerances occur on all relevant dimensions of the flanged joint. The use of shorter bolt lengths is acceptable provided that full thread engagement is obtained at assembly (see para. 6.5.2)

(2) 0.06 in. raised face is included in minimum flange thickness for Classes 75, 150, and 300 flanges.

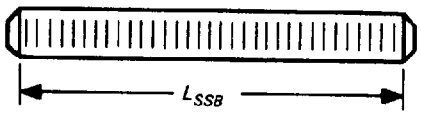

FIG. C1 SPECIFIED STUD-BOLT LENGTH

Data for Length Calculations
TABLE C1 *F* VALUES

Flanged Joint Class	Total Height of Facings or Depth of Ring-Joint Groove for Both Flanges, *F*		
	Type of Flange Facing		
	0.06 in. Raised	0.25 in. Raised	Ring-Joint
150 and 300	Zero [Note (1)]	0.50 in.	2 × groove depth
400 to 2500	0.12 in.	0.50 in.	2 × groove depth

NOTE:
(1) Raised face (0.06 in.) is included in minimum flange thickness for Classes 75, 150, and 300 flanges.

TABLE C2 *n* VALUES

Length		Negative Tolerance on Bolt Lengths, *n*
Stud-bolt	A	0.06 in. for lengths up to 12 in., incl. 0.12 in. for lengths over 12 in. to 18 in., incl. 0.25 in. for lengths over 18 in.

ANNEX D
QUALITY SYSTEM PROGRAM

(This Annex is an integral part of ASME B16.47.1996 and is placed after the main text for convenience.)

The products manufactured in accordance with this Standard shall be produced under a quality system program following the principles of an appropriate standard from the ISO 9000 series.[1] A determination of the need for registration and/or certification of the product manufacturer's quality system program by an independent organization shall be the responsibility of the manufacturer. The detailed documentation demonstrating program compliance shall be available to the purchaser at the manufacturer's facility. A written summary description of the program utilized by the product manufacturer shall be available to the purchaser upon request. The product manufacturer is defined as the entity whose name or trademark appears on the product in accordance with the marking or identification requirements of this Standard.

[1]The series is also available from the American National Standards Institute (ANSI) and the American Society for Quality Control (ASQC) as American National Standards that are identified by a prefix "Q" replacing the prefix "ISO". Each standard of the series is listed under Annex E.

ADOPTION NOTICE

ASME-B31.1, "Piping, Power," was adopted on October 3, 1994 for use by the Department of Defense (DoD). Proposed changes by DoD activities must be submitted to the DoD Adopting Activity: Commanding Officer, Naval Construction Battalion Center, Code 156, 1000 23rd Avenue, Port Hueneme, CA 93043-4301. DoD activities may obtain copies of this standard from the Standardization Document Order Desk, 700 Robbins Avenue, Building 4D, Philadelphia, PA 19111-5094. The private sector and other Government agencies may purchase copies from the American Society of Mechanical Engineers, 345 East 47th Street, New York, NY 10017.

Wed Feb 02 00:53:58 2005

Date of Issuance: December 10, 2001
Mandatory Date: June 10, 2002

This Edition was approved by the American National Standards Institute and designated ASME B31.1-2001 on July 2, 2001

The 2001 Edition of this Code is being issued with an automatic update service that includes Addenda, Interpretations, and Cases. The next Edition is scheduled for publication in 2004.

The use of Addenda allows revisions made in response to public review comments or committee actions to be published on a regular basis; revisions published in Addenda will become effective 6 months after the Date of Issuance of the Addenda.

ASME issues written replies to inquiries concerning interpretations of technical aspects of the Code. The Interpretations are published in a separate supplement.

Periodically certain actions of the ASME B31 Committee will be published as Cases. While these Cases do not constitute formal revisions of the Code, they may be used in specifications, or otherwise, as representing considered opinions of the Committee. The Cases are published in a separate supplement.

The user of the Code will note that metric equivalents of U.S. Customary units appear throughout this issue of the Code (except for Appendix II). The values stated in U.S. Customary units are to be regarded as standard.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment which provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable Letters Patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations issued in accordance with governing ASME procedures and policies which preclude the issuance of interpretations by individual volunteers.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

FOREWORD

The general *philosophy* underlying this Power Piping Code is to parallel those provisions of Section I, Power Boilers, of the ASME Boiler and Pressure Vessel Code, as they can be applied to power piping systems. The Allowable Stress Values for power piping are generally consistent with those assigned for power boilers. This Code is more conservative than some other piping codes, reflecting the need for long service life and maximum reliability in power plant installations.

The Power Piping Code as currently written does not differentiate between the design, fabrication, and erection requirements for *critical and noncritical piping systems,* except for certain stress calculations and mandatory nondestructive tests of welds for heavy wall, high temperature applications. The *problem involved* is to try to reach agreement on how to evaluate criticality, and to avoid the inference that noncritical systems do not require competence in design, fabrication, and erection. Some day such levels of quality may be definable, so that the need for the many different piping codes will be overcome.

There are many instances where the Code serves to *warn a designer,* fabricator, or erector against possible pitfalls; but the Code is *not a handbook,* and cannot substitute for education, experience, and sound engineering judgment.

Nonmandatory Appendices are included in the Code. Each contains information on a specific subject, and is maintained current with the Code. Although written in mandatory language, these Appendices are offered for application at the user's discretion.

The Code *never intentionally puts a ceiling limit on conservatism.* A designer is free to specify more rigid requirements as he feels they may be justified. *Conversely, a designer who is capable* of a more rigorous analysis than is specified in the Code may justify a less conservative design, and still satisfy the basic intent of the Code.

The Power Piping Committee strives to keep abreast of the current technological improvements in new materials, fabrication practices, and testing techniques; and endeavors to keep the Code updated to permit the use of acceptable new developments.

INTRODUCTION

The ASME B31 Code for Pressure Piping consists of a number of individually published Sections, each an American National Standard, under the direction of ASME Committee B31, Code for Pressure Piping.

Rules for each Section have been developed considering the need for application of specific requirements for various types of pressure piping. Applications considered for each Code Section include:

B31.1 Power Piping: piping typically found in electric power generating stations, in industrial and institutional plants, geothermal heating systems, and central and district heating and cooling systems;

B31.3 Process Piping: piping typically found in petroleum refineries, chemical, pharmaceutical, textile, paper, semiconductor, and cryogenic plants, and related processing plants and terminals;

B31.4 Pipeline Transportation Systems for Liquid Hydrocarbons and Other Liquids: piping transporting products which are predominately liquid between plants and terminals and within terminals, pumping, regulating, and metering stations;

B31.5 Refrigeration Piping: piping for refrigerants and secondary coolants;

B31.8 Gas Transportation and Distribution Piping Systems: piping transporting products which are predominately gas between sources and terminals, including compressor, regulating, and metering stations; and gas gathering pipelines;

B31.9 Building Services Piping: piping typically found in industrial, institutional, commercial, and public buildings, and in multi-unit residences, which does not require the range of sizes, pressures, and temperatures covered in B31.1;

B31.11 Slurry Transportation Piping Systems: piping transporting aqueous slurries between plants and terminals and within terminals, pumping, and regulating stations.

This is the B31.1 Power Piping Code Section. Hereafter, in this Introduction and in the text of this Code Section B31.1, where the word *Code* is used without specific identification, it means this Code Section.

It is the owner's responsibility to select the Code Section which most nearly applies to a proposed piping installation. Factors to be considered by the owner include: limitations of the Code Section; jurisdictional requirements; and the applicability of other codes and standards. All applicable requirements of the selected Code Section shall be met. For some installations, more than one Code Section may apply to different parts of the installation. The owner is also responsible for imposing requirements supplementary to those of the selected Code Section, if necessary, to assure safe piping for the proposed installation.

Certain piping within a facility may be subject to other codes and standards, including but not limited to:

ASME Boiler and Pressure Vessel Code, Section III: nuclear power piping;

ANSI Z223.1 National Fuel Gas Code: piping for fuel gas from the point of delivery to the connection of each fuel utilization device;

NFPA Fire Protection Standards: fire protection systems using water, carbon dioxide, halon, foam, dry chemical, and wet chemicals;

NFPA 99 Health Care Facilities: medical and laboratory gas systems;

NFPA 8503 Standard for Pulverized Fuel Systems: piping for pulverized coal from the coal mills to the burners;

Building and plumbing codes, as applicable, for potable hot and cold water, and for sewer and drain systems.

The Code sets forth engineering requirements deemed necessary for safe design and construction of pressure piping. While safety is the basic consideration, this factor alone will not necessarily govern the final specifications for any piping system. The designer is cautioned that the Code is not a design handbook; it does not do away with the need for the designer or for competent engineering judgment.

To the greatest possible extent, Code requirements for design are stated in terms of basic design principles and formulas. These are supplemented as necessary with specific requirements to assure uniform application of principles and to guide selection and application of piping elements. The Code prohibits designs and practices known to be unsafe and contains warnings where caution, but not prohibition, is warranted.

The specific design requirements of the Code usually revolve around a simplified engineering approach to a subject. It is intended that a designer capable of applying

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:01 2005

more complete and rigorous analysis to special or unusual problems shall have latitude in the development of such designs and the evaluation of complex or combined stresses. In such cases the designer is responsible for demonstrating the validity of his approach.

This Code Section includes:

(1) references to acceptable material specifications and component standards, including dimensional requirements and pressure-temperature ratings;

(2) requirements for design of components and assemblies, including pipe supports;

(3) requirements and data for evaluation and limitation of stresses, reactions, and movements associated with pressure, temperature changes, and other forces;

(4) guidance and limitations on the selection and application of materials, components, and joining methods;

(5) requirements for the fabrication, assembly, and erection of piping; and

(6) requirements for examination, inspection, and testing of piping.

It is intended that this Edition of Code Section B31.1 and any subsequent Addenda not be retroactive. Unless agreement is specifically made between contracting parties to use another issue, or the regulatory body having jurisdiction imposes the use of another issue, the latest Edition and Addenda issued at least 6 months prior to the original contract date for the first phase of activity covering a piping system or systems shall be the governing document for all design, materials, fabrication, erection, examination, and testing for the piping until the completion of the work and initial operation.

Users of this Code are cautioned against making use of revisions without assurance that they are acceptable to the proper authorities in the jurisdiction where the piping is to be installed.

Code users will note that clauses in the Code are not necessarily numbered consecutively. Such discontinuities result from following a common outline, insofar as practicable, for all Code Sections. In this way, corresponding material is correspondingly numbered in most Code Sections, thus facilitating reference by those who have occasion to use more than one Section.

The Code is under the direction of ASME Committee B31, Code for Pressure Piping, which is organized and operates under procedures of The American Society of Mechanical Engineers which have been accredited by the American National Standards Institute. The Committee is a continuing one, and keeps all Code Sections current with new developments in materials, construction, and industrial practice. Addenda are issued periodically. New editions are published at intervals of three to five years.

When no Section of the ASME Code for Pressure Piping, specifically covers a piping system, at his discretion the user may select any Section determined to be generally applicable. However, it is cautioned that supplementary requirements to the Section chosen may be necessary to provide for a safe piping system for the intended application. Technical limitations of the various Sections, legal requirements, and possible applicability of other codes or standards are some of the factors to be considered by the user in determining the applicability of any Section of this Code.

The Committee has established an orderly procedure to consider requests for interpretation and revision of Code requirements. To receive consideration, inquiries must be in writing and must give full particulars (see Mandatory Appendix H covering preparation of technical inquiries). The Committee will not respond to inquiries requesting assignment of a Code Section to a piping installation.

The approved reply to an inquiry will be sent directly to the inquirer. In addition, the question and reply will be published as part of an Interpretation Supplement issued to the applicable Code Section.

A Case is the prescribed form of reply to an inquiry when study indicates that the Code wording needs clarification or when the reply modifies existing requirements of the Code or grants permission to use new materials or alternative constructions. Proposed Cases are published in *Mechanical Engineering* for public review. In addition, the Case will be published as part of a Case Supplement issued to the applicable Code Section.

A case is normally issued for a limited period after which it may be renewed, incorporated in the Code, or allowed to expire if there is no indication of further need for the requirements covered by the Case. However, the provisions of a Case may be used after its expiration or withdrawal, provided the Case was effective on the original contract date or was adopted before completion of the work; and the contracting parties agree to its use.

Materials are listed in the Stress Tables only when sufficient usage in piping within the scope of the Code has been shown. Materials may be covered by a Case. Requests for listing shall include evidence of satisfactory usage and specific data to permit establishment of allowable stresses, maximum and minimum temperature limits, and other restrictions. Additional criteria can be found in the guidelines for addition of new materials

in the ASME Boiler and Pressure Vessel Code, Section II and Section VIII, Division 1, Appendix B. (To develop usage and gain experience, unlisted materials may be used in accordance with Para. 123.1.)

Requests for interpretation and suggestions for revision should be addressed to the Secretary, ASME B31 Committee, Three Park Avenue, New York, NY 10016-5990.

CHAPTER I
SCOPE AND DEFINITIONS

100 GENERAL

This Power Piping Code is one of several Sections of the American Society of Mechanical Engineers Code for Pressure Piping, B31. This Section is published as a separate document for convenience.

Standards and specifications specifically incorporated by reference into this Code are shown in Table 126.1. It is not considered practical to refer to a dated edition of each of the standards and specifications in this Code. Instead, the dated edition references are included in an Addenda which will be revised yearly.

100.1 Scope

Rules for this Code Section have been developed considering the needs for applications which include piping typically found in electric power generating stations, in industrial and institutional plants, geothermal heating systems, and central and district heating and cooling systems.

100.1.1 This Code prescribes requirements for the design, materials, fabrication, erection, test, and inspection of piping systems.

Piping as used in this Code includes pipe, flanges, bolting, gaskets, valves, relief devices, fittings, and the pressure containing portions of other piping components, whether manufactured in accordance with Standards listed in Table 126.1 or specially designed. It also includes hangers and supports and other equipment items necessary to prevent overstressing the pressure containing components.

Rules governing piping for miscellaneous appurtenances, such as water columns, remote water level indicators, pressure gages, gage glasses etc., are included within the scope of this Code, but the requirements for boiler appurtenances shall be in accordance with Section I of the ASME Boiler and Pressure Vessel Code, PG-60.

The users of this Code are advised that in some areas legislation may establish governmental jurisdiction over the subject matter covered by this Code. However, any such legal requirement shall not relieve the owner of his inspection responsibilities specified in para. 136.1.

100.1.2 Power piping systems as covered by this Code apply to all piping and their component parts except as excluded in para. 100.1.3. They include but are not limited to steam, water, oil, gas, and air services. 01

(A) This Code covers boiler external piping as defined below for power boilers and high temperature, high pressure water boilers in which: steam or vapor is generated at a pressure of more than 15 psig [100 kPa (gage)]; and high temperature water is generated at pressures exceeding 160 psig [1103 kPa (gage)] and/or temperatures exceeding 250°F (120°C).

Boiler external piping shall be considered as that piping which begins where the boiler proper terminates at:

(1) the first circumferential joint for welding end connections; or

(2) the face of the first flange in bolted flanged connections; or

(3) the first threaded joint in that type of connection; and which extends up to and including the valve or valves required by para. 122.1.

The terminal points themselves are considered part of the boiler external piping. The terminal points and piping external to power boilers are illustrated by Figs. 100.1.2(A), 100.1.2(B), and 100.1.2(C).

Piping between the terminal points and the valve or valves required by para. 122.1 shall be provided with Data Reports, inspection, and stamping as required by Section I of the ASME Boiler and Pressure Vessel Code. All welding and brazing of this piping shall be performed by manufacturers or contractors authorized to use the appropriate symbol shown in Figs. PG-105.1 through PG-105.3 of Section I of the ASME Boiler and Pressure Vessel Code. The installation of boiler external piping by mechanical means may be performed by an organization not holding a Code symbol stamp. However, the holder of a valid S, A, or PP Certificate of Authorization shall be responsible for the documentation and hydrostatic test, regardless of the method of assembly. The quality control system requirements of

Administrative Jurisdiction and Technical Responsibility

——— Boiler Proper — The ASME Boiler and Pressure Vessel Code (ASME BPVC) has total administrative jurisdiction and technical responsibility. Refer to ASME BPVC Section 1 Preamble.

●——— Boiler External Piping and Joint (BEP) — The ASME BPVC has total administrative jurisdiction (mandatory certification by Code Symbol stamping, ASME Data Forms, and Authorized Inspection) of BEP. The ASME Section Committee B31.1 has been assigned technical responsibility. Refer to ASME BPVC Section I Preamble and ASME B31.1 Scope, para. 100.1.2(A). Applicable ASME B31.1 Editions and Addenda are referenced in ASME BPVC Section I, PG-58.3.

o– – – – Nonboiler External Piping and Joint (NBEP) — The ASME Code Committee for Pressure Piping, B31, has total administrative and technical responsibility.

FIG. 100.1.2(C) CODE JURISDICTIONAL LIMITS FOR PIPING — SPRAY TYPE DESUPERHEATER

Section I of the ASME Boiler and Pressure Vessel Code shall apply. These requirements are shown in Appendix J of this Code.

The valve or valves required by para. 122.1 are part of the boiler external piping, but do not require ASME Boiler and Pressure Vessel Code, Section I inspection and stamping except for safety, safety relief, and relief valves, see para. 107.8.2. Refer to PG-11.

Pipe connections meeting all other requirements of this Code but not exceeding NPS ½ may be welded to pipe or boiler headers without inspection and stamping required by Section I of the ASME Boiler and Pressure Vessel Code.

Nonboiler external piping includes all the piping covered by this Code except for that portion defined above as boiler external piping.

100.1.3 This Code does not apply to the following:

(A) economizers, heaters, pressure vessels, and components covered by Sections of the ASME Boiler and Pressure Vessel Code;

(B) building heating and distribution steam and condensate piping designed for 15 psig [100 kPa(gage)] or less, or hot water heating systems designed for 30 psig [200 kPa (gage)] or less; 01

(C) piping for hydraulic or pneumatic tools and their

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:04 2005

components downstream of the first block or stop valve off the system distribution header;

(D) piping for marine or other installations under Federal control;

(E) towers, building frames, tanks, mechanical equipment, instruments, and foundations;

100.2 Definitions

Some commonly used terms relating to piping are defined below. Terms related to welding generally agree with AWS A3.0. Some welding terms are defined with specified reference to piping. For welding terms used in this Code, but not shown here, definitions of AWS A3.0 apply.

anchor: a rigid restraint providing substantially full fixation, permitting neither translatory nor rotational displacement of the pipe.

annealing: see *heat treatments.*

arc welding: a group of welding processes wherein coalescence is produced by heating with an electric arc or arcs, with or without the application of pressure and with or without the use of filler metal.

assembly: the joining together of two or more piping components by bolting, welding, caulking, brazing, soldering, cementing, or threading into their installed location as specified by the engineering design.

automatic welding: welding with equipment which performs the entire welding operation without constant observation and adjustment of the controls by an operator. The equipment may or may not perform the loading and unloading of the work.

backing ring: backing in the form of a ring that can be used in the welding of piping.

ball joint: a component which permits universal rotational movement in a piping system.

base metal: the metal to be welded, brazed, soldered, or cut.

branch connection: the attachment of a branch pipe to the run of a main pipe with or without the use of fittings.

braze welding: a method of welding whereby a groove, fillet, plug, or slot weld is made using a nonferrous filler metal having a melting point below that of the base metals, but above 800°F (425°C). The filler metal is not distributed in the joint by capillary action. (Bronze welding, formerly used, is a misnomer for this term.)

brazing: a metal joining process wherein coalescence is produced by use of a nonferrous filler metal having a melting point above 800°F (425°C) but lower than that of the base metals joined. The filler metal is distributed between the closely fitted surfaces of the joint by capillary action.

butt joint: a joint between two members lying approximately in the same plane.

component: component as used in this Code is defined as consisting of but not limited to items such as pipe, piping subassemblies, parts, valves, strainers, relief devices, fittings, etc.

standard component: a component manufactured in accordance with one or more of the standards listed in Table 126.1.

specially designed component: a component designed in accordance with para. 104.7.2.

defect: a flaw (imperfection or unintentional discontinuity) of such size, shape, orientation, location, or properties as to be rejectable.

discontinuity: a lack of continuity or cohesion; an interruption in the normal physical structure of material or a product.

employer: the owner, manufacturer, fabricator, contractor, assembler, or installer responsible for the welding, brazing, and NDE performed by his organization including procedure and performance qualifications.

engineering design: the detailed design developed from process requirements and conforming to Code requirements, including all necessary drawings and specifications, governing a piping installation.

equipment connection: an integral part of such equipment as pressure vessels, heat exchangers, pumps, etc., designed for attachment of pipe or piping components.

erection: the complete installation of a piping system, including any field assembly, fabrication, testing, and inspection of the system.

examination: denotes the procedures for all nondestructive examination. Refer to para. 136.1 and the definition for visual examination.

expansion joint: a flexible piping component which absorbs thermal and/or terminal movement.

fabrication: primarily, the joining of piping components into integral pieces ready for assembly. It includes bending, forming, threading, welding, or other opera-

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:04 2005

tions upon these components, if not part of assembly. It may be done in a shop or in the field.

face of weld: the exposed surface of a weld on the side from which the welding was done.

filler metal: metal to be added in welding, soldering, brazing, or braze welding.

fillet weld: a weld of approximately triangular cross section joining two surfaces approximately at right angles to each other in a lap joint, tee joint, corner joint, or socket weld.

fire hazard: situation in which a material of more than average combustibility or explosibility exists in the presence of a potential ignition source.

flaw: an imperfection or unintentional discontinuity which is detectable by a nondestructive examination.

full fillet weld: a fillet weld whose size is equal to the thickness of the thinner member joined.

fusion: the melting together of filler metal and base metal, or of base metal only, which results in coalescence.

gas welding: a group of welding processes wherein coalescence is produced by heating with a gas flame or flames, with or without the application of pressure, and with or without the use of filler metal.

groove weld: a weld made in the groove between two members to be joined.

heat affected zone: that portion of the base metal which has not been melted, but whose mechanical properties or microstructure have been altered by the heat of welding or cutting.

heat treatments

annealing, full: heating a metal or alloy to a temperature above the critical temperature range and holding above the range for a proper period of time, followed by cooling to below that range. (A softening treatment is often carried out just below the critical range which is referred to as a subcritical anneal.)

normalizing: a process in which a ferrous metal is heated to a suitable temperature above the transformation range and is subsequently cooled in still air at room temperature.

postweld heat treatment: any heat treatment subsequent to welding.

preheating: the application of heat to a base metal immediately prior to a welding or cutting operation.

stress-relieving: uniform heating of a structure or portion thereof to a sufficient temperature to relieve the major portion of the residual stresses, followed by uniform cooling.

imperfection: a condition of being imperfect; a departure of a quality characteristic from its intended condition.

indication: the response or evidence from the application of a nondestructive examination.

inert gas metal arc welding: an arc welding process wherein coalescence is produced by heating with an electric arc between a metal electrode and the work. Shielding is obtained from an inert gas, such as helium or argon. Pressure may or may not be used and filler metal may or may not be used.

inspection: denotes verifying the performance of examination and tests by an Inspector.

joint design: the joint geometry together with the required dimensions of the welded joint.

joint penetration: the minimum depth of a groove weld extends from its face into a joint, exclusive of reinforcement.

low energy capacitor discharge welding: a resistance welding process wherein coalescence is produced by the rapid discharge of stored electric energy from a low voltage electrostatic storage system.

manual welding: welding wherein the entire welding operation is performed and controlled by hand.

maximum allowable stress: the maximum stress value that may be used in the design formulas for a given material and design temperature.

maximum allowable working pressure (MAWP): the pressure at the coincident temperature to which a boiler or pressure vessel can be subjected without exceeding the maximum allowable stress of the material or pressure-temperature rating of the equipment. For the purposes of this Code, the term MAWP is as defined in the ASME Boiler and Pressure Vessel Code, Sections I and VIII.

may: may is used to denote permission, neither a requirement nor a recommendation.

mechanical joint: a joint for the purpose of mechanical strength or leak resistance, or both, where the mechanical strength is developed by threaded, grooved, rolled, flared, or flanged pipe ends, or by bolts, pins, and compounds, gaskets, rolled ends, caulking, or machined

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:04 2005

and mated surfaces. These joints have particular application where ease of disassembly is desired.

miter: two or more straight sections of pipe matched and joined on a line bisecting the angle of junction so as to produce a change in direction.

nominal thickness: the thickness given in the product material specification or standard to which manufacturing tolerances are applied.

normalizing: see *heat treatments.*

oxygen cutting: a group of cutting processes wherein the severing of metals is effected by means of the chemical reaction of oxygen with the base metal at elevated temperatures. In the case of oxidation-resistant metals, the reaction is facilitated by use of a flux.

oxygen gouging: an application of oxygen cutting wherein a chamfer or groove is formed.

peening: the mechanical working of metals by means of hammer blows.

pipe and tube: the fundamental difference between pipe and tube is the dimensional standard to which each is manufactured.

A pipe is a tube with a round cross section conforming to the dimensional requirements for nominal pipe size as tabulated in ANSI B36.10, Tables 2 and 4, and ANSI B36.19, Table 1. For special pipe having a diameter not listed in these Tables, and also for round tube, the nominal diameter corresponds with the outside diameter.

A tube is a hollow product of round or any other cross section having a continuous periphery. Round tube size may be specified with respect to any two, but not all three, of the following: outside diameter, inside diameter, wall thickness; types K, L, and M copper tube may also be specified by nominal size and type only. Dimensions and permissible variations (tolerances) are specified in the appropriate ASTM or ASME standard specifications.

Types of pipe, according to the method of manufacture, are defined as follows:

(A) electric resistance welded pipe: pipe produced in individual lengths or in continuous lengths from coiled skelp and subsequently cut into individual lengths, having a longitudinal butt joint wherein coalescence is produced by the heat obtained from resistance of the pipe to the flow of electric current in a circuit of which the pipe is a part, and by the application of pressure.

(B) furnace butt welded pipe

(B.1) furnace butt welded pipe, bell welded: pipe produced in individual lengths from cut length skelp, having its longitudinal butt joint forge welded by the mechanical pressure developed in drawing the furnace heated skelp through a cone shaped die (commonly known as a "welding bell") which serves as a combined forming and welding die.

(B.2) furnace butt welded pipe, continuous welded: pipe produced in continuous lengths from coiled skelp and subsequently cut into individual lengths, having its longitudinal butt joint forge welded by the mechanical pressure developed in rolling the hot formed skelp through a set of round pass welding rolls.

(C) electric fusion welded pipe: pipe having a longitudinal butt joint wherein coalescence is produced in the performed tube by manual or automatic electric arc welding. The weld may be single (welded from one side), or double (welded from inside and outside) and may be made with or without the use of filler metal. Spiral welded pipe is also made by the electric fusion welded process with either a butt joint, a lap joint, or a lock seam joint.

(D) electric flash welded pipe: pipe having a longitudinal butt joint wherein coalescence is produced, simultaneously over the entire area of abutting surfaces, by the heat obtained from resistance to the flow of electric current between the two surfaces, and by the application of pressure after heating is substantially completed. Flashing and upsetting are accompanied by expulsion of metal from the joint.

(E) double submerged arc welded pipe: pipe having a longitudinal butt joint produced by the submerged arc process, with at least two passes, one of which is on the inside of the pipe.

(F) seamless pipe: pipe produced by one or more of the following processes:

(F.1) rolled pipe: pipe produced from a forged billet which is pierced by a conical mandrel between two diametrically opposed rolls. The pierced shell is subsequently rolled and expanded over mandrels of increasingly larger diameter. Where closer dimensional tolerances are desired, the rolled pipe is cold or hot drawn through dies, and machined.

One variation of this process produces the hollow shell by extrusion of the forged billet over a mandrel in a vertical, hydraulic piercing press.

(F.2) forged and bored pipe: pipe produced by boring or trepanning of a forged billet.

(F.3) extruded pipe: pipe produced from hollow or solid round forgings, usually in a hydraulic extrusion press. In this process the forging is contained in a cylindrical die. Initially a punch at the end of the

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:04 2005

extrusion plunger pierces the forging. The extrusion plunger then forces the contained billet between the cylindrical die and the punch to form the pipe, the latter acting as a mandrel.

(F.4) centrifugally cast pipe: pipe formed from the solidification of molten metal in a rotating mold. Both metal and sand molds are used. After casting, the pipe is machined, to sound metal, on the internal and external diameters to the surface roughness and dimensional requirements of the applicable material specification.

One variation of this process utilizes autofrettage (hydraulic expansion) and heat treatment, above the recrystallization temperature of the material, to produce a wrought structure.

(F.5) statistically cast pipe: pipe formed by the solidification of molten metal in a sand mold.

pipe supporting elements: pipe supporting elements consist of hangers, supports, and structural attachments.

hangers and supports: hangers and supports include elements which transfer the load from the pipe or structural attachment to the supporting structure or equipment. They include hanging type fixtures, such as hanger rods, spring hangers, sway braces, counterweights, turnbuckles, struts, chains, guides, and anchors, and bearing type fixtures, such as saddles, bases, rollers, brackets, and sliding supports.

structural attachments: structural attachments include elements which are welded, bolted, or clamped to the pipe, such as clips, lugs, rings, clamps, clevises, straps, and skirts.

porosity: cavity-type discontinuities formed by gas entrapment during metal solidification.

postweld heat treatment: see *heat treatments.*

preheating: see *heat treatments.*

pressure: an application of force per unit area; fluid pressure (an application of internal or external fluid force per unit area on the pressure boundary of piping components).

Procedure Qualification Record (PQR): a record of the welding data used to weld a test coupon. The PQR is a record of variables recorded during the welding of the test coupons. It also contains the test results of the tested specimens. Recorded variables normally fall within a small range of the actual variables that will be used in production welding.

readily accessible: for visual examination, readily accessible inside surfaces are defined as those inside surfaces which can be examined without the aid of optical devices. (This definition does not prohibit the use of optical devices for a visual examination; however, the selection of the device should be a matter of mutual agreement between the owner and the fabricator or erector.)

Reid vapor pressure: the vapor pressure of a flammable or combustible liquid as determined by ASTM Standard Test Method D 323 Vapor Pressure of Petroleum Products (Reid Method).

reinforcement of weld: weld metal on the face of a groove weld in excess of the metal necessary for the specified weld size.

restraint: any device which prevents, resists, or limits movement of a piping system.

root opening: the separation between the members to be joined, at the root of the joint.

root penetration: the depth a groove weld extends into the root opening of a joint measured on the center line of the root cross section.

seal weld: a weld used on a pipe joint primarily to obtain fluid tightness as opposed to mechanical strength.

semiautomatic arc welding: arc welding with equipment which controls only the filler metal feed. The advance of the welding is manually controlled.

shall: "shall" or "shall not" is used to indicate that a provision or prohibition is mandatory.

shielded metal arc welding: an arc welding process wherein coalescence is produced by heating with an electric arc between a covered metal electrode and the work. Shielding is obtained from decomposition of the electrode covering. Pressure is not used and filler metal is obtained from the electrode.

should: "should" or "it is recommended" is used to indicate that a provision is not mandatory but recommended as good practice.

size of weld

groove weld: the joint penetration (depth of chamfering plus the root penetration when specified).

fillet weld: for equal leg fillet welds, the leg lengths of the largest isosceles right triangle which can be inscribed within the fillet weld cross section. For unequal leg fillet welds, the leg lengths of the largest right triangle which can be inscribed within the fillet weld cross section.

slag inclusion: nonmetallic solid material entrapped in weld metal or between weld metal and base metal.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:05 2005

soldering: a metal joining process wherein coalescence is produced by heating to suitable temperature and by using a nonferrous alloy fusible at temperatures below 800°F (425°C) and having a melting point below that of the base metals being joined. The filler metal is distributed between closely fitted surfaces of the joint by capillary action. In general, solders are lead-tin alloys and may contain antimony, bismuth, silver, and other elements.

steel: an alloy of iron and carbon with no more than 2% carbon by weight. Other alloying elements may include manganese, sulfur, phosphorus, silicon, aluminum, chromium, copper, nickel, molybdenum, vanadium, and others depending upon the type of steel. For acceptable material specifications for steel refer to Chapter III, Materials.

stress-relieving: see *heat treatments.*

submerged arc welding: an arc welding process wherein coalescence is produced by heating with an electric arc or arcs between a bare metal electrode or electrodes and the work. The welding is shielded by a blanket of granular, fusible material on the work. Pressure is not used and filler metal is obtained from the electrode and sometimes from a supplementary welding rod.

supplementary steel: steel members which are installed between existing members for the purpose of installing supports for piping or piping equipment.

swivel joint: a component which permits single-plane rotational movement in a piping system.

tack weld: a weld made to hold parts of a weldment in proper alignment until the final welds are made.

throat of a fillet weld

theoretical: the distance from the beginning of the root of the joint perpendicular to the hypotenuse of the largest right triangle that can be inscribed within the fillet weld cross section.

actual: the shortest distance from the root of a fillet weld to its face.

toe of weld: the junction between the face of the weld and the base metal.

tube: refer to *pipe and tube.*

tungsten electrode: a nonfiller metal electrode used in arc welding, consisting of a tungsten wire.

undercut: a groove melted into the base metal adjacent to the toe of a weld and not filled with weld metal.

visual examination: the observation of whatever portions of components, joints, and other piping elements that are exposed to such observation either before, during, or after manufacture, fabrication, assembly, erection, inspection, or testing. This examination may include verification of the applicable requirements for materials, components, dimensions, joint preparation, alignment, welding or joining, supports, assembly, and erection.

weld: a localized coalescence of metal which is produced by heating to suitable temperatures, with or without the application of pressure, and with or without the use of filler metal. The filler metal shall have a melting point approximately the same as the base metal.

welder: one who is capable of performing a manual or semiautomatic welding operation.

Welder/Welding Operator Performance Qualification (WPQ): demonstration of a welder's ability to produce welds in a manner described in a welding procedure specification that meets prescribed standards.

welding operator: one who operates machine or automatic welding equipment.

Welding Procedure Specification (WPS): a written qualified welding procedure prepared to provide direction for making production welds to Code requirements. The WPS or other documents may be used to provide direction to the welder or welding operator to assure compliance with the Code requirements.

weldment: an assembly whose component parts are joined by welding.

CHAPTER II
DESIGN

PART 1
CONDITIONS AND CRITERIA

101 DESIGN CONDITIONS

101.1 General

These design conditions define the pressures, temperatures and various forces applicable to the design of power piping systems. Power piping systems shall be designed for the most severe condition of coincident pressure, temperature and loading, except as herein stated. The most severe condition shall be that which results in the greatest required pipe wall thickness and the highest flange rating.

101.2 Pressure

All pressures referred to in this Code are expressed in pounds per square inch and kilopascals above atmospheric pressure, i.e., psig [kPa (gage)], unless otherwise stated.

101.2.2 Internal Design Pressure. The internal design pressure shall be not less than the maximum sustained operating pressure (MSOP) within the piping system including the effects of static head.

101.2.4 External Design Pressure. Piping subject to external pressure shall be designed for the maximum differential pressure anticipated during operating, shutdown, or test conditions.

101.3 Temperature

101.3.1 All temperatures referred to in this Code, unless otherwise stated, are the average metal temperatures of the respective materials expressed in degrees Fahrenheit, i.e., °F (Celsius, i.e., °C).

101.3.2 Design Temperature

(A) The piping shall be designed for a metal temperature representing the maximum sustained condition expected. The design temperature shall be assumed to be the same as the fluid temperature unless calculations or tests support the use of other data, in which case the design temperature shall not be less than the average of the fluid temperature and the outside wall temperature.

(B) Where a fluid passes through heat exchangers in series, the design temperature of the piping in each section of the system shall conform to the most severe temperature condition expected to be produced by the heat exchangers in that section of the system.

(C) For steam, feedwater, and hot water piping leading from fired equipment (such as boiler, reheater, superheater, economizer, etc.), the design temperature shall be based on the expected continuous operating condition plus the equipment manufacturers guaranteed maximum temperature tolerance. For operation at temperatures in excess of this condition, the limitations described in para. 102.2.4 shall apply.

(D) Accelerated creep damage, leading to excessive creep strains and potential pipe rupture, caused by extended operation above the design temperature shall be considered in selecting the design temperature for piping to be operated above 800°F.

101.4 Ambient Influences

101.4.1 Cooling Effects on Pressure. Where the cooling of a fluid may reduce the pressure in the piping to below atmospheric, the piping shall be designed to withstand the external pressure or provision shall be made to break the vaccum.

101.4.2 Fluid Expansion Effects. Where the expansion of a fluid may increase the pressure, the piping system shall be designed to withstand the increased pressure or provision shall be made to relieve the excess pressure.

101.5 Dynamic Effects

101.5.1 Impact. Impact forces caused by all external and internal conditions shall be considered in the piping design. One form of internal impact force is due to the propagation of pressure waves produced by sudden changes in fluid momentum. This phenomena is often called water or steam "hammer." It may be caused by the rapid opening or closing of a valve in the system.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:07 2005

The designer should be aware that this is only one example of this phenomena and that other causes of impact loading exist.

101.5.2 Wind. Exposed piping shall be designed to withstand wind loadings, using meteorological data to determine wind forces. Where state or municipal ordinances covering the design of building structures are in effect and specify wind loadings, these values shall be considered the minimum design values.

101.5.3 Earthquake. The effect of earthquakes, where applicable, shall be considered in the design of piping, piping supports, and restraints, using data for the site as a guide in assessing the forces involved. However, earthquakes need not be considered as acting concurrently with wind.

101.5.4 Vibration. Piping shall be arranged and supported with consideration of vibration (see paras. 120.1(c) and 121.7.5).

101.6 Weight Effects

The following weight effects combined with loads and forces from other causes shall be taken into account in the design of piping. Piping shall be carried on adjustable hangers or properly leveled rigid hangers or supports, and suitable springs, sway bracing, vibration dampeners, etc., shall be provided where necessary.

101.6.1 Live Load. The live load consists of the weight of the fluid transported. Snow and ice loads shall be considered in localities where such conditions exist.

101.6.2 Dead Load. The dead load consists of the weight of the piping components, insulation, protective lining and coating, and other superimposed permanent loads.

101.6.3 Test or Cleaning Fluid Load. The test or cleaning fluid load consists of the weight of the test or cleaning fluid.

101.7 Thermal Expansion and Contraction Loads

101.7.1 General. The design of piping systems shall take account of the forces and moments resulting from thermal expansion and contraction, and from the effects of expansion joints.

Thermal expansion and contraction shall be provided for preferably by pipe bends, elbows, offsets or changes in direction of the pipeline.

Hangers and supports shall permit expansion and contraction of the piping between anchors.

101.7.2 Expansion, Swivel, or Ball Joints, and Flexible Metal Hose Assemblies. Joints of the corrugated bellows, slip, sleeve, ball, or swivel types and flexible metal hose assemblies may be used if their materials conform to this Code, their structural and working parts are of ample proportions, and their design prevents the complete disengagement of working parts while in service. However, flexible metal hose assemblies, and expansion joints of the corrugated bellows, slip, or sleeve type shall not be used in any piping system connecting the boiler and the first stop valve in that system.

102 DESIGN CRITERIA

102.1 General

These criteria cover pressure-temperature ratings for standard and specially designed components, allowable stresses, stress limits, and various allowances to be used in the design of piping and piping components.

102.2 Pressure-Temperature Ratings for Piping Components

102.2.1 Components Having Specific Ratings. Pressure-temperature ratings for certain piping components have been established and are contained in some of the standards listed in Table 126.1.

Where piping components have established pressure-temperature ratings which do not extend to the upper material temperature limits permitted by this Code, the pressure-temperature ratings between those established and the upper material temperature limit may be determined in accordance with the rules of this Code, but such extensions are subject to restrictions, if any, imposed by the standards.

Standard components may not be used at conditions of pressure and temperature which exceed the limits imposed by this Code.

102.2.2 Components Not Having Specific Ratings. Some of the Standards listed in Table 126.1, such as those for buttwelding fittings, specify that components shall be furnished in nominal thicknesses. Unless limited elsewhere in this Code, such components shall be rated

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:07 2005

for the same allowable pressures as seamless pipe of the same nominal thickness, as determined in paras. 103 and 104 for material having the same allowable stress.

Piping components, such as pipe, for which allowable stresses have been developed in accordance with para. 102.3, but which do not have established pressure ratings, shall be rated by rules for pressure design in para. 104, modified as applicable by other provisions of this Code.

Should it be desired to use methods of manufacture or design of components not covered by this Code or not listed in referenced standards, it is intended that the manufacturer shall comply with the requirements of paras. 103 and 104 and other applicable requirements of this Code for design conditions involved. Where components other than those discussed above, such as pipe or fittings not assigned pressure-temperature ratings in an American National Standard, are used, the manufacturer's recommended pressure-temperature rating shall not be exceeded.

102.2.3 Ratings: Normal Operating Condition. A piping system shall be considered safe for operation if the maximum sustained operating pressure and temperature which may act on any part or component of the system does not exceed the maximum pressure and temperature allowed by this Code for that particular part or component. The design pressure and temperature shall not exceed the pressure-temperature rating for the particular component and material as defined in the applicable specification or standard listed in Table 126.1.

102.2.4 Ratings: Allowance for Variation From Normal Operation. The maximum internal pressure and temperature allowed shall include considerations for occasional loads and transients of pressure and temperature.

It is recognized that variations in pressure and temperature inevitably occur, and therefore the piping system, except as limited by component standards referred to in para. 102.2.1 or by manufacturers of components referred to in para. 102.2.2, shall be considered safe for occasional short operating periods at higher than design pressure or temperature. For such variations, either pressure or temperature, or both, may exceed the design values if the computed circumferential pressure stress does not exceed the maximum allowable stress from Appendix A for the coincident temperature by:

(A) 15% if the event duration occurs for no more than 8 hr at any one time and no more than 800 hr/year; or

(B) 20% if the event duration occurs for no more than 1 hr at any one time and no more than 80 hr/year.

102.2.5 Ratings at Transitions. Where piping systems operating at different design conditions are connected, a division valve shall be provided having a pressure-temperature rating equal to or exceeding the more severe conditions. See para. 122 for design requirements pertaining to specific piping systems.

102.3 Allowable Stress Values and Other Stress Limits for Piping Components

102.3.1 Allowable Stress Values

(A) Allowable stress values to be used for the design of power piping systems are given in the Tables in Appendix A, also referred to in this Code Section as the Allowable Stress Tables. These Tables list allowable stress values for commonly used materials at temperatures appropriate to power piping installations. In every case the temperature is understood to be the metal temperature. Where applicable, weld joint efficiency factors and casting quality factors are included in the tabulated values. Thus, the tabulated values are values of *S*, *SE*, or *SF*, as applicable.

(B) Allowable stress values in shear shall not exceed 80% of the values determined in accordance with the rules of para. 102.3.1(A). Allowable stress values in bearing shall not exceed 160% of the determined values.

(C) The basis for establishing the allowable stress values in this Code Section are the same as those in the ASME Boiler and Pressure Vessel Code, Section II, Part D, Appendix 1; except that allowable stresses for cast iron and ductile iron are in accordance with Section VIII, Division 1, Appendix P for Tables UCI-23 and UCD-23, respectively.

102.3.2 Limits of Calculated Stresses Due to Sustained Loads and Thermal Expansion

(A) Internal Pressure Stress. The calculated stress due to internal pressure shall not exceed the allowable stress values given in the Allowable Stress Tables in Appendix A. This criterion is satisfied when the wall thickness of the piping component, including any reinforcement, meets the requirements of para. 104.1 through 104.7, excluding para. 104.1.3 but including the consideration of allowances permitted by paras. 102.2.4, 102.3.3(B), and 102.4.

(B) External Pressure Stress. Piping subject to external pressure shall be considered safe when the wall thickness and means of stiffening meet the requirements of para. 104.1.3.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:08 2005

TABLE 102.3.2(C)
STRESS RANGE REDUCTION FACTORS

Number of Equivalent Full Temperature Cycles N	f
7,000 and less	1.0
7,000–14,000	0.9
14,000–22,000	0.8
22,000–45,000	0.7
45,000–100,000	0.6
100,000 and over	0.5

(C) Allowable Stress Range for Expansion Stresses. Except as permitted in para. 102.3.2(D), the thermal expansion stress range S_E (see paras. 104.8.3 and 119.6.4) shall not exceed the allowable stress range S_A given by the following formula:

$$S_A = f(1.25S_c + 0.25S_h) \quad (1)$$

where

S_c = basic material allowable stress at minimum (cold) temperature from the Allowable Stress Tables

S_h = basic material allowable stress at maximum (hot) temperature from the Allowable Stress Tables

f = stress range reduction factor for cyclic conditions for total number N of full temperature cycles over total number of years during which system is expected to be in operation, from Table 102.3.2(C)

In determining the basic material allowable stresses, S_c and S_h, joint efficiencies need not be applied. The values of allowable stress in the Allowable Stress Tables for welded pipe may be divided by the weld joint factors listed in para. 102.4.3.

Stress reduction factors apply essentially to noncorrosive service and to corrosion resistant materials where employed to minimize the reduction in cyclic life caused by corrosive action.

If the range of temperature change varies, equivalent full temperature cycles may be computed as follows:

$$N = N_E + r_1^5 N_1 + r_2^5 N_2 + \ldots + r_n^5 N_n \quad (2)$$

where

N_E = number of cycles at full temperature change ΔT_E for which expansion stress S_E has been calculated

$N_1, N_2, \ldots, N_n$ = number of cycles at lesser temperature changes $\Delta T_1, \Delta T_2, \ldots, \Delta T_n$

$r_1, r_2, \ldots, r_n$ = ratio of lesser temperature cycles to that for any which the expansion stress S_E has been calculated = $\Delta T_1/\Delta T_E, \Delta T_2/\Delta T_E, \ldots, \Delta T_n/\Delta T_E$

(D) Longitudinal Stresses. The sum of the longitudinal stresses S_L due to pressure, weight, and other sustained loads shall not exceed the allowable stress in the hot condition S_h. Where the sum of these stresses is less than S_h, the difference may be used as an additional thermal expansion allowance, which is the second term on the right side of Eq. (13) of para. 104.8.3.

The longitudinal pressure stress S_{lp} shall be determined by either of the following equations:

$$S_{lp} = \frac{PD_o}{4t_n}$$

or

$$S_{lp} = \frac{Pd_n^2}{D_n^2 - d_n^2}$$

102.3.3 Limits of Calculated Stresses due to Occasional Loads

(A) During Operation. The sum of the longitudinal stresses produced by internal pressure, live and dead loads and those produced by occasional loads, such as the temporary supporting of extra weight, may exceed the allowable stress values given in the Allowable Stress Tables by the amounts and durations of time given in para. 104.8.2.

(B) During Test. During pressure tests performed in accordance with para. 137, the circumferential (hoop) stress shall not exceed 90% of the yield strength (0.2% offset) at test temperature. In addition, the sum of longitudinal stresses due to test pressure and live and dead loads at the time of test, excluding occasional loads, shall not exceed 90% of the yield strength at test temperature.

102.4 Allowances

102.4.1 Corrosion or Erosion. When corrosion or erosion is expected, an increase in wall thickness of the piping shall be provided over that required by other

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:09 2005

design requirements. This allowance in the judgment of the designer shall be consistent with the expected life of the piping.

102.4.2 Threading and Grooving. The calculated minimum thickness of piping (or tubing) which is to be threaded shall be increased by an allowance equal to thread depth; dimension h of ASME B1.20.1 or equivalent shall apply. For machined surfaces or grooves, where the tolerance is not specified, the tolerance shall be assumed to be $\frac{1}{64}$ in. (0.40 mm) in addition to the specified depth of cut. The requirements of para. 104.1.2(C) shall also apply.

102.4.3 Weld Joint Efficiency Factors. The use of joint efficiency factors for welded pipe is required by this Code. The factors in Table 102.4.3 are based on full penetration welds. These factors are included in the allowable stress values given in Appendix A. The factors in Table 102.4.3 apply to both straight seam and spiral seam welded pipe.

102.4.4 Mechanical Strength. Where necessary for mechanical strength to prevent damage, collapse, excessive sag, or buckling of pipe due to superimposed loads from supports or other causes, the wall thickness of the pipe should be increased; or, if this is impractical or would cause excessive local stresses, the superimposed loads or other causes shall be reduced or eliminated by other design methods. The requirements of para. 104.1.2(C) shall also apply.

102.4.5 Bending. The minimum wall thickness at any point in a completed bend shall not be less than required by Formulas (3) or (3A) of para. 104.1.2(A).

(A) Table 102.4.5 is a guide to the designer who must specify wall thickness for ordering pipe. In general it has been the experience that when good shop practices are employed, the minimum thicknesses of straight pipe shown in Table 102.4.5 should be sufficient for bending, and still meet the minimum thickness requirements of para. 104.1.2(A).

(B) The bend thinning allowance in Table 102.4.5 may be provided in all parts of the cross section of the pipe circumference without any detrimental effects being produced.

102.4.6 Casting Quality Factors

(A) General. The use of a casting quality factor is required for all cast components which use the allowable stress values of Appendix A as the design basis. A factor of 0.80 is included in the allowable stress values for all castings given in Appendix A.

This required factor does not apply to component standards listed in Table 126.1, if such standards define allowable pressure-temperature ratings or provide the allowable stresses to be used as the design basis for the component.

(B) For steel materials, a casting quality factor not exceeding 1.0 may be applied when the following requirements are met.

(B.1) All steel castings having a nominal body thickness of $4\frac{1}{2}$ in. (114 mm) or less (other than pipe flanges, flanged valves and fittings, and butt welding end valves, all complying with ASME B16.5 or B16.34) shall be inspected as follows.

(B.1.1) All critical areas, including the junctions of all gates, risers, and abrupt changes in section or direction and area of weld end preparation shall be radiographed in accordance with Article 2 of Section V of the ASME Boiler and Pressure Vessel Code, and the radiographs shall conform to the requirements of ASTM E 446 Reference Radiographs for Steel Castings up to 2 in. (50 mm) in Thickness or E 186 Reference Radiographs for Heavy Walled [2 to $4\frac{1}{2}$ in. (50 to 114 mm)] Steel Castings, depending upon the section thickness. The maximum acceptable severity level for a 1.0 quality factor shall be as listed in Table 102.4.6(B.1.1).

(B.1.2) All surfaces of each casting, including machined gasket seating surfaces, shall be examined by the magnetic particle or dye penetrant method after heat treatment. The examination techniques shall be in accordance with Article 6 or 7, as applicable, and Article 9 of Section V of the ASME Boiler and Pressure Vessel Code. Magnetic particle or dye penetrant indications exceeding degree 1 of Type I, degree 2 of Type II, and degree 3 of Type III, and exceeding degree 1 of Types IV and V of ASTM E 125, Standard Reference Photographs for Magnetic Particle Indications on Ferrous Castings, are not acceptable and shall be removed.

(B.1.3) Where more than one casting of a particular design is produced, each of the first five castings shall be inspected as above. Where more than five castings are being produced, the examination shall be performed on the first five plus one additional casting to represent each five additional castings. If this additional casting proves to be unacceptable, each of the remaining castings in the group shall be inspected.

(B.1.4) Any discontinuities in excess of the maximum permitted in (B.1.1) and (B.1.2) above shall be removed, and the casting may be repaired by welding after the base metal has been inspected to assure complete removal of discontinuities. [Refer to para. 127.4.11(A).] The completed repair shall be subject to

TABLE 102.4.3
LONGITUDINAL WELD JOINT EFFICIENCY FACTORS

No.	Type of Joint	Type of Seam	Examination	Factor *E*
1	Furnace butt weld, continuous weld	Straight	As required by listed specification	0.60 [Note (1)]
2	Electric resistance weld	Straight or spiral	As required by listed specification	0.85 [Note (1)]
3	Electric fusion weld			
	(a) Single butt weld (without filler metal)	Straight or spiral	As required by listed specification	0.85
			Additionally 100% radiographed	1.00 [Note (2)]
	(b) Single butt weld (with filler metal)	Straight or spiral	As required by listed specification	0.80
			Additionally 100% radiographed	1.00 [Note (2)]
	(c) Double butt weld (without filler metal)	Straight or spiral	As required by listed specification	0.90
			Additionally 100% radiographed	1.00 [Note (2)]
	(d) Double butt weld (with filler metal)	Straight or spiral	As required by listed specification	0.90
			Additionally 100% radiographed	1.00 [Note (2)]
4	API 5L Submerged arc weld (SAW) Gas metal arc weld (GMAW) Combined GMAW, SAW	Straight with one or two seams Spiral	As required by specification	0.90
			Additionally 100% radiographed	1.00 [Note (2)]

NOTES:
(1) It is not permitted to increase the longitudinal weld joint efficiency factor by additional examination for joint 1 or 2.
(2) Radiography shall be in accordance with the requirements of para. 136.4.5 or the material specification as applicable.

reinspection by the same method as was used in the original inspection and shall be reinspected after any required postweld heat treatment.

(B.2) All steel castings having a nominal body thickness greater than 4½ in. (114 mm) (other than pipe flanges, flanged valves and fittings, and butt welding end valves, all complying with ASME B16.5 or B16.34) shall be inspected as follows.

(B.2.1) All surfaces of each casting including machined gasket seating surfaces, shall be examined by the magnetic particle or dye penetrant method after heat treatment. The examination techniques shall be in accordance with Article 6 or 7, as applicable, and with Article 9 of Section V of the ASME Boiler and Pressure Vessel Code. Magnetic particle or dye penetrant indications exceeding degree 1 of Type I, degree 2 of Type II, and degree 3 of Type III and exceeding degree 1 of Types IV and V of ASTM E 125, Standard Reference

TABLE 102.4.5

Radius of Bends	Min. Thickness Recommended Prior to Bending
6 pipe diameters or greater	$1.06t_m$
5 pipe diameters	$1.08t_m$
4 pipe diameters	$1.14t_m$
3 pipe diameters	$1.25t_m$

GENERAL NOTES:
(a) Interpolation is permissible for bending to intermediate radii.
(b) t_m is determined by Formula (3) or (3A) of para. 104.1.2(A).
(c) Pipe diameter is the nominal diameter as tabulated in ASME B36.10M, Tables 2 and 4, and ASME B36.19M, Table 1. For piping with a diameter not listed in these Tables, and also for tubing, the nominal diameter corresponds with the outside diameter.

Photographs for Magnetic Particle Indications on Ferrous Castings, shall be removed.

(B.2.2) All parts of castings shall be subjected to complete radiographic inspection in accordance with Article 2 of Section V of the ASME Boiler and Pressure Vessel Code, and the radiographs shall conform to the requirements of ASTM E 280, Reference Radiographs for Heavy Walled [4½ to 12 in. (114 to 305 mm)] Steel Castings.

The maximum acceptable severity level for a 1.0 quality factor shall be as listed in Table 102.4.6 (B.2.2).

(B.2.3) Any discontinuities in excess of the maximum permitted in (B.2.1) and (B.2.2) above shall be removed and may be repaired by welding after the base metal has been magnetic particle or dye penetrant inspected to assure complete removal of discontinuities. [Refer to para. 127.4.11(A).]

(B.2.4) All weld repairs of depth exceeding 1 in. (25 mm) or 20% of the section thickness, whichever is the lesser, shall be inspected by radiography in accordance with (B.2.2) above and by magnetic particle or dye penetrant inspection of the finished weld surface. All weld repairs of depth less than 20% of the section thickness, or 1 in. (25 mm), whichever is the lesser, and all weld repairs of section which cannot be effectively radiographed shall be examined by magnetic particle or dye penetrant inspection of the first layer, of each ¼ in. (6 mm) thickness of deposited weld metal, and of the finished weld surface. Magnetic particle or dye penetrant testing of the finished weld surface shall be done after postweld heat treatment.

(C) For cast iron and nonferrous materials, no increase of the casting quality factor is allowed except when special methods of examination, prescribed by the material specification, are followed. If such increase is specifically permitted by the material specification, a factor not exceeding 1.0 may be applied.

PART 2
PRESSURE DESIGN OF PIPING COMPONENTS

103 CRITERIA FOR PRESSURE DESIGN OF PIPING COMPONENTS

The design of piping components shall consider the effects of pressure and temperature, in accordance with paras. 104.1 through 104.7, including the consideration of allowances permitted by paras. 102.2.4 and 102.4. In addition, the mechanical strength of the piping system shall be determined adequate in accordance with para. 104.8 under other applicable loadings, including but not limited to those loadings defined in para. 101.

104 PRESSURE DESIGN OF COMPONENTS

104.1 Straight Pipe

104.1.2 Straight Pipe Under Internal Pressure

(A) Minimum Wall Thickness. The minimum thickness of pipe wall required for design pressures and for temperatures not exceeding those for the various materials listed in the Allowable Stress Tables, including allowances for mechanical strength, shall not be less than that determined by Formula (3) or (3A), as follows:

$$t_m = \frac{PD_o}{2(SE + Py)} + A \qquad (3)^1$$

$$t_m = \frac{Pd + 2SEA + 2yPA}{2(SE + Py - P)} \qquad (3A)^1$$

Design pressure shall not exceed

$$P = \frac{2SE(t_m - A)}{D_o - 2y(t_m - A)} \qquad (4)^1$$

$$P = \frac{2SE(t_m - A)}{d - 2y(t_m - A) + 2t_m} \qquad (4A)^1$$

[1] *SF* shall be used in place of *SE* where casting quality factors are intended. See definition of *SE*. Units of *P* and *SE* must be identical. Appendix A values must be converted to kPa when the design pressure is in kPa.

A, B, and Types 1,2, and 3 of C	2
D, E, and F	None acceptable

where the nomenclature used above are:

(A.1) t_m = minimum required wall thickness, in. (mm)

(A.1.1) If pipe is ordered by its nominal wall thickness, the manufacturing tolerance on wall thickness must be taken into account. After the minimum pipe wall thickness t_m is determined by Formula (3) or (3A), this minimum thickness shall be increased by an amount sufficient to provide the manufacturing tolerance allowed in the applicable pipe specification or required by the process. The next heavier commercial wall thickness shall then be selected from thickness schedules such as contained in ASME B36.10M or from manufacturers' schedules for other than standard thickness.

(A.1.2) To compensate for thinning in bends, refer to para. 102.4.5.

(A.1.3) For cast piping components, refer to para. 102.4.6.

(A.1.4) Where ends are subject to forming or machining for jointing, the wall thickness of the pipe, tube, or component after such forming or machining shall not be less than t_m minus the amount provided for removal by para. 104.1.2 (A.6.1).

(A.2) P = internal design pressure, psig [kPa (gage)]

NOTE: When computing the design pressure for a pipe of a definite minimum wall thickness by Formula (4) or (4A), the value of P obtained by these Formulas may be rounded out to the next higher unit of 10. For cast iron pipe, see para. 104.1.2(B).

(A.3) D_o = outside diameter of pipe, in. (mm). For design calculations, the outside diameter of pipe as given in tables of standards and specifications shall be used in obtaining the value of t_m. When calculating the allowable working pressure of pipe on hand or in stock, the actual measured outside diameter and actual measured minimum wall thickness at the thinner end of the pipe may be used to calculate this pressure.

(A.4) d = inside diameter of pipe, in. (mm). For design calculations, the inside diameter of pipe is the maximum possible value allowable under the purchase specification. When calculating the allowable working pressure of pipe on hand or in stock, the actual measured inside diameter and actual measured minimum wall thickness at the thinner end of the pipe may be used to calculate this pressure.

TABLE 104.1.2(A)
VALUES OF y

Temperature, °F	900 and Below	950	1000	1050	1100	1150	1200	1250 and Above
Temperature, °C	482 and Below	510	538	566	593	621	649	677 and Above
Ferritic steels	0.4	0.5	0.7	0.7	0.7	0.7	0.7	0.7
Austenitic steels	0.4	0.4	0.4	0.4	0.5	0.7	0.7	0.7
Nickel Alloys UNS Nos. N08800, N08810, N08825	0.4	0.4	0.4	0.4	04	0.4	0.5	0.7

GENERAL NOTES:

(a) The value of y may be interpolated between the 50°F (27.8°C) values shown in the Table. For cast iron and nonferrous materials, y equals 0.4.

(b) For pipe with a D_o/t_m ratio less than 6, the value of y for ferritic and austenitic steels designed for temperatures of 900°F (480°C) and below shall be taken as:

$$y = \frac{d}{d + D_o} \quad (5)$$

(A.5) SE or *SF* = maximum allowable stress in material due to internal pressure and joint efficiency (or casting quality factor) at the design temperature, psi (kPa). The value of *SE* or *SF* shall not exceed that given in Appendix A, for the respective material and design temperature. These values include the weld joint efficiency *E*, or the casting factor *F*.

(A.6) A = additional thickness, in. (mm):

(A.6.1) to compensate for material removed in threading, grooving, etc., required to make a mechanical joint, refer to para. 102.4.2;

(A.6.2) to provide for mechanical strength of the pipe, refer to para. 102.-4.4 (not intended to provide for extreme conditions of misapplied external loads or for mechanical abuse);

(A.6.3) to provide for corrosion and/or erosion, refer to para. 102.4.1;

(A.6.4) for cast iron pipe the following values of *A* shall apply:

Centrifugally cast . . . . . 0.14 in. (3.56 mm)
Statically cast . . . . . 0.18 in. (4.57 mm)

(A.7) y = coefficient having values as given in Table 104.1.2(A)

(B) The thickness of gray and ductile iron pipe and fittings conveying liquids may be determined from ANSI/AWWA C110/A21.10, ANSI/AWWA C115/A21.15, ANSI/AWWA C150/A21.50, ANSI/AWWA C151/A21.51, or Federal Specification WW-P-421, using the class of pipe for the pressure next higher than the desired internal design pressure in psi (kPa). These thickness include allowances for foundry tolerances and water hammer. Where the thickness of ductile iron pipe for liquid service is calculated, the methods of ANSI/AWWA C115/A21.15, or ANSI/AWWA C150/A21.50 may be used.

Where cast gray and ductile iron pipe is used for steam service, the thickness shall be calculated in accordance with Formula (3) or (3A) using the allowable stress value from the Allowable Stress Tables.

(C) While the thickness determined from Formula (3) or (3A) are theoretically ample for both bursting pressure and material removed in threading, the following minimum requirements are mandatory to furnish added mechanical strength.

(C.1) Where steel pipe is threaded and used for steam service at pressure above 250 psi (1750 kPa) or for water service above 100 psi (700 kPa) with water temperature above 220°F (105°C), the pipe shall be seamless having the minimum ultimate tensile strength of 48,000 psi (330 MPa) and a weight at least equal to Schedule 80 of ASME B36.10M. 01

(C.2) Where threaded brass or copper pipe is used for the services described in (C.1) above, it shall comply with pressure and temperature classifications permitted for these materials by other paragraphs of this Code and shall have a wall thickness at least equal to that specified above for steel pipe of corresponding size.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:11 2005

(C.3) Plain end nonferrous pipe or tube shall have minimum wall thicknesses as follows.

For nominal sizes smaller than NPS $^3/_4$, the thickness shall not be less than that specified for Type K of ASTM B 88.

For nominal sizes NPS $^3/_4$ and larger, the wall thickness shall not be less than 0.049 in. (1.25 mm). The wall thickness shall be further increased, as required, in accordance with para. 102.4.

104.1.3 Straight Pipe Under External Pressure. For determining wall thickness and stiffening requirements for straight pipe under external pressure, the procedures outlined in UG-28, UG-29, and UG-30 of Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code shall be followed.

104.2 Curved Segments of Pipe

104.2.1 Pipe Bends. Pipe bends shall be subject to the following limitations.

(A) The minimum wall thickness shall meet the requirements of para. 102.4.5 and the fabrication requirements of para. 129.

(B) For ferrous material, when the radius of a bend is 5 nominal pipe diameters or greater, and the nominal wall thickness of the pipe is schedule 40 or thicker, the difference between maximum and minimum diameters shall not exceed 8% of average measured outside diameter of the pipe before bending.

(C) Greater flattening may be permitted or less flattening may be required by the design, depending upon the service, the material, and the stress level involved.

104.2.2 Elbows. Elbows manufactured in accordance with the standards listed in Table 126.1 are suitable for use at the pressure-temperature ratings specified by such standards, subject to the requirements of para. 106.

104.3 Intersections

104.3.1 Branch Connections

(A) This paragraph gives rules governing the design of branch connections to sustain internal and external pressure in cases where the axes of the branch and the run intersect, and the angle between the axes of the branch and of the run is between 45 deg and 90 deg, inclusive.

Branch connections in which the smaller angle between the axes of the branch and the run is less than 45 deg or branch connections where the axes of the branch and the run do not intersect impose special design and fabrication problems. The rules given herein may be used as a guide, but sufficient additional strength must be provided to assure safe service. Such branch connections shall be designed to meet the requirement of para. 104.7.

(B) Branch connections in piping may be made from materials listed in Appendix A by the use of the following:

(B.1) fittings, such as tees, laterals, and crosses made in accordance with the applicable standards listed in Table 126.1 where the attachment of the branch pipe to the fitting is by butt welding, socket welding, brazing, soldering, threading, or by a flanged connection;

(B.2) weld outlet fittings, such as cast or forged nozzles, couplings and adaptors, or similar items where the attachment of the branch pipe to the fitting is by butt welding, socket welding, threading, or by a flanged connection. Such weld outlet fittings are attached to the run by welding similar to that shown in Fig. 127.4.8(E). Couplings are restricted to a maximum of NPS 3.

(B.3) extruded outlets at right angles to the run pipe, in accordance with (G) below, where the attachment of the branch pipe is by butt welding;

(B.4) piping directly attached to the run pipe by welding in accordance with para. 127.4.8 or by socket welding or threading as stipulated below:

(B.4.1) socket welded right angle branch connections may be made by attaching the branch pipe directly to the run pipe provided:

(B.4.1.1) the nominal size of the branch does not exceed NPS 2 or one-fourth of the nominal size of the run, whichever is smaller;

(B.4.1.2) the depth of the socket measured at its minimum depth in the run pipe is at least equal to that shown in ASME B16.11. If the run pipe wall does not have sufficient thickness to provide the proper depth of socket, an alternate type of construction shall be used.

(B.4.1.3) the clearance between the bottom of the socket and the end of the inserted branch pipe is in accordance with Fig. 127.4.4(C);

(B.4.1.4) the size of the fillet weld is not less than 1.09 times the nominal wall thickness of the branch pipe.

(B.4.2) threaded right angle branch connections may be made by attaching the branch pipe directly to the run provided:

(B.4.2.1) the nominal size of the branch does not exceed NPS 2 or one-fourth of the nominal size of the run whichever is smaller;

(B.4.2.2) the minimum thread engagement is: 6 full threads for NPS $^1/_2$ and NPS $^3/_4$ branches; 7 for NPS 1, NPS $1^1/_4$, and NPS $1^1/_2$ branches; and 8 for NPS 2

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:12 2005

branches. If the run pipe wall does not have sufficient thickness to provide the proper depth for thread engagement, an alternative type of construction shall be used.

(C) Branch Connections Not Requiring Reinforcement. A pipe having a branch connection is weakened by the opening that must be made in it. Unless the wall thickness of the branch and/or run pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide additional material in order to meet the reinforcement requirements of (D) and (E) below. However, there are certain branch connections for which supporting calculations are not required. These are as follows:

(C.1) branch connections made by the use of a fitting (tee, lateral, cross, or branch weld-on fitting), manufactured in accordance with a standard listed in Table 126.1, and used within the limits of pressure-temperature ratings specified in that standard;

(C.2) branch connections made by welding a coupling or half coupling directly to the run pipe in accordance with Fig. 127.4.8(E) provided the nominal diameter of the branch does not exceed NPS 2 or one-fourth the nominal diameter of the run, whichever is less. The minimum wall thickness of the coupling anywhere in the reinforcement zone (if threads are in the zone, wall thickness is measured from the root of the thread to the minimum O.D.) shall not be less than that of the unthreaded branch pipe. In no case shall the thickness of the coupling be less than extra heavy or Class 3000 rating.

Small branch connections NPS 2 or smaller as shown in Fig. 127.4.8(F) may be used provided t_w is not less than the thickness of schedule 160 pipe of the branch size.

(C.3) integrally reinforced fittings welded directly to the run pipe when the reinforcements provided by the fitting and the deposited weld metal meets the requirements of (D) below.

(C.4) integrally reinforced extruded outlets in the run pipe. The reinforcement requirements shall be in accordance with (G) below.

(D) Branch Connections Subject to Internal Pressure Requiring Reinforcement

(D.1) Reinforcement is required when it is not provided inherently in the components of the branch connection. This paragraph gives rules covering the design of branch connections to sustain internal pressure in cases where the angle between the axes of the branch and of the run is between 45 deg and 90 deg Subparagraph (E) below gives rules governing the design of connections to sustain external pressure.

(D.2) Figure 104.3.1(D) illustrates the notations used in the pressure-temperature design conditions of branch connections but does not illustrate the allowances for mill tolerance or any other wall thickness allowance. The designer shall make proper allowances for the effects of corrosion or erosion, threading and grooving, and mechanical strength as specified in paras. 102.4.1, 102.4.2, and 102.4.4 in order that the required minimum reinforcement is assured over the design life of the piping system. These notations are as follows:

α = angle between axes of branch and run, deg

b = subscript referring to branch

D_o = outside diameter of pipe, in. (mm)

d_1 = inside center line longitudinal dimension of the finished branch opening in the run of the pipe, in. (mm)
= $[D_{ob} - 2(T_b - A)]/\sin\alpha$

d_2 = "half width" of reinforcing zone, in. (mm)
= the greater of d_1 or $(T_b - A) + (T_h - A) + d_1/2$ but in no case more than D_{oh}, in. (mm)

h = subscript referring to run or header

L_4 = altitude of reinforcement zone outside of run, in. (mm)
= $2.5(T_b - A) + t_r$ or $2.5(T_h - A)$, whichever is smaller

t_r = thickness of attached reinforcing pad, in Example B, in. (mm); or height of the largest 60 deg right triangle supported by the run and branch outside diameter projected surfaces and lying completely within the area of integral reinforcement, in Example C, in. (mm)

T_b, T_h = actual (by measurement), or minimum wall thickness of the branch or header pipe, in. (mm), permissible under purchase specification

t_{mb}, t_{mh} = required minimum wall thickness, in. (mm), of the branch or header pipe as determined by use of Formula (3) or (3A) in para. 104.1.2(A)

(D.2.1) If the run pipe contains a longitudinal seam which is not intersected by the branch, the stress value of seamless pipe of comparable grade may be used to determine the value of t_{mh} for the purpose of reinforcement calculations only. If the branch intersects a longitudinal weld in the run, or if the branch contains a weld, the weld joint efficiency for either or both shall enter the calculations. If the branch and run both contain longitudinal welds, care shall be taken to ensure that the two welds do not intersect each other.

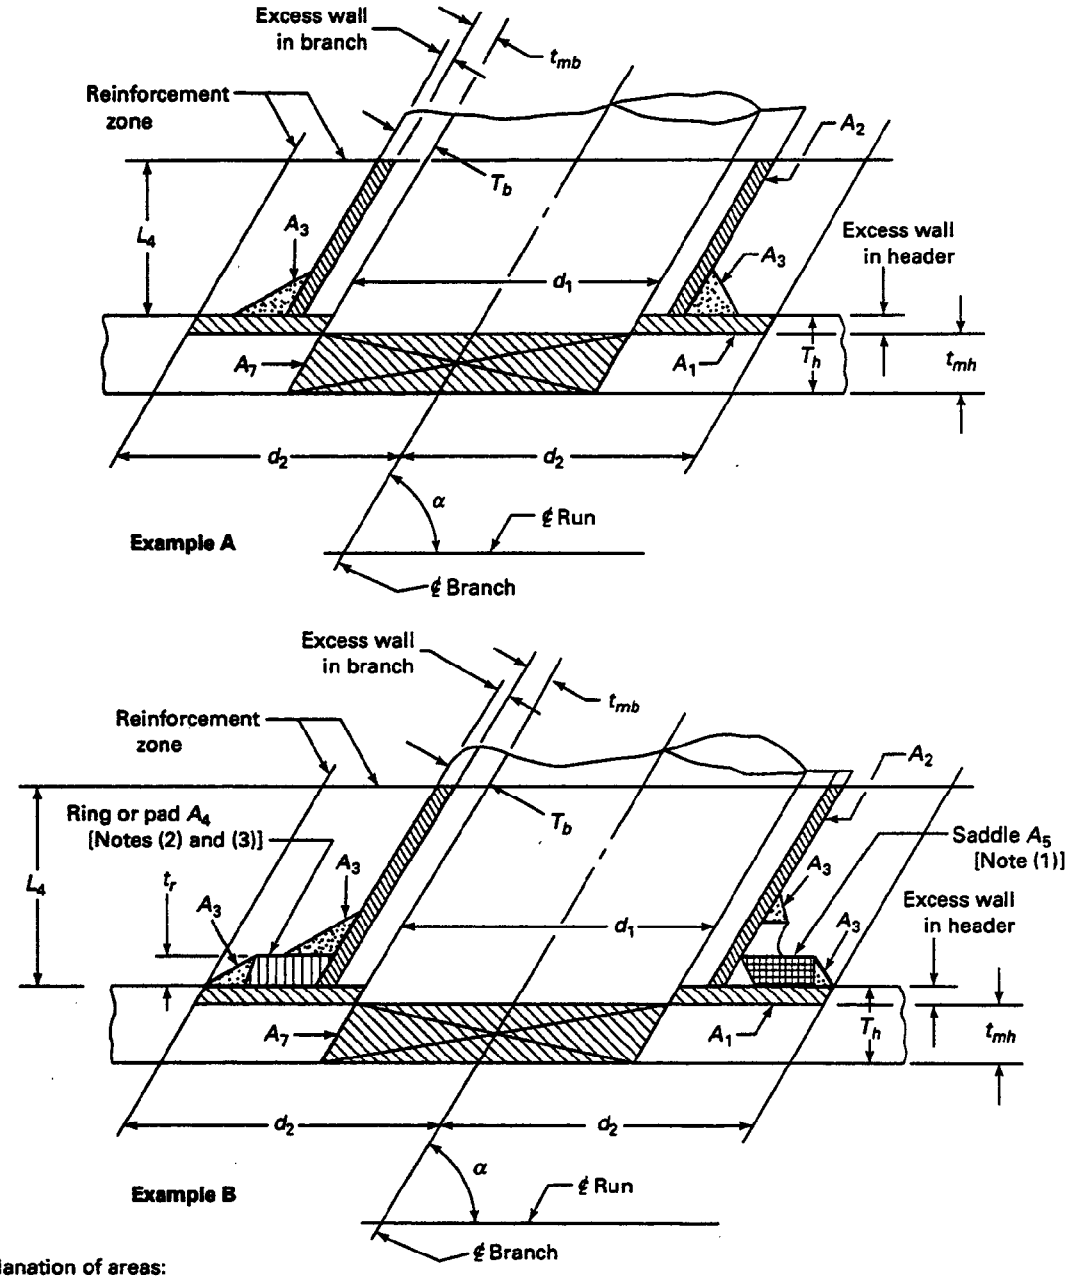
required reinforcement = $(t_{mh})\ (d_1)\ (2 - \sin \alpha) = A_7$

reinforcement areas = A_1, A_2, A_3, A_4, and A_5



Explanation of areas:

Area A_7 — required reinforcement area

Area A_1 — excess wall in header

Area A_2 — excess wall in branch

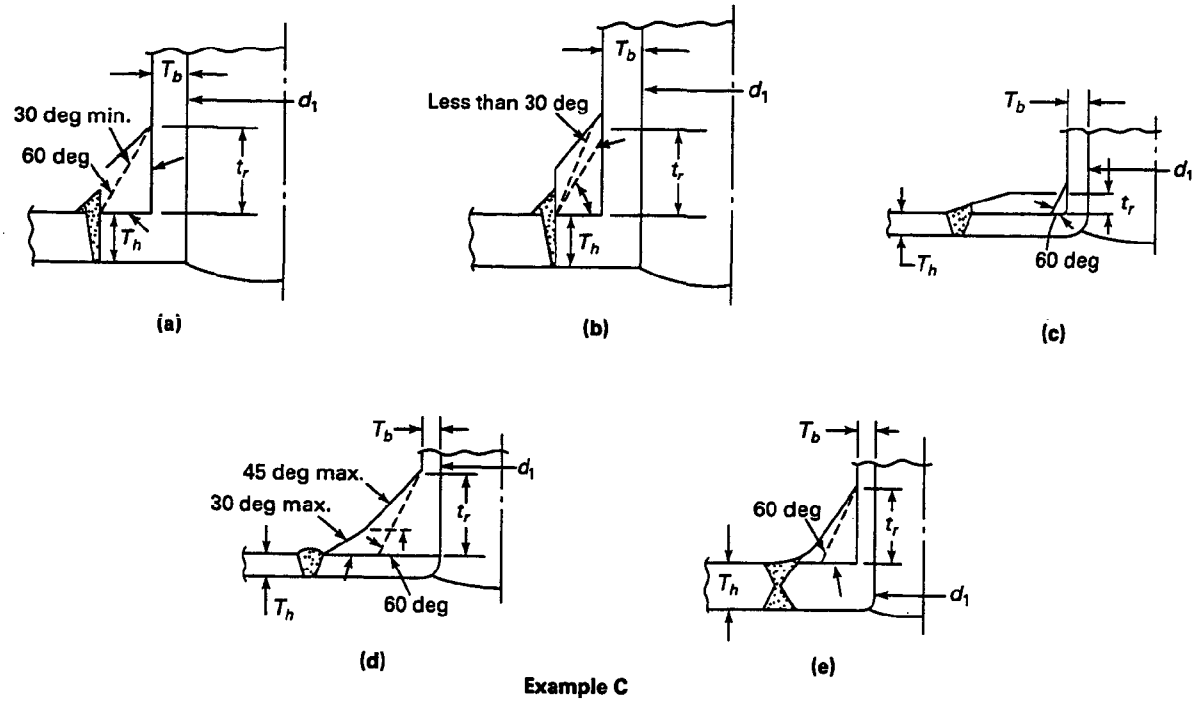
Area A_3 — fillet weld metal

Area A_4 — metal in ring, pad, or integral reinforcement

Area A_5 — metal in saddle along run

FIG. 104.3.1(D) REINFORCEMENT OF BRANCH CONNECTIONS

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:12 2005



Example C

NOTES:

(1) Reinforcing saddles are limited to use on 90 deg branches.

(2) When a ring or pad is added as reinforcement (Example B), the value of reinforcing area may be taken in the same manner in which excess header metal is considered, provided the weld completely fuses the branch pipe, header pipe, and ring or pad. Typical acceptable methods of welding that meet the above requirement are shown in Fig. 127.4.8(D), examples (c) and (d).

(3) Width to height of rings and pads shall be reasonably proportioned, preferably on a ratio as close to 4:1 as the available horizontal space within the limits of the reinforcing zone along the run and the O.D. of the branch will permit, but in no case may the ratio be less than 1:1.

FIG. 104.3.1(D) REINFORCEMENT OF BRANCH CONNECTIONS (CONT'D)

01 *(D.2.2)* The required reinforcement area in square inches (square millimeters) for branch connections shall be the quantity

$$A_7 = (t_{mh} - A)d_1\,(2 - \sin\alpha)$$

For right angle connections the required reinforcement becomes

$$A_7 = t_{mh}d_1$$

The required reinforcement must be within the limits of the reinforcement zone as defined in (D.2.4) below.

(D.2.3) The reinforcement required by (D.2) shall be that provided by any combination of areas A_1, A_2, A_3, A_4, and A_5, as defined below and illustrated in Fig. 104.3.1 (D) where

A_1 = area provided by excess pipe wall in the run
= $(2d_2 - d_1)(T_h - t_{mh})$

A_2 = area, in.^{2} (mm^2), provided by excess pipe wall in the branch for a distance L_4 above the run
= $2L_4\,(T_b - t_{mb})/\sin\alpha$

A_3 = area provided by deposited weld metal beyond the outside diameter of the run and branch, and for fillet weld attachments of rings, pads, and saddles

A_4 = are provided by a reinforcing ring, pad, or integral reinforcement. The value of A_4 may be taken in the same manner in which excess header metal is considered, provided the weld completely fuses the branch pipe, run pipe, and ring or pad, or integral reinforcement. For welding branch connections refer to para. 127.4.8.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:13 2005

A_5 = area provided by a saddle on right angle connections
= (O.D. of saddle − D_{ob})t_r

Portions of the reinforcement area may be composed of materials other than those of the run pipe, but if the allowable stress of these materials is less than that for the run pipe, the corresponding calculated reinforcement area provided by this material shall be reduced in the ratio of the allowable stress being applied to the reinforcement area. No additional credit shall be taken for materials having higher allowable stress values than the run pipe.

(D.2.4) Reinforcement Zone. The reinforcement zone is a parallelogram whose width shall extend a distance d_2 on each side of the center line of the branch pipe, and whose altitude shall start at the inside surface of the run pipe and extend to a distance L_4 from the outside surface of the run pipe.

(D.2.5) Reinforcement of Multiple Openings. It is preferred that multiple branch openings be spaced so that their reinforcement zones do not overlap. If closer spacing is necessary, the following requirement shall be met. The two or more openings shall be reinforced in accordance with (D.2), with a combined reinforcement that has a strength equal to the combined strength of the reinforcement that would be required for the separate openings. No portion of the cross section shall be considered as applying to more than one opening, or be evaluated more than once in a combined area.

When more than two adjacent openings are to be provided with a combined reinforcement, the minimum distance between centers of any two of these openings should preferably be at least $1\frac{1}{2}$ times their average diameter, and the area of reinforcement between them shall be at least equal to 50% of the total required for these two openings.

(D.2.6) Rings, Pads, and Saddles. Reinforcement provided in the form of rings, pads, or saddles shall not be appreciably narrower at the side than at the crotch.

A vent hole shall be provided at the ring, pad, or saddle to provide venting during welding and heat treatment. Refer to para. 127.4.8(E).

Rings, pads, or saddles may be made in more than one piece, provided the joints between pieces have full thickness welds, and each piece is provided with a vent hole.

(D.2.7) Other Designs. The adequacy of designs to which the reinforcement requirements of para. 104.3 cannot be applied shall be proven by burst or proof tests on scale models or on full size structures, or by calculations previously substantiated by successful service of similar design.

(E) Branch Connections Subject to External Pressure Requiring Reinforcement. The reinforcement area in square inches (square millimeters) required for branch connections subject to external pressure shall be

$$0.5t_{mh}d_1\ (2 - \sin\alpha)$$

Procedures established heretofore for connections subject to internal pressure shall apply for connections subject to external pressure provided that D_{oh}, D_{ob}, and t_r are reduced to compensate for external corrosion, if required by design conditions.

(F) Branch Connections Subject to External Forces and Moments. The requirements of the preceding paragraphs are intended to assure safe performance of a branch connection subjected only to pressure. However, when external forces and moments are applied to a branch connection by thermal expansion and contraction, by dead weight of piping, valves, and fittings, covering and contents, or by earth settlement, the branch connection shall be analyzed considering the stress intensification factors as specified in Appendix D. Use of ribs, gussets, and clamps designed in accordance with para. 104.3.4 is permissible to stiffen the branch connection, but their areas cannot be counted as contributing to the required reinforcement area of the branch connection.

(G) Extruded Outlets Integrally Reinforced

(G.1) The following definitions, modifications, notations, and requirements are specifically applicable to extruded outlets. The designer shall make proper wall thickness allowances in order that the required minimum reinforcement is assured over the design life of the system.

(G.2) Definition. An extruded outlet header is defined as a header in which the extruded lip at the outlet has an altitude above the surface of the run which is equal to or greater than the radius of curvature of the external contoured portion of the outlet; i.e., $h_o \geq r_o$. See nomenclature and Fig. 104.3.1(G).

(G.3) These rules apply only to cases where the axis of the outlet intersects and is perpendicular to the axis of the run. These rules do not apply to any nozzle in which additional nonintegral material is applied in the form of rings, pads, or saddles.

(G.4) The notation used herein is illustrated in Fig. 104.3.1(G). All dimensions are in inches (millimeters).

d = outside diameter of branch pipe
d_b = corroded internal diameter of branch pipe
D = outside diameter of run

(3) Sketch is drawn for condition where $k = 1.00$.

FIG. 104.3.1(G) REINFORCED EXTRUDED OUTLETS

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:13 2005

d_r = corroded internal diameter of run

d_c = corroded internal diameter of extruded outlet measured at the level of the outside surface of the run

h_o = height of the extruded lip. This must be equal to or greater than r_o except as shown in (G.4.2) below.

L_8 = altitude of reinforcement zone
= $0.7\sqrt{dT_o}$

$t_{mb} - A$ = required thickness of branch pipe according to wall thickness Formula (3) or (3A) in para. 104.1.2(A), but not including any thickness for corrosion

$t_b - A$ = actual thickness of branch wall not including corrosion allowance

$t_{mh} - A$ = required thickness of the run according to the Formula (3) or (3A) in para. 104.1.2(A), but not including any allowance for corrosion

$t_h - A$ = actual thickness of run wall, not including the corrosion allowance

T_o = corroded finished thickness of extruded outlet measured at a height equal to r_o above the outside surface of the run

r_1 = half width of reinforcement zone (equal to d_c)

r_o = radius of curvature of external contoured portion of outlet measured in the plane containing the axes of the run and branch. This is subject to the following limitations.

(G.4.1) Minimum Radius. This dimension shall not be less than $0.05d$ except that on branch diameters larger than NPS 30, it need not exceed 1.50 in. (38 mm).

(G.4.2) Maximum Radius. For outlet pipe sizes 6 in. nominal and larger, this dimension shall not exceed $0.10d + 0.50$ in. ($0.10d + 12.7$ mm). For outlet pipe sizes less than NPS 6, this dimension shall not be greater than 1.25 in. (32 mm).

(G.4.3) When the external contour contains more than one radius, the radius of any arc sector of approximately 45 deg shall meet the requirements of (G.4.1) and (G.4.2) above. When the external contour has a continuously varying radius, the radius of curvature at every point on the contour shall meet the requirements of (G.4.1) and (G.4.2) above.

(G.4.4) Machining other than grinding for weld cleanup shall not be employed in order to meet the above requirements.

(G.5) Required Area. The required area is defined as

$$A_7 = K\,(t_{mh} - A)\,d_c$$

where K shall be taken as follows.

For d/D greater than 0.60,

$$K = 1.00$$

For d/D greater than 0.15 and not exceeding 0.60,

$$K = 0.6 + \tfrac{2}{3}\,d/D$$

For d/D equal to or less than 0.15,

$$K = 0.70$$

The design must meet criteria that the reinforcement area defined in (G.6) below is not less than the required area.

(G.6) Reinforcement Area. The reinforcement area shall be the sum of areas

$$A_1 + A_2 + A_4$$

as defined below.

(G.6.1) Area A_1 is the area lying within the reinforcement zone resulting from any excess thickness available in the run wall.

$$A_1 = d_c(t_n - t_{mh})$$

(G.6.2) Area A_2 is the area lying within the reinforcement zone resulting from any excess thickness available in the branch pipe wall.

$$A_2 = 2L_8(t_b - t_{mb})$$

(G.6.3) Area A_4 is the area lying within the reinforcement zone resulting from excess thickness available in the extruded outlet lip.

$$A_4 = 2r_o\,[T_o - (t_b - A)]$$

(G.7) Reinforcement of Multiple Openings. It is pre-

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:14 2005

ferred that multiple branch openings be spaced so that their reinforcement zones do not overlap. If closer spacing is necessary, the following requirements shall be met. The two or more openings shall be reinforced in accordance with (G) with a combined reinforcement that has a strength equal to the combined strength of the reinforcement that would be required for separate openings. No portion of the cross section shall be considered as applying to more than one opening, or be evaluated more than once in a combined area.

(G.8) In addition to the above, the manufacturer shall be responsible for establishing and marking on the section containing extruded outlets, the design pressure and temperature. The manufacturer's name or trademarks shall be marked on the section.

104.3.3 Miters. Miter joints, and the terminology related thereto, are described in Appendix D. A widely spaced miter with

$$\theta < 9\sqrt{\frac{t_n}{r}}\ \text{deg}$$

shall be considered to be equivalent to a girth buttwelded joint, and the rules of this paragraph do not apply. Miter joints, and fabricated pipe bends consisting of segments of straight pipe welded together, with θ equal to or greater than this calculated value may be used within the limitations described below.

(A) Pressure shall be limited to 10 psi (70 kPa) under the following conditions:

(A.1) the assembly includes a miter weld with $\theta >$ 22.5 deg, or contains a segment which has a dimension

$$B < 6t_n$$

(A.2) the thickness of each segment of the miter is not less than that determined in accordance with para. 104.1;

(A.3) the contained fluid is nonflammable, nontoxic, and incompressible, except for gaseous vents to atmosphere;

(A.4) the number of full pressure cycles is less than 7000 during the expected lifetime of the piping system; and

(A.5) full penetration welds are used in joining miter segments.

(B) Pressure shall be limited to 100 psi (700 kPa) under the conditions defined in (A.2), (A.3), (A.4), and (A.5) above, in addition to the following:

(B.1) the angle θ does not exceed 22.5 deg; and

(B.2) the assembly does not contain any segment which has a dimension

$$B < 6t_n$$

(C) Miters to be used in other services or at design pressures above 100 psi (700 kPa) shall meet the requirements of para. 104.7.

(C.1) When justification under para. 104.7 is based on comparable service conditions, such conditions must be established as comparable with respect to cyclic as well as static loadings.

(C.2) When justification under para. 104.7 is based on an analysis, that analysis and substantiating tests shall consider the discontinuity stresses which exist at the juncture between segments; both for static (including brittle fracture) and cyclic internal pressure.

(C.3) The wall thickness t_s of a segment of a miter shall not be less than specified in (C.3.1) or (C.3.2) below, depending on the spacing.

(C.3.1) For closely-spaced miter bends (see Appendix D for definition)

$$t_s = t_m \frac{2 - r/R}{2(1 - r/R)}$$

(C.3.2) For widely-spaced miters (see Appendix D for definition)

$$t_s = t_m(1 + 0.64\sqrt{r/t_s}\tan\theta)$$

(the above equation requires an iterative or quadratic solution for t_s).

104.3.4 Attachments. External and internal attachments to piping shall be designed so as not to cause flattening of the pipe, excessive localized bending stresses, or harmful thermal gradients in the pipe wall. It is important that such attachments be designed to minimize stress concentrations in applications where the number of stress cycles, due either to pressure or thermal effect, is relatively large for the expected life of the equipment.

104.4 Closures

104.4.1 General. Closures for power piping systems shall meet the applicable requirements of this Code and shall comply with the requirements described in (A) or (B) below. Closures may be made:

(A) by use of closure fittings, such as threaded or welded plugs, caps, or blind flanges, manufactured in

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:14 2005

accordance with standards listed in Table 126.1, and used within the specified pressure-temperature ratings; or

(B) in accordance with the rules contained in the ASME Boiler and Pressure Vessel Code, Section I, Power Boilers, PG-31, or Section VIII, Pressure Vessels, Division 1, UG-34 and UW-13, calculated from

$$t_m = t + A$$

where

t = pressure design thickness, calculated for the given closure shape and direction of loading using appropriate equations and procedures in Section I or Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code

The definition of A and the symbols used in determining t shall have the definitions shown herein, instead of those given in the ASME Boiler and Pressure Vessel Code.

Attachment of a welded flat permanent closure with only a single fillet weld is not permitted.

104.4.2 Openings in Closures. Openings in closures may be made by welding, extruding, or threading. Attachment to the closure shall be in accordance with the limitations provided for such connections in para. 104.3.1 for branch connections. If the size of the opening is greater than one-half of the inside diameter of the closure, the opening shall be designed as a reducer in accordance with para. 104.6.

Other openings in closures shall be reinforced in accordance with the requirements of reinforcement for a branch connection. The total cross-sectional area required for reinforcement in any plane passing through the center of the opening and normal to the surface of the closure shall not be less than the quantity of d_5t, where

d_5 = diameter of the finished opening, in. (mm), and t as defined in (B) above

104.5 Pressure Design of Flanges and Blanks

104.5.1 Flanges — General

(A) Flanges of sizes NPS 24 and smaller, that are manufactured in accordance with ASME B16.1 and B16.5, shall be considered suitable for use at the primary service ratings (allowable pressure at service temperature) except the slip-on flanges to ASME B16.5 shall be limited in application to no higher than Class 300 primary pressure service rating. Refer to para. 127.4.4.

For flanges larger than NPS 24, and manufactured in accordance with the Specifications and Standards listed in Table 126.1, the designer is cautioned about the dimensionally different designs that are available, as well as the limitations of their application.

Flanges not made in accordance with the Specifications and Standards listed in Table 126.1 shall be designed in accordance with Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code, except that the requirements for fabrication, assembly, inspection, and testing, and the pressure and temperature limits for materials of this Code for Pressure Piping shall govern. Certain notations used in the ASME Code, namely, P, S_a, S_b, and S_f, shall have the meanings described below instead of those given in the ASME Code. All other notations shall be as defined in the ASME Code.

P = design pressure, psi (kPa) (see paras. 101.2.2 and 101.2.4)

S_a = bolt design stress at atmospheric temperature, psi (kPa)

S_b = bolt design stress at design temperature, psi (kPa)

S_f = allowable stress for flange material or pipe, psi (kPa) (see para. 102.3.1 and Allowable Stress Tables) (stress values converted from MPa to kPa)

For certain specific applications see the limitations of paras. 122.1.1 (F), (G), and (H).

(B) These flange design rules are not applicable to flat face designs employing full face gaskets which extend beyond the bolts.

(C) The bolt design stress in (A) above shall be as established in Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code, Appendix P for ferrous materials.

(D) Application of bolting materials for flanged joints is covered in para. 108.5.

104.5.2 Blind Flanges

(A) Blind flanges manufactured in accordance with the standards listed in Table 126.1 shall be considered suitable for use at the pressure-temperature rating specified by such Standards.

(B) The required thickness of blind flanges not manufactured in accordance with standards in Table 126.1 shall be calculated from Formula (6).

$$t_m = t + A \qquad (6)$$

where

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:14 2005

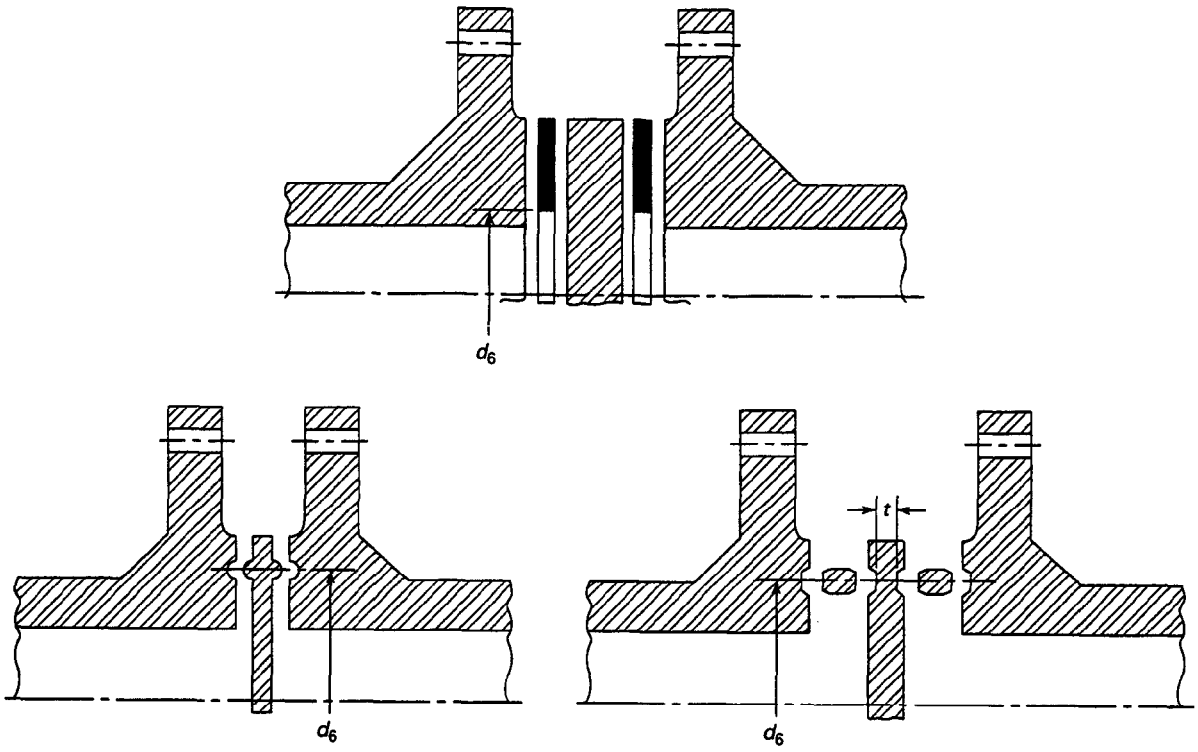

FIG. 104.5.3 TYPES OF PERMANENT BLANKS

t = pressure design thickness as calculated for the given style of blind flange from the appropriate equations for bolted flat cover plates in Section I of the ASME Boiler and Pressure Vessel Code. Certain notations used in these equations, namely, P and SE [see para. 104.1.2(A), footnote 1], shall be considered to have the meanings described in para. 104.1.2(A) instead of those given in the ASME Code. All other notations shall be as defined in the ASME Code.

104.5.3 Blanks

(A) The required thickness of permanent blanks (see Fig. 104.5.3) shall be calculated from the formula

$$t_m = t + A$$

where

t = pressure design thickness as calculated from Formula (7)

$$= d_6\sqrt{\frac{3P}{16SE}} \quad (7)$$

See para. 104.1.2(A), footnote 1.

d_6 = inside diameter of gasket for raised or flat (plain) face flanges, or the gasket pitch diameter for retained gasketed flanges, in. (mm)

(B) Blanks to be used for test purposes only shall have a minimum thickness not less than the pressure design thickness t specified above except that P shall be not less than the test pressure and SE [see para. 104.1.2(A), footnote 1] may be taken as the specified minimum yield strength of the blank material if the test fluid is incompressible.

(C) Attachment of a welded flat permanent blank with only a single fillet weld is not permitted.

104.6 Reducers

Flanged reducer fittings manufactured in accordance with the Standards listed in Table 126.1 shall be considered suitable for use at the specified pressure-temperature ratings. Where butt welding reducers are

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:15 2005

made to a nominal pipe thickness, the reducers shall be considered suitable for use with pipe of the same nominal thickness.

104.7 Other Pressure-Containing Components

104.7.1 Pressure-containing components manufactured in accordance with the standards listed in Table 126.1 shall be considered suitable for use under normal operating conditions at or below the specified pressure-temperature ratings. However, the user is cautioned that where certain standards or manufacturers may impose more restrictive allowances for variation from normal operation than those established by this Code, the more restrictive allowances shall apply.

104.7.2 Specially Designed Components. The pressure design of components not covered by the standards listed in Table 126.1 or for which design formulas and procedures are not given in this Code shall be based on calculations consistent with the design criteria of this Code. These calculations shall be substantiated by one or more of the means stated in (A), (B), (C), and (D) below:

(A) extensive, successful service experience under comparable conditions with similarly proportioned components of the same or similar material:

(B) experimental stress analysis, such as described in the ASME Boiler and Pressure Vessel Code, Section VIII, Division 2, Appendix 6;

(C) proof test in accordance with either ASME B16.9, MSS SP-97, or the ASME Boiler and Pressure Vessel Code, Section I. A-22; and

(D) detailed stress analysis, such as finite element method, in accordance with the ASME Boiler and Pressure Vessel Code, Division 2, Appendix 4, except that the basic material allowable stress from the Allowable Stress Tables of Appendix A shall be used in place of S_m.

For any of (A) through (D) above, it is permissible to interpolate between sizes, wall thicknesses, and pressure classes and to determine analogies among related materials.

Calculations and documentation showing compliance with this paragraph shall be available for the owner's approval, and, for boiler external piping, they shall be available for the Authorized Inspector's review.

104.8 Analysis of Piping Components

To validate a design under the rules in this paragraph, the complete piping system must be analyzed between anchors for the effects of thermal expansion, weight, other sustained loads, and other occasional loads. Each component in the system must meet the limits in this paragraph. For pipe and fittings, the pressure term in Eqs. (11) and (12) may be replaced with the alternative term for S_{lp} as defined in para. 102.3.2(D). The pressure term in Eqs. (11) and (12) may not apply for bellows and expansion joints. When evaluating stresses in the vicinity of expansion joints, consideration must be given to actual cross-sectional areas that exist at the expansion joint.

104.8.1 Stress due to Sustained Loads. The effects of pressure, weight, and other sustained mechanical loads shall meet the requirements of Eq. (11). 01

English units

$$S_L = \frac{PD_o}{4t_n} + \frac{0.75\ iM_A}{Z} \le 1.0\ S_h \qquad (11A)$$

Metric units

$$S_L = \frac{PD_o}{4t_n} + \frac{1000\ (0.75i)M_A}{Z} \le 1.0\ S_h \qquad (11B)$$

where

M_A = resultant moment loading on cross section due to weight and other sustained loads, in-lb (mm-N) (see para. 104.8.4)

Z = section modulus, in.^{3} (mm^3) (see para. 104.8.4)

i = stress intensification factor (see Appendix D). The product $0.75i$ shall never be taken as less than 1.0.

S_L = sum of the longitudinal stresses due to pressure, weight, and other sustained loads

104.8.2 Stress due to Occasional Loads. The effects of pressure, weight, other sustained loads, and occasional loads including earthquake must meet the requirements of Eq. (12). 01

English units

$$\frac{PD_o}{4t_n} + \frac{0.75iM_A}{Z} + \frac{0.75iM_B}{Z} \le k\ S_h \qquad (12A)$$

Metric units

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:15 2005

$$\frac{PD_o}{4t_n} + \frac{1000(0.75i)M_A}{Z} + \frac{1000(0.75i)M_B}{Z} \le k\,S_h \quad (12B)$$

Terms same as para. 104.8.1 except

k = 1.15 for occasional loads acting for no more than 8 hr at any one time and no more than 800 hr/year [see para. 102.3.3(A)]

k = 1.2 for occasional loads acting for no more than 1 hr at any one time and no more than 80 hr/year [see para. 102.3.3(A)]

M_B = resultant moment loading on cross section due to occasional loads [see para. 102.3.3(A)], such as thrusts from relief/safety valve loads, from pressure and flow transients, and earthquake (see para. 104.8.4). If calculation of moments due to earthquake is required, use only one-half the earthquake moment range. Effects of anchor displacement due to earthquake may be excluded from Eq. (12) if they are included in Eq. (13), in.-lb.

01 **104.8.3 Thermal Expansion Stress Range.** The effects of thermal expansion shall meet the requirements of Eq. (13).

English units

$$S_E = \frac{iM_C}{Z} \le S_A + f(S_h - S_L) \quad (13A)$$

Metric units

$$S_E = \frac{1000(iM_c)}{Z} \le S_A + f(S_h - S_L) \quad (13B)$$

Terms same as para. 104.8.1 except

M_C = range of resultant moments due to thermal expansion. Also include moments effects of anchor displacement due to earthquake if anchor displacement effects were omitted from Eq. (12) (see para. 104.8.4).

f = stress range reduction factor for cyclic conditions for total number N of full temperature cycles over total number of years during which system is expected to be in operation, from Table 102.3.2(C)

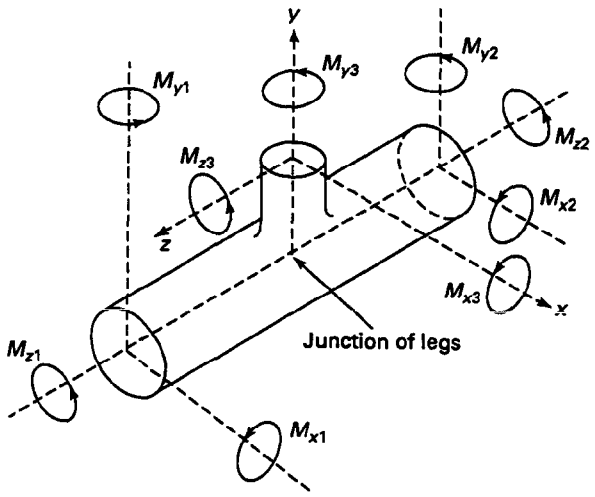

FIG. 104.8.4

104.8.4 Moments and Section Modulus

(A) For purposes of Eqs. (11), (12), and (13), the resultant moments for straight through components, curved pipe, or welding elbows may be calculated as follows:

$$M_j = (M_{xj}^2 + M_{yj}^2 + M_{zj}^2)^{1/2}$$

where

j = A, B, or C as defined in paras. 104.8.1, 104.8.2, and 104.8.3

Z = section modulus of piping, in.^{3} (mm^3)

(B) For full outlet branch connections, calculate the resultant moment of each leg separately in accordance with (A) above. Use Z, section modulus, in Eqs. (11) through (13) as applicable to branch or run pipe. Moments are taken at the junction point of the legs. See Fig. 104.8.4.

(C) For reduced outlets, calculate the resultant moment of each leg separately in accordance with (A) above. Moments are to be taken at the junction point of the legs, unless the designer can demonstrate the validity of a less conservative method. See Fig. 104.8.4. For the *reduced outlet branch*, except for branch connections covered by Fig. D-1:

$$M_A,\ M_B,\ M_C = \sqrt{M_{x3}^2 + M_{y3}^2 + M_{z3}^2}$$

and

Z = $\pi r_b^2 t_e$ (effective section modulus)

r_b = branch mean cross-sectional radius, in. (mm)

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:15 2005

t_e = effective branch wall thickness, in. (mm)
= lesser of t_{nh} or it_{nb} in Eq. (13) or lesser of t_{nh} or $0.75it_{nb}$, where $0.75i \geq 1.0$, in Eqs. (11) and (12)

For the *reduced outlet branch connections covered by Fig. D-1:*

$$M_A, M_B, M_C = \sqrt{M_{x3}^2 + M_{y3}^2 + M_{z3}^2}$$

and

$$Z = \pi r'^2_m T_b$$

If L_1 in Fig. D-1 sketches (a), (b), and (c) equals or exceeds $0.5\sqrt{r_i T_b}$, then r'_m can be taken as the radius to the center of T_b when calculating the section modulus and the stress intensification factor. For such a case the transition between branch pipe and nozzle must be evaluated separately from the branch connection.

For the *main run outlets:*

$$M_A, M_B, M_C = \sqrt{M_{x1}^2 + M_{y1}^2 + M_{z1}^2}$$

and

$$M_A, M_B, M_C = \sqrt{M_{x2}^2 + M_{y2}^2 + M_{z2}^2}$$

and

Z = section modulus of pipe, in.^{3} (mm^3)

PART 3
SELECTION AND LIMITATIONS OF PIPING COMPONENTS

105 PIPE

105.1 General

Pipe conforming to the standards and specifications listed in Appendix A shall be used within the range of temperatures for which allowable stresses are given within the limitations specified herein.

105.2 Metallic Pipe

105.2.1 Ferrous Pipe

(A) Furnace butt welded steel pipe shall not be used for flammable, combustible or toxic fluids.

(B) Cast iron pipe may be used for design pressures within the ratings established by the standards and specifications listed in Tables 126.1 and A-5 and Notes thereto, and the limitations herein and in para. 124.4. Cast iron pipe shall not be used for flammable, combustible, or toxic fluids.

105.2.2 Nonferrous Pipe

(A) Copper and brass pipe for water and steam service may be used for design pressures up to 250 psi (1750 kPa) and for design temperatures to 406°F (208°C).

(B) Copper and brass pipe for air may be used in accordance with the allowable stresses given in the Allowable Stress Tables.

(C) Copper tubing may be used for dead-end instrument service with the limitations stated in para. 122.3.2(D).

(D) Copper, copper alloy, or aluminum alloy pipe or tube may be used under the conditions stated in para. 124.7. Copper, copper alloy, or aluminum pipe or tube shall not be used for flammable, combustible, or toxic fluids except as permitted in paras. 122.7 and 122.8.

105.3 Nonmetallic Pipe 01

(A) Plastic pipe may be used for water and nonflammable liquids where experience or tests have demonstrated that the plastic pipe is suitable for the service conditions, and the pressure and temperature conditions are within the manufacturer's recommendations. Until such time as mandatory rules are established for these materials, pressure shall be limited to 150 psi (1000 kPa) and temperature to 140°F (60°C) for water service. Pressure and temperature limits for other services shall be based on the hazards involved, but in no application shall they exceed 150 psi (1000 kPa) and 140°F (60°C). For nonmandatory rules for nonmetallic piping, see Appendix III of this Code.

(B) Reinforced thermosetting resin pipe may be used, in addition to the services listed in para. 105.3(A), in buried flammable and combustible liquid service subject to the limitations described in para. 122.7.3(F).

(C) Reinforced concrete pipe may be used in accordance with the specifications listed in Table 126.1 for water service up to 150°F (65°C).

(D) A flexible nonmetallic pipe or tube assembly may be used in applications where:

(a) satisfactory service experience exists;

(b) the pressure and temperature conditions are within the manufacturer's recommendations; and

(c) the conditions described in paras. 104.7, 124.7, and 124.8 are met.

(E) Polyethylene pipe may be used, in addition to

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:16 2005

the service listed in para. 105.3(A), in buried flammable and combustible liquid and gas service subject to the limitations described in paras. 122.7.2(D) and 122.8.1(B.4).

106 FITTINGS, BENDS, AND INTERSECTIONS

106.1 Fittings

(A) Threaded, flanged, grooved and shouldered socket-welding, buttwelding, compression, and solder-joint fittings made in accordance with the applicable standards in Table 126.1 may be used in power piping systems within the material, size, pressure, and temperature limitations of those standards, and within any further limitations specified in this Code. Material for fittings in flammable, combustible, or toxic fluid systems shall in addition conform to the requirements of paras. 122.7 and 122.8.

(B) Fittings not covered by the Standards listed in Table 126.1 may be used if they conform to para. 104.7.

(C) Cast buttwelding steel fittings not covered by the dimensional standards listed in Table 126.1 may be used up to the manufacturer's pressure and temperature ratings, provided they are radiographed in accordance with the method of ASTM E 142 and meet the acceptance requirements of ASTM E 446, E 186, and E 280 as applicable for the thickness being radiographed.

(D) Fabricated ends for grooved and shouldered type joints are acceptable, provided they are attached by full penetration welds, double fillet welds, or by threading. Fabricated ends attached by single fillet welds are not acceptable.

106.1.1 Bell and Spigot Fittings. Bell and spigot fittings complying with applicable standards listed in Table 126.1 may be used for cold water and drainage service.

106.2 Bends and Intersections

Bends and extruded branch connections may be used when designed in accordance with the provisions of paras. 104.2 and 104.3, respectively. Miters may be used within the limitations of para. 104.3.3.

106.3 Pipe Couplings

(A) Cast iron and malleable iron pipe couplings shall be limited in application as referenced in paras. 124.4 and 124.5, respectively.

(B) Straight thread couplings shall not be used.

106.4 Flexible Metal Hose Assembly

(A) Flexible metal hose assemblies may be used to provide flexibility in a piping system, to isolate or control vibration, or to compensate for misalignment. The design conditions shall be in accordance with para. 101 and within the limitations of the assembly as recommended by the manufacturer. The basis for their application shall include the following service conditions: thermal cycling, bend radius, cycle life, and the possibility of corrosion and erosion. Installation shall be limited to a single-plane bend, free from any torsion effects during service conditions and nonoperating periods. Type of end-connector components shall be consistent with the requirements of this Code.

(B) A flexible metal hose assembly, consisting of one continuous length of seamless or butt welded tube with helical or annular corrugations, is not limited as to application in piping systems which are within the scope of this Code, provided that the conditions described in (A) above are met. For application subject to internal pressure the flexible element shall be contained within one or more separate layers of braided metal permanently attached at both coupling ends by welding or brazing. For application in toxic fluid systems, it is recommended that the designer also review the standards published by the relevant fluid industry for any additional safety and materials requirements that may be necessary.

(C) A flexible metal hose assembly consisting of wound interlocking metal strips may be applied to atmospheric vent systems only and shall not be used in systems which convey high temperature, flammable, toxic, or searching-type fluids. Where applicable, as determined by the designer and within the limitations described in para. 122.6 and those imposed by the manufacturer, this type of hose assembly may be used at pressure relieving devices.

107 VALVES

107.1 General

(A) Valves complying with the standards and specifications listed in Table 126.1 shall be used within the specified pressure-temperature ratings.

(B) Valves not complying with (A) above shall be of a design, or equal to the design, which the manufacturer recommends for the service as stipulated in para. 102.2.2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:16 2005

(C) Some valves are capable of sealing simultaneously against a pressure differential between an internal cavity of the valve and the adjacent pipe in both directions. Where liquid is entrapped in such a valve and is subsequently heated, a dangerous rise in pressure can result. Where this condition is possible, the Owner shall provide means in design, installation, and/or operation to assure that the pressure in the valve shall not exceed the rated pressure for the attained temperature. A relief device used solely for the over-pressure protection from such entrapped fluid and conforming to (A) or (B) above need not comply with the requirements of para. 107.8. Any penetration of the pressure retaining wall of the valve shall meet the requirements of this Code.

(D) Only valves designed such that the valve stem is retained from blow-out by an assembly which functions independently of the stem seal retainer shall be used.

(E) Materials used for pressure retention for valves in flammable, combustible, or toxic fluid systems shall in addition conform to the requirements of paras. 122.7 and 122.8.

107.2 Marking

Each valve shall bear the manufacturer's name or trademark and reference symbol to indicate the service conditions for which the manufacturer guarantees the valve. The marking shall be in accordance with ASME B16.5 and B16.34.

107.3 Ends

Valves may be used with flanged, threaded, butt welding, socket welding, or other ends in accordance with applicable standards as specified in para. 107.1(A).

107.4 Stem Threads

Stem threads of valves may be internal or external with reference to the valve bonnet. Outside screw and yoke design shall be used for valves NPS 3 and larger for pressures above 600 psi (4150 kPa).

107.5 Bonnet Joints

Bonnet joints may be of flanged, welded, pressure seal, union type, or other design, except that screwed bonnet connections in which the seal depends on a steam tight threaded joint shall not be permitted as source valves in steam service at pressures above 250 psi (1750 kPa).

107.6 Bypasses

Sizes of bypasses shall be in accordance with MSS SP-45 as a minimum standard. Pipe for bypasses shall be at least schedule 80 seamless, and of a material of the same nominal chemical composition and physical properties as that used for the main line. Bypasses may be integral or attached.

107.8 Safety, Safety Relief, and Relief Valves

107.8.1 General. Safety, safety relief, and relief valves shall conform to the requirements specified in this Code for flanges, valves, and fittings for the pressures and temperatures to which they may be subjected.

107.8.2 Safety, Safety Relief, and Relief Valves on Boiler External Piping. Safety, safety relief, and relief valves on boiler external piping shall be in accordance with para. 122.1.7(D.1) of this Code.

107.8.3 Safety, Safety Relief, and Relief Valves on Nonboiler External Piping. Safety, safety relief, and relief valves on nonboiler external piping (except for reheat safety valves) shall be in accordance with the requirements of the ASME Boiler and Pressure Vessel Code, Section VIII, Division 1, UG-126 through UG-133. Reheat safety valves shall be in accordance with the requirements of the ASME Boiler and Pressure Vessel Code, Section I, PG-67 through PG-73.

107.8.4 Nonmandatory Appendix. For nonmandatory rules for the design of safety valve installations, see Appendix II of this Code.

108 PIPE FLANGES, BLANKS, FLANGE FACINGS, GASKETS, AND BOLTING

108.1 Flanges

Flanges shall conform to the design requirements of para. 104.5.1 or to the standards listed in Table 126.1. They may be integral or shall be attached to pipe by threading, welding, brazing, or other means within the applicable standards specified in Table 126.1.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:16 2005

108.2 Blanks

Blanks shall conform to the design requirements of para. 104.5.3.

108.3 Flange Facings

Flange facings shall be in accordance with the applicable standards listed in Tables 126.1 and 112. When bolting Class 150 standard steel flanges to flat face cast iron flanges, the steel flange shall be furnished with a flat face. Steel flanges of Class 300 raised face standard may be bolted to Class 250 raised face cast iron.

108.4 Gaskets

Gaskets shall be made of materials which are not injuriously affected by the fluid or by temperature. They shall be in accordance with Table 112.

108.5 U. S. Customary Bolting

108.5.1 General

(A) Bolts, bolt studs, nuts, and washers shall comply with applicable standards and specifications listed in Table 126.1 and Table 112. Bolts and bolt studs shall extend completely through the nuts.

(B) Washers, when used under nuts, shall be of forged or rolled material with steel washers being used under steel nuts and bronze washers under bronze nuts.

(C) Nuts shall be provided in accordance with the requirements of the specification for the bolts and bolt studs.

(D) Alloy steel bolt studs shall be either threaded full length or provided with reduced shanks of a diameter not less than that at the root of the threads. They shall have ASME heavy hexagonal nuts. Headed alloy bolts shall not be used with other than steel or stainless steel flanges.

(E) All alloy steel bolt studs and carbon steel bolts or bolt studs and accompanying nuts shall be threaded in accordance with ASME B1.1 Class 2A for external threads and Class 2B for internal threads. Threads shall be the coarse-thread series except that alloy steel bolting $1\frac{1}{8}$ in. and larger in diameter shall be the 8-pitch-thread series.

(F) Carbon steel headed bolts shall have square, hex, or heavy hex heads (ANSI B18.2.1) and shall be used with hex or heavy hex nuts (ASME B18.2.2). For bolt sizes smaller than $\frac{3}{4}$ in., square or heavy hex heads and heavy hex nuts are recommended. For bolt sizes larger than $1\frac{1}{2}$ in., bolt studs with a hex or heavy hex nut on each end are recommended. For cast iron or bronze flanges using $\frac{3}{4}$ in. and larger carbon steel headed bolts, square nuts may be used.

108.5.2 For the various combinations of flange materials, the selection of bolting materials and related rules concerning flange faces and gaskets shall be in accordance with para. 108 and Table 112.

108.5.3 Bolting requirements for components not covered by para. 108.5.2 shall be in accordance with para. 102.2.2

108.6 Metric Bolting

108.6.1 General. The use of metric bolts, bolt studs, nuts, and washers shall conform to the general requirements of para. 108.5, but the following are allowed. 01

(A) Threads shall be in accordance with ASME B1.13M, M profile, with tolerance Class 6g for external threads and Class 6H for internal threads.

(B) Threads shall be the coarse-thread series for size M68 and smaller, and 6 mm fine-pitch for M70 and larger sizes, except that alloy steel bolting M30 and larger shall be the 3 mm fine-pitch.

(C) Nuts shall be heavy hex in accordance with ASME B18.2.4.6M. Headed bolts shall be either hex or heavy hex in accordance with ASME B18.2.3.5M and B18.2.3.6M, respectively. Heavy hex heads are recommended for headed bolt sizes M18 and smaller.

(D) Bolt studs are recommended in lieu of headed bolts for sizes M39 and larger.

(E) Metric bolting is not approved for boiler external piping applications.

108.6.2 Responsibilities When Specifying or Allowing Metric Bolting 01

(A) The piping designer is responsible for specifying the metric bolt size to be used with each class and size of flange.

(B) The designer shall ensure that the selected metric size will fit within the flange bolt holes, and that adequate space exists for bolt heads, nuts, and the assembly tool.

(C) In those instances where the selected metric bolt size is smaller in root thread area than the corresponding U.S. Customary size, the designer shall ensure that the selected size is capable of the required assembly torque and of producing the required gasket loading to adequately seal at design pressure. Further, the designer shall ensure sufficient contact area exists between the flange metal and both the nut and bolt head to withstand the required bolt loading. If not, larger bolting or a higher flange class shall be selected.

PART 4
SELECTION AND LIMITATIONS OF PIPING JOINTS

110 PIPING JOINTS

The type of piping joint used shall be suitable for the design conditions and shall be selected with consideration of joint tightness, mechanical strength, and the nature of the fluid handled.

111 WELDED JOINTS

111.1 General

Welded joints may be used in any materials allowed by this Code for which it is possible to qualify WPSs, welders, and welding operators in conformance with the rules established in Chapter V.

All welds shall be made in accordance with the applicable requirements of Chapter V.

111.2 Butt Welds

111.2.1 Design of Butt Welds. The design of butt welds shall include the evaluation of any expected joint misalignment [para. 127.3(C)], which may result from specification of joint geometries at variance with the recommendations of this Code.

111.2.2 Backing Rings for Butt Welds. If backing rings are used in services where their presence will result in severe corrosion or erosion, the backing ring shall be removed and the internal surface ground smooth. In such services, where it is impractical to remove the backing ring, consideration shall be given to welding the joint without a backing ring, or with a consumable type insert ring.

111.3 Socket Welds

111.3.1 Restrictions on size of socket welded components are given in paras. 104.3.1(B.4), 122.1.1(H), and 122.8.2(C). Special consideration should be given to further restricting the use of socket welded piping joints where temperature or pressure cycling or severe vibration is expected to occur or where the service may accelerate crevice corrosion.

111.3.2 Dimensions for sockets of socket welding components shall conform to ASME B16.5 for flanges and ASME B16.11 for fittings. Assembly of socket welded joints shall be made in accordance with para. 127.3(E).

111.3.3 A branch connection socket welded directly into the wall of the run pipe shall be in accordance with requirements of para. 104.3.1(B.4).

111.3.4 Drains and bypasses may be attached to a fitting or valve by socket welding, provided the socket depth, bore diameter, and shoulder thickness conform to the requirements of ASME B16.11.

111.4 Fillet Welds

Fillet welds shall have dimensions not less than the minimum dimensions shown in Figs. 127.4.4(B), 127.4.4(C), and 127.4.8(D).

111.5 Seal Welds

Seal welding of connections, including threaded joints, may be used to avoid joint leakage but the welding shall not be considered as contributing any strength to the joint. Also see para. 127.4.5. Seal welded threaded joints are subject to the limitations of para. 114.

112 FLANGED JOINTS

Flanged joints shall conform to paras. 108 and 110 and Table 112.

113 EXPANDED OR ROLLED JOINTS

Expanded or rolled joints may be used where experience or test has demonstrated that the joint is suitable for the design conditions and where adequate provisions are made to prevent separation of the joint.

114 THREADED JOINTS

Threaded joints may be used within the limitations specified in para. 106 and within the other limitations specified herein.

114.1

All threads on piping components shall be taper pipe threads in accordance with the applicable Standards listed in Table 126.1. Threads other than taper pipe threads may be used for piping components where tightness of the joint depends on a seal weld or a seating surface other than the threads, and where experience or test has demonstrated that such threads are suitable.

TABLE 112
PIPING FLANGE BOLTING, FACING, AND GASKET REQUIREMENTS (CONT'D)
Refer to Paras. 108, 110, and 112

Item	Flange A Mating With Flange B		Bolting	Flange Facings	Gaskets
	Flange A	Flange B			
(i)	Class 300 and higher classes, steel and stainless steel	Class 300 and higher classes, steel and stainless steel	(i)(1) "Low strength" [Notes (1), (2), and (5)]	(i)(1) Raised or flat on one or both flanges; large or small male and female; large or small tongue and groove	(i)(1) Flat ring nonmetallic to ASME B16.5, Para. 6.11 and Annex E, Group Ia material [Note (11)]
			(i)(2) "Higher strength" [Notes (3), (4), and (5)]	(i)(2) Raised or flat on one or both flanges; large or small male and female; large or small tongue and groove	(i)(2) Ring style to ASME B16.5, Para. 6.11 and Annex E [Notes (10) and (11)]
			(i)(3) "Higher strength" [Notes (3), (4), and (5)]	(i)(3) Ring joint	(i)(3) Ring joint to ASME B16.20
(j)	Class 800 cast iron	Class 800 cast iron	"Low strength" [Notes (1), (2), and (5)]	Raised or large male and female	Flat ring nonmetallic to ASME B16.21, Table 4

GENERAL NOTES:

(a) Bolting (including nuts), flange facing, and gasket selection (materials, dimensions, bolt stress, gasket factor, seating stress, etc.) shall be suitable for the flanges, service conditions, and hydrostatic tests. There shall be no overstressing of the gasket or flanges from the expected bolt loading or external bending loads.

(b) Unless otherwise stated, the flange facing described applies to both flanges A and B.

(c) For flanges other than to ASME B16.1, in sizes larger than NPS 24 (NPS 12 in Class 2500), gasket dimensions should be verified against the flanges specified (e.g., MSS SP-44 and API 605).

(d) The effective seating of a full face gasket shall extend to the outside edge of the flange. For flat or raised face flanges, a flat ring or ring style gasket shall be self-centering, extending to the inner edge of the bolt holes or bolts. Where the joint contains a cast iron, bronze, nonmetallic, or MSS SP-51 stainless steel flange, the effective gasket seating shall extend to the outside diameter of the gasket.

(e) Unconfined nonmetallic gaskets shall not be used on flat or raised face flanges if the expected normal operating pressure exceeds 720 psi (4950 kPa) or the temperature exceeds 750°F (400°C). Metal gaskets, spiral wound gaskets of metal with nonmetallic filler, and confined nonmetallic gaskets are not limited as to pressure or temperature provided the gasket materials are suitable for the maximum fluid temperatures.

(continued)

TABLE 112 (CONT'D)

NOTES:

(1) "Low strength" bolting shall conform to ASTM:

A 193, Grade B8A, B8CA, B8MA, or B8TA	A 307, Grade 8 [Bolting to A 307, Grade B shall not be used at temperatures greater than 400°F (200°C)]
A 193, Class 1, Grade B8, B8C, B8M, or B8T	A 320, Class 1, Grade B8, B8C, B8M, or B8T

(2) Nuts for "low strength" bolting shall conform to the grade of ASTM A 194 or A 563 as required by the bolting specification.

(3) "Higher strength" bolting shall conform to ASTM:

A 193, Grade B5, B6, B6X, B7, B7M, or B16	A 354, Grade BC or BD
A 193, Class 2, Grade B8, B8C, B8M, or B8T	A 437, Grade B4B, B4C, or B4D
A 320, Grade L7, L7A, L7B, L7C, or L43	
A 320, Class 2, Grade B8, B8C, B8F, B8M, or B8T	A 453, Grade 651 or 660

(4) Nuts for "higher strength" bolting shall conform to the grade of ASTM A 194, A 437, A 453, A 563, or A 564, as required by the bolting specification.

(5) For temperatures below −20°F (−29°C), bolting conforming to the ASTM A 320 classes and grades listed, respectively, in Note (3) "higher strength" and Note (1) "low strength" shall be used. For this bolting to ASTM A 320, Grades L7, L7A, L7B, L7C, and L43, the nuts shall conform to ASTM A 194, Grade 4 or 7 with impact requirements of A 320. For bolting to the other grades of A 320, the nuts shall conform to A 320.

(6) Additionally, for joints containing bronze flanges, nonferrous bolting conforming to the following may be used:

ASTM B 98, UNS C65100, C65500, and C66100; half hard; to 350°F (177°C) maximum	ASTM B 164, UNS N04400 and N04405; hot finish; 550°F (288°C) maximum
ASTM B 150, UNS C61400, to 500°F (260°C) maximum	ASTM B 164, UNS N04400, cold drawn, cold drawn and stress relieved, or cold drawn and stress equalized; and N04405, cold drawn, to 500°F (260°C) maximum
ASTM B 150, UNS C63000 and C64200, to 550°F (288°C) maximum	

(7) Where a flanged joint contains dissimilar materials (e.g., bronze flanges with steel bolting) and has a design temperature exceeding 300°F (149°C), the differences in coefficients of expansion shall be considered.

(8) For bronze flanges where "low strength" or nonferrous bolting is used, nonmetallic gaskets having seating stresses greater than 1600 psi shall not be used.

(9) For stainless steel flanges to MSS SP-51 and for nonmetallic flanges, preference shall be given to gasket materials having the lower minimum design seating stress as listed in ASME B16.5, Fig. E1, Group 1a.

(10) For items (d)(2), and (i)(2), where two flat face flanges are used in a joint and the gasket seating width (considering both the gasket and the flanges) is greater than that of an ASME B16.5 flange having a standard raised face, the gasket material shall conform to ASME B16.5, Annex E, Group 1a.

(11) Where asbestos sheet, fiber or filler material for gaskets is specified in ASME B16.5, this limitation shall not apply to ASME B31.1 applications. Any nonmetallic material suitable for the operating conditions may be used in lieu of asbestos provided the requirements of Table 112 are met.

01

TABLE 114.2.1

Maximum Nominal Size, in.	Maximum Pressure psi	Maximum Pressure kPa
3	400	2 750
2	600	4 150
1	1200	8 300
3/4 and smaller	1500	10 350

GENERAL NOTE: For instrument, control and sampling lines, refer to para. 122.3.6(A.5)

114.2.1 Threaded joints shall not be used where severe erosion, crevice corrosion, shock, or vibration is expected to occur, nor at temperatures over 925°F (495°C). Size limits for steam and hot water service [above 220°F (105°C)] shall be as listed in Table 114.2.1.

114.2.2 Threaded access holes with plugs, which serve as openings for radiographic inspection of welds, are not subject to the limitations of para. 114.2.1 and Table 114.2.1, provided their design and installation meets the requirement of para. 114.1. A representative type of access hole and plug is shown in PFI ES-16.

114.2.3 Threaded connections for insertion type fluid temperature determination, flow measurement, and sampling devices are not subject to the temperature limitation stated in para. 114.2.1 nor the pressure limitations stated in Table 114.2.1 provided that design and installation meet the requirements of paras. 104.3.1 and 114.1. At temperatures greater than 925°F (495°C) or at pressures greater than 1500 psi (10 350 kPa), these threaded connections shall be seal welded in accordance with para. 127.4.5. The design and installation of insertion type fluid temperature determination, flow measurement, and sampling devices shall be adequate to withstand the effects of the fluid characteristics, fluid flow, and vibration.

114.3

Pipe with a wall thickness less than that of standard weight of ASME B36.10M steel pipe shall not be threaded, regardless of service. For additional threading limitations for pipe used in:

(A) steam service over 250 psi (1750 kPa); or

(B) water service over 100 psi (700 kPa) and 220°F (105°C).

See para. 104.1.2(C.1).

115 FLARED, FLARELESS, AND COMPRESSION JOINTS

Flared, flareless, and compression type tubing fittings may be used for tube sizes not exceeding 2 in. (50 mm) O.D. within the limitations of applicable standards and specifications listed in Table 126.1.

In the absence of standards, specifications, or allowable stress values for the material used to manufacture the fitting, the designer shall determine that the type and the material of the fitting selected is adequate and safe for the design conditions in accordance with the following requirements.

(A) The pressure design shall meet the requirements of para. 104.7.

(B) A suitable quantity of the type, size, and material of the fittings to be used shall meet successful performance tests to determine the safety of the joint under simulated service conditions. When vibration, fatigue, cyclic conditions, low temperature, thermal expansion, or hydraulic shock are expected, the applicable conditions shall be incorporated in the test.

115.1

Fittings and their joints shall be compatible with the tubing with which they are to be used and shall conform to the range of wall thicknesses and method of assembly recommended by the manufacturer.

115.2

Fittings shall be used at pressure-temperature ratings not exceeding the recommendations of the manufacturer. Service conditions, such as vibration and thermal cycling, shall be considered in the application.

115.3

See para. 114.1 for requirements of threads on piping components.

115.4

Flareless fittings shall be of a design in which the gripping member or sleeve shall grip or bite into the outer surface of the tube with sufficient strength to hold the tube against pressure, but without appreciably distorting the inside tube diameter. The gripping member shall also form a pressure seal against the fitting body.

When using bite type fittings, a spot check shall be made for adequate depth of bite and condition of tubing by disassembling and reassembling selected joints.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:19 2005

Grip type fittings that are tightened in accordance with manufacturer's instructions need not be disassembled for checking.

116 CAULKED JOINTS

116.1

Caulked or leaded joints of the bell and spigot type which are caulked with lead and packing material may be used for cold water service.

116.2

Caulked joints may be used at pressures permitted for the pipe to which they are applied where provisions are made to prevent disengagement of the joints at bends and dead ends, and to support lateral reactions produced by branch connections or other causes.

117 BRAZED AND SOLDERED JOINTS

117.1

Brazed socket-type joints shall be made with suitable brazing alloys. The minimum socket depth shall be sufficient for the intended service. Brazing alloy shall either be end-fed into the socket or shall be provided in the form of a preinserted ring in a groove in the socket. The brazing alloy shall be sufficient to fill completely the annular clearance between the socket and the pipe or tube. The limitations of paras. 117.3(A) and (D) shall apply.

117.2

Soft soldered socket-type joints made in accordance with applicable standards listed in Table 126.1 may be used within their specified pressure-temperature ratings. The limitations in paras. 117.3 and 122.3.2(E.2.3) for instrument piping shall apply. The allowances of para. 102.2.4 do not apply.

117.3 Limitations

(A) Brazed socket-type joints shall not be used on systems containing flammable or toxic fluids in areas where fire hazards are involved.

(B) Soldered socket-type joints shall be limited to systems containing nonflammable and nontoxic fluids.

(C) Soldered socket-type joints shall not be used in piping subject to shock or vibration.

(D) Brazed or soldered joints depending solely upon a fillet, rather than primarily upon brazing or soldering material between the pipe and sockets, are not acceptable.

118 SLEEVE COUPLED AND OTHER PROPRIETARY JOINTS

Coupling type, mechanical gland type, and other proprietary joints may be used where experience or tests have demonstrated that the joint is safe for the operating conditions, and where adequate provision is made to prevent separation of the joint.

PART 5
EXPANSION, FLEXIBILITY, AND SUPPORTING

119 EXPANSION AND FLEXIBILITY

119.1 General

In addition to the design requirements for pressure, weight, and other loadings, power piping systems subject to thermal expansion or contraction or to similar movements imposed by other sources shall be designed in accordance with the requirements for the evaluation and analysis of flexibility and stresses specified herein.

119.2 Stress Range

Stresses caused by thermal expansion, when of sufficient initial magnitude, relax in the hot condition as a result of local yielding or creep. A stress reduction takes place and usually appears as a stress of reversed sign when the component returns to the cold condition. This phenomenon is designated as self-springing of the line and is similar in effect to cold springing. The extent of self-springing depends on the material, the magnitude of the initial expansion and fabrication stress, the hot service temperature and the elapsed time. While the expansion stress in the hot condition tends to diminish with time, the sum of the expansion strains for the hot and cold conditions during any one cycle remains substantially constant. This sum is referred to as the strain range; however, to permit convenient association with allowable stress, stress range is selected as the criterion for the thermal design of piping. The allowable stress range shall be determined in accordance with para. 102.3.2(C).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:19 2005

119.3 Local Overstrain

All the commonly used methods of piping flexibility analysis assume elastic behavior of the entire piping system. This assumption is sufficiently accurate for systems where plastic straining occurs at many points or over relatively wide regions, but fails to reflect the actual strain distribution in unbalanced systems where only a small portion of the piping undergoes plastic strain, or where, in piping operating in the creep range, the strain distribution is very uneven. In these cases, the weaker or higher stressed portions will be subjected to strain concentrations due to elastic follow-up of the stiffer or lower stressed portions. Unbalance can be produced:

(A) by use of small pipe runs in series with larger or stiffer pipe, with the small lines relatively highly stressed;

(B) by local reduction in size or cross section, or local use of a weaker material; or

(C) in a system of uniform size, by use of a line configuration for which the neutral axis or thrust line is situated close to the major portion of the line itself, with only a very small offset portion of the line absorbing most of the expansion strain.

Conditions of this type should preferably be avoided, particularly where materials of relatively low ductility are used; if unavoidable, they may be mitigated by the judicious application of cold spring.

It is recommended that the design of piping systems of austentic steel materials be approached with greater over-all care as to inspection, material selection, fabrication quality, erection, and elimination of local stress raisers.

119.5 Flexibility

Power piping systems shall be designed to have sufficient flexibility to prevent pipe movements from causing failure from overstress of the pipe material or anchors, leakage at joints, or detrimental distortion of connected equipment resulting from excessive thrusts and moments. Flexibility shall be provided by changes of direction in the piping through the use of bends, loops, or offsets; or provisions shall be made to absorb thermal movements by utilizing expansion, swivel, or ball joints, corrugated pipe, or flexible metal hose assemblies.

119.5.1 Expansion, Swivel, or Ball Joints, and Flexible Metal Hose Assemblies. Except as stated in para. 101.7.2, these components may be used where experience or tests have demonstrated that they are suitable for expected conditions of pressure, temperature, service, and cyclic life.

Restraints and supports shall be provided, as required, to limit movements to those directions and magnitudes permitted for specific joint or hose assembly selected.

119.6 Properties

Thermal expansion data and moduli of elasticity shall be determined from Appendix B and Appendix C, Tables C-1 and C-2, which cover more commonly used piping materials. For materials not included in these Tables, reference shall be to authoritative source data such as publications of the National Institute of Standards and Technology.

119.6.1 Thermal Expansion Range. The thermal expansion range shall be determined from Appendix B as the difference between the unit expansion shown for the highest metal temperature and that for the lowest metal temperature resulting from operating or shutdown conditions.

119.6.2 Moduli of Elasticity. The cold and hot moduli of elasticity E_c and E_h shall be as shown in Appendix C, Table C-1 for ferrous materials and Table C-2 for nonferrous materials, based on the temperatures established in para. 119.6.1.

119.6.3 Poisson's Ratio. Poisson's ratio, when required for flexibility calculations, shall be taken as 0.3 at all temperatures for all materials.

119.6.4 Stresses. Calculations for the stresses shall be based on the least cross section area of the component, using nominal dimensions at the location of local strain. Calculations for the thermal expansion stress range S_E shall be based on the modulus of elasticity E_c at room temperature.

119.7 Analysis

119.7.1 Method of Analysis. All piping shall meet the following requirements with respect to thermal expansion and flexibility:

(A) It shall be the designer's responsibility to perform an analysis unless the system meets one of the following criteria.

(A.1) The piping system duplicates a successfully operating installation or replaces a system with a satisfactory service record.

(A.2) The piping system can be adjudged adequate by comparison with previously analyzed systems.

(A.3) The piping system is of uniform size, has not

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:19 2005

more than two anchors and no intermediate restraints, is designed for essentially noncyclic service (less than 7000 total cycles), and satisfies the following approximate criterion:

(a) English Units

$$\frac{DY}{(L-U)^2} \le 0.03$$

(b) SI Units

$$\frac{DY}{(L-U)^2} \le 208.3$$

where

D = nominal pipe size, in. (mm)
Y = resultant of movements to be absorbed by pipe lines, in. (mm)
L = developed length of line axis, ft (m)
U = anchor distance (length of straight line joining anchors), ft (m)

WARNING: No general proof can be offered that this equation will yield accurate or consistently conservative results. It was developed for ferrous materials and is not applicable to systems used under severe cyclic conditions. It should be used with caution in configurations such as unequal leg U-bends (L/U > 2.5), or near straight "saw-tooth" runs, or for large diameter thin-wall pipe, or where extraneous displacements (not in the direction connecting anchor points) constitute a large part of the total displacement. There is no assurance that terminal reactions will be acceptably low, even if a piping system falls within the above limitations.

(B) All systems not meeting the above criteria, or where reasonable doubt exists as to adequate flexibility of the system, shall be analyzed by simplified, approximate, or comprehensive methods of analysis that are appropriate for the specific case.

(C) Approximate or simplified methods may be applied only if they are used for the range of configurations for which their adequate accuracy has been demonstrated.

(D) Acceptable comprehensive methods of analysis include: analytical, model tests, and chart methods which provide an evaluation of the forces, moments and stresses caused by bending and torsion from the simultaneous consideration of terminal and intermediate restraints to thermal expansion of the entire piping system under consideration, and including all external movements transmitted to the piping by its terminal and intermediate attachments. Correction factors shall be applied for the stress intensification of curved pipe and branch connections, as provided by the details of these rules, and may be applied for the increased flexibility of such component parts.

119.7.3 Basic Assumptions and Requirements. In calculating the flexibility of a piping system between anchor points, the system between anchor points shall be treated as a whole. The significance of all parts of the line and of all restraints, such as supports or guides, including intermediate restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, shall be considered.

Flexibility calculations shall take into account stress intensifying conditions found in components and joints. Credit may be taken when extra flexibility exists in such components. In the absence of more directly applicable data, the flexibility factors and stress-intensification factors shown in Appendix D may be used.[2]

Dimensional properties of pipe and fittings used in flexibility calculations shall be based on nominal dimensions.

The total expansion range as determined from para. 119.6.1 shall be used in all calculations, whether or not the piping is cold sprung. Not only the expansion of the line itself, but also linear and angular movements of the equipment to which it is attached shall be considered.

Where simplifying assumptions are used in calculations or model tests, the likelihood of attendant underestimates of forces, moments, and stresses, including the effects of stress-intensification shall be evaluated.

119.8 Movements

Movements caused by thermal expansion and loadings shall be determined for consideration of obstructions and design of proper supports.

119.9 Cold Spring

The beneficial effect of judicious cold springing in assisting a system to attain its most favorable position sooner is recognized. Inasmuch as the life of a system under cyclic conditions depends on the stress range rather than the stress level at any one time, no credit for cold spring is allowed with regard to stresses. In

[2] The stress-intensification factors in Appendix D have been developed from fatigue tests of representative commercially available, matching product forms and assemblies manufactured from ductile ferrous materials. The allowable stress-range is based on tests of carbon and stainless steels. Caution should be exercised when applying Figs. (1) and (13) for the allowable stress-range for certain nonferrous materials (e.g., copper and aluminum alloys) for other than low cycle applications.

calculating end thrusts and moments acting on equipment, the actual reactions at any one time, rather than their range, are significant. Credit for cold springing is accordingly allowed in the calculation of thrusts and moments, provided an effective method of obtaining the designed cold spring is specified and used.

119.10 Reactions

01 **119.10.1 Computing Hot and Cold Reactions.** In a piping system with no cold spring or an equal percentage of cold springing in all directions, the reactions (forces and moments) of R_h and R_c, in the hot and cold conditions, respectively, shall be obtained from the reaction R derived from the flexibility calculations based on the modulus of elasticity at room temperature E_c, using Eqs. (9) and (10).

$$R_h = \left(1 - \tfrac{2}{3}C\right)\left(\frac{E_h}{E_c}R\right) \tag{9}$$

$$R_c = -CR, \text{ or}$$

$$= -\left[1 - \frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)}\right]R \tag{10}$$

whichever is greater, and with the further condition that

$$\frac{(S_h)}{(S_E)} \cdot \frac{(E_c)}{(E_h)} < 1$$

where

C = cold spring factor varying from zero for no cold spring to 1.00 for 100% cold spring

S_E = computed thermal expansion stress range, psi (MPa)

E_c = modulus of elasticity in the cold condition, psi (MPa)

E_h = modulus of elasticity in the hot condition, psi (MPa)

R = maximum reaction for full expansion range based on $E_c$which assumes the most severe condition (100% cold spring, whether such is used or not), lb and in-lb (N and mm-N)

R_c, R_h = maximum reactions estimated to occur in the cold and hot conditions, respectively, lb and in.-lb (N and mm-N)

If a piping system is designed with different percentages of cold spring in various directions, Eqs. (9) and (10) are not applicable. In this case, the piping system shall be analyzed by a comprehensive method. The calculated hot reactions shall be based on theoretical cold springs in all directions not greater than two-thirds of the cold springs as specified or measured.

119.10.2 Reaction Limits. The reactions computed shall not exceed limits which the attached equipment can sustain. Equipment allowable reaction limits (forces and moments) on piping connections are normally established by the equipment manufacturer.

120 LOADS ON PIPE SUPPORTING ELEMENTS

120.1 General

(A) The broad terms "Supporting Elements" or "Supports" as used herein shall encompass the entire range of the various methods of carrying the weight of pipe lines, insulation, and the fluid carried. It therefore includes "hangers" which are generally considered as those elements which carry the weight from above, with the supporting members being mainly in tension. Likewise, it includes "supports" which on occasion are delineated as those which carry the weight from below, with the supporting members being mainly in compression. In many cases a supporting element may be a combination of both of these.

(B) In addition to the weight effects of piping components, consideration shall be given in the design of pipe supports to other load effects introduced by service pressure, wind, earthquake, etc., as defined in para. 101. Hangers and supporting elements shall be fabricated and assembled to permit the free movement of piping caused by thermal expansion and contraction. The design of elements for supporting or restraining piping systems, or components thereof, shall be based on all the concurrently acting loads transmitted into the supporting elements.

(C) Where the resonance with imposed vibration and/or shock occurs during operation, suitable dampeners, restraints, anchors, etc., shall be added to remove these effects.

120.2 Supports, Anchors, and Guides

120.2.1 Rigid Type Supports

(A) The required strength of all supporting elements shall be based on the loadings as given in para. 120.1, including the weight of the fluid transported or the fluid used for testing, whichever is heavier. The allow-

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:20 2005

able stress in supporting equipment shall be as specified in para. 121.2.

(B) Exceptions may be made in the case of supporting elements for large size gas or air piping, exhaust steam, relief or safety valve relief piping, but only under the conditions where the possibility of the line becoming full of water or other liquid is very remote.

120.2.2 Variable and Constant Supports. Load calculations for variable and constant supports, such as springs or counterweights, shall be based on the design operating conditions of the piping. They shall not include the weight of the hydrostatic test fluid. However, the support shall be capable of carrying the total load under test conditions, unless additional support is provided during the test period.

120.2.3 Anchors or Guides. Where anchors or guides are provided to restrain, direct, or absorb piping movements, their design shall take into account the forces and moments at these elements caused by internal pressure and thermal expansion.

120.2.4 Supplementary Steel. Where it is necessary to frame structural members between existing steel members, such supplementary steel shall be designed in accordance with American Institute of Steel Construction specifications, the Uniform Building Code, or similar recognized structural design standards. Increases of allowable stress values for short duration loading, such as outlined in para. 121.2(I), are not permitted.

121 DESIGN OF PIPE SUPPORTING ELEMENTS

121.1 General

Design of standard pipe supporting elements shall be in accordance with the rules of MSS SP-58. Allowable stress values and other design criteria shall be in accordance with this paragraph. Supporting elements shall be capable of carrying the sum of all concurrently acting loads as listed in para. 120. They shall be designed to provide the required supporting effort and allow pipeline movement with thermal changes without causing overstress. The design shall also prevent complete release of the piping load in the event of spring failure or misalignment. All parts of the supporting equipment shall be fabricated and assembled so that they will not be disengaged by movement of the supported piping. The maximum safe loads for bolts, threaded hanger rods, and all other threaded members shall be based on the root area of the threads.

121.2 Allowable Stress Values 01

(A) Allowable stress values tabulated in MSS SP-58 or in Appendix A of this Code Section may be used for the base materials of all parts of pipe supporting elements.

(B) Where allowable stress values for a material specification listed in Table 126.1 are not tabulated in Appendix A or in MSS SP-58, allowable stress values from Section II, Part D, Tables 1A and 1B of the ASME Boiler and Pressure Vessel Code may be used, provided the requirements of para. 102.3.1(B) are met. Where there are no stress values given in Section II, Part D, Tables 1A and 1B, an allowable stress value of 25% of the minimum tensile strength given in the material specification may be used, for temperatures not exceeding 650°F (345°C).

(C) For a steel material of unknown specification, or of a specification not listed in Table 126.1 or MSS SP-58, an allowable stress value of 30% of yield strength (0.2% offset) at room temperature may be used at temperatures not exceeding 650°F (345°C). The yield strength shall be determined through a tensile test of a specimen of the material and shall be the value corresponding to 0.2% permanent strain (offset) of the specimen. The allowable stress values for such materials shall not exceed 9500 psi (65.5 MPa).

(D) The allowable shear stress shall not exceed 80% of the values determined in accordance with the rules of (A), (B), and (C) above.

(E) The allowable compressive stress shall not exceed the value as determined in accordance with the rules of (A), (B), or (C) above. In addition, consideration shall be given to structural stability.

(F) The allowable bearing stress shall not exceed 160% of the value as determined in accordance with the rules of (A), (B), or (C) above.

(G) The allowable base material tensile stress determined from (A), (B), or (C) above shall be reduced 25% for threaded hanger rods.

(H) The allowable stress in welds in support assemblies shall be reduced 25% from those determined in accordance with (A), (B), (C), or (D) above for the weaker of the two metals joined.

(I) Increases in the allowable stress values shall be permitted as follows:

(1) an increase of 20% for short time overloading during operation;

(2) an increase to 80% of the minimum yield strength at room temperature during hydrostatic testing. Where the material allowable stress has been established in accordance with the rules of (C) above, the allowable

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:20 2005

stress value during hydrostatic testing shall not exceed 16,000 psi (110.3 MPa).

121.3 Temperature Limitations

Parts of supporting elements which are subjected principally to bending or tension loads and which are subjected to working temperatures for which carbon steel is not recommended shall be made of suitable alloy steel, or shall be protected so that the temperature of the supporting member will be maintained within the appropriate temperature limits of the material.

121.4 Hanger Adjustments

Hangers used for the support of piping, NPS 2½ and larger, shall be designed to permit adjustment after erection while supporting the load. Screwed adjustments shall have threaded parts to conform to ASME B1.1.

Class 2 fit turnbuckles and adjusting nuts shall have the full length of thread in engagement. Means shall be provided for determining that full thread length is in engagement. All screw and equivalent adjustments shall be provided with suitable locking devices.

121.5 Hanger Spacing

Supports for piping with the longitudinal axis in approximately a horizontal position shall be spaced to prevent excessive sag, bending and shear stresses in the piping, with special consideration given where components, such as flanges and valves, impose concentrated loads. Where calculations are not made, suggested maximum spacing of supports for standard and heavier pipe are given in Table 121.5. Vertical supports shall be spaced to prevent the pipe from being overstressed from the combination of all loading effects.

121.6 Springs

The springs used in variable or constant effort type supports shall be designed and manufactured in accordance with MSS SP-58.

121.7 Fixtures

121.7.1 Anchors and Guides

(A) Anchors, guides, pivots, and restraints shall be designed to secure the desired points of piping in relatively fixed positions. They shall permit the piping to expand and contract freely in directions away from the anchored or guided point and shall be structurally suitable to withstand the thrusts, moments, and other loads imposed.

TABLE 121.5
SUGGESTED PIPE SUPPORT SPACING

Nominal Pipe Size, NPS	Suggested Maximum Span			
	Water Service		Steam, Gas, or Air Service	
	ft	m	ft	m
1	7	2.1	9	2.7
2	10	3.0	13	4.0
3	12	3.7	15	4.6
4	14	4.3	17	5.2
6	17	5.2	21	6.4
8	19	5.8	24	7.3
12	23	7.0	30	9.1
16	27	8.2	35	10.7
20	30	9.1	39	11.9
24	32	9.8	42	12.8

GENERAL NOTES:

(a) Suggested maximum spacing between pipe supports for horizontal straight runs of standard and heavier pipe at maximum operating temperature of 750°F (400°C).

(b) Does not apply where span calculations are made or where there are concentrated loads between supports, such as flanges, valves, specialties, etc.

(c) The spacing is based on a fixed beam support with a bending stress not exceeding 2300 psi (15.86 MPa) and insulated pipe filled with water or the equivalent weight of steel pipe for steam, gas, or air service, and the pitch of the line is such that a sag of 0.1 in. (2.5 mm) between supports is permissible.

(B) Rolling or sliding supports shall permit free movement of the piping, or the piping shall be designed to include the imposed load and frictional resistance of these types of supports, and dimensions shall provide for the expected movement of the supported piping. Materials and lubricants used in sliding supports shall be suitable for the metal temperature at the point of sliding contact.

(C) Where corrugated or slip-type expansion joints, or flexible metal hose assemblies are used, anchors and guides shall be provided where necessary to direct the expansion into the joint or hose assembly. Such anchors shall be designed to withstand the force specified by the manufacturer for the design conditions at which the joint or hose assembly is to be used. If this force is otherwise unknown, it shall be taken as the sum of the product of the maximum internal area times the design pressure plus the force required to deflect the joint or hose assembly. Where expansion joints or flexible metal hose assemblies are subjected to a combination of longitudinal and transverse movements, both movements shall be considered in the design and application of the joint or hose assembly.

3 1/4	6.720	4 335	60,500	27 442
3 1/2	7.918	5 108	71,260	32 323
3 3/4	9.214	5 945	82,900	37 640
4	10.608	6 844	95,500	43 360
4 1/4	12.100	7 806	108,900	49 440
4 1/2	13.690	8 832	123,200	55 930
4 3/4	15.379	9 922	138,400	62 830
5	17.165	11 074	154,500	70 140

GENERAL NOTE: Tabulated loads are based on an allowable tensile stress of 12,000 psi (82.7 MPa) reduced by 25% using the root thread area as a base. [Refer to para. 121.2(A).]

Flexible metal hose assemblies, applied in accordance with para. 106.4, shall be supported in such a manner as to be free from any effects due to torsion and undue strain as recommended by the manufacturer.

121.7.2 Other Rigid Types

(A) Hanger Rods. Safe loads for threaded hanger rods shall be based on the root area of the threads and allowable stress of the material. In no case shall hanger rods less than 3/8 in. (9.5 mm) diameter be used for support of pipe NPS 2 and smaller, or less than 1/2 in. (12.5 mm) diameter rod for supporting pipe NPS 2 1/2 and larger. See Table 121.7.2(A) for carbon steel rods.

Pipe, straps, or bars of strength and effective area equal to the equivalent hanger rod may be used instead of hanger rods.

Hanger rods, straps, etc., shall be designed to permit the free movement of piping caused by thermal expansion and contraction.

(B) Welded link chain of 3/16 in. (5.0 mm) or larger diameter stock, or equivalent area, may be used for pipe hangers with a design stress of 9000 psi (62 MPa) maximum.

(C) Cast iron in accordance with ASTM A 48 may be used for bases, rollers, anchors, and parts of supports where the loading will be mainly compression. Cast iron parts shall not be used in tension.

(D) Malleable iron castings in accordance with ASTM A 47 may be used for pipe clamps, beam clamps, hanger flanges, clips, bases, swivel rings, and parts of pipe supports, but their use shall be limited to temperatures not in excess of 450°F (230°C). This material is

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:21 2005

not recommended for services where impact loads are anticipated.

(E) Brackets shall be designed to withstand forces and moments induced by sliding friction in addition to other loads.

121.7.3 Variable Supports

(A) Variable spring supports shall be designed to exert a supporting force equal to the load, as determined by weight balance calculations, plus the weight of all hanger parts (such as clamp, rod, etc.) that will be supported by the spring at the point of attachment to the pipe.

(B) Variable spring supports shall be provided with means to limit misalignment, buckling, eccentric loading, or to prevent overstressing of the spring.

(C) It is recommended that all hangers employing springs be provided with means to indicate at all times the compression of the spring with respect to the approximate hot and cold positions of the piping system, except where they are used either to cushion against shock or where the operating temperature of the piping system does not exceed 250°F (120°C).

(D) It is recommended that the support be designed for a maximum variation in supporting effort of 25% for the total travel resulting from thermal movement.

121.7.4 Constant Supports. On high temperature and critical service piping at locations subject to appreciable movement with thermal changes, the use of constant support hangers, designed to provide a substantially uniform supporting force throughout the range of travel, is recommended.

(A) Constant support hangers shall have a support variation of no more than 6% throughout the total travel range.

(B) Counterweight type supports shall be provided with stops, and the weights shall be positively secured. Chains, cables, hanger and rocker arm details, or other devices used to attach the counterweight load to the piping, shall be subject to requirements of para. 121.7.2.

(C) Hydraulic type supports utilizing a hydraulic head may be installed to give a constant supporting effort. Safety devices and stops shall be provided to support the load in case of hydraulic failure.

(D) Boosters may be used to supplement the operation of constant support hangers.

121.7.5 Sway Braces. Sway braces or vibration dampeners shall be used to control the movement of piping due to vibration.

121.7.6 Shock Suppressors. For the control of piping due to dynamic loads, hydraulic or mechanical types of shock suppressors are permitted. These devices do not support pipe weight.

121.8 Structural Attachments

121.8.1 Nonintegral Type

(A) Nonintegral attachments include clamps, slings, cradles, saddles, straps, and clevises.

(B) When clamps are used to support vertical lines, it is recommended that shear lugs be welded to the pipe to prevent slippage. The provisions of para. 121.8.2(B) shall apply.

(C) In addition to the provision of (B) above, clamps to support vertical lines should be designed to support the total load on either arm in the event the load shifts due to pipe and/or hanger movement.

121.8.2 Integral Type

(A) Integral attachments include ears, shoes, lugs, cylindrical attachments, rings, and skirts which are fabricated so that the attachment is an integral part of the piping component. Integral attachments shall be used in conjunction with restraints or braces where multiaxial restraint in a single member is to be maintained. Consideration shall be given to the localized stresses induced into the piping component by the integral attachments. Where applicable, the conditions of para. 121.8.1(C) are to apply.

(B) Integral lugs, plates, angle clips, etc., used as part of an assembly for the support or guiding of pipe may be welded directly to the pipe provided the materials are compatible for welding and the design is adequate for the temperature and load. The design of hanger lugs for attachment to piping for high temperature service shall be such as to provide for differential expansion between the pipe and the attached lug.

Welds shall be proportioned so that the shear stresses do not exceed either 0.8 times the applicable S values for the pipe material shown in the Allowable Stress Tables, or the allowable stress values determined in accordance with para. 121.2(A), (B), or (C). If materials for attachments have different allowable stress values than the pipe, the lower allowable stress value of the two shall be used.

121.9 Loads and Supporting Structures

121.9.1 Considerations shall be given to the load carrying capacity of equipment and the supporting structure. This may necessitate closer spacing of hangers on lines with extremely high loads.

121.10 Requirements for Fabricating Pipe Supports

121.10.1 Pipe supports shall be fabricated in accordance with the requirements of para. 130.

PART 6
SYSTEMS

122 DESIGN REQUIREMENTS PERTAINING TO SPECIFIC PIPING SYSTEMS

Except as specifically stated otherwise in this Part 6, all provisions of the Code apply fully to the piping systems described herein.

122.1 Boiler External Piping; in Accordance With Para. 100.1.2(A) — Steam, Feedwater, Blowoff, and Drain Piping

122.1.1 General. The minimum pressure and temperature and other special requirements to be used in the design for steam, feedwater, blowoff, and drain piping from the boiler to the valve or valves required by para. 122.1 shall be as specified in the following paragraphs. Design requirements for desuperheater spray piping connected to desuperheaters located in the boiler proper are provided in para. 122.4.

(A) It is intended that the design pressure and temperature be selected sufficiently in excess of any expected operating conditions, not necessarily continuous, to permit satisfactory operation without operation of the overpressure protection devices. Also, since the operating temperatures of fired equipment can vary, the expected temperature at the connection to the fired equipment shall include the manufacturer's maximum temperature tolerance.

(B) In a forced flow steam generator with no fixed steam and waterline, it is permissible to design the external piping, valves, and fittings attached to the pressure parts for different pressure levels along the path through the steam generator of water-steam flow. The values of design pressure and the design temperature to be used for the external piping, valves, and fittings shall be not less than that required for the expected maximum sustained operating pressure and temperature to which the abutted pressure part is subjected except when one or more of the overpressure protection devices covered by PG-67.4 of Section I of the ASME Boiler and Pressure Vessel Code is in operation. The steam piping shall comply with the requirements for the maximum sustained operating conditions as used in (A) above, or for the design throttle pressure plus 5%, whichever is greater.

(C) Provision shall be made for the expansion and contraction of piping connected to boilers to limit forces and moments transmitted to the boiler, by providing substantial anchorage at suitable points, so that there shall be no undue strain transmitted to the boiler. Steam reservoirs shall be used on steam mains when heavy pulsations of the steam currents cause vibration.

(D) Piping connected to the outlet of a boiler for any purpose shall be attached by:

(D.1) welding to a nozzle or socket welding fitting;

(D.2) threading into a tapped opening with a threaded fitting or valve at the other end;

(D.3) screwing each end into tapered flanges, fittings, or valves with or without rolling or peening;

(D.4) bolted joints including those of the Van Stone type;

(D.5) blowoff piping of firetube boilers shall be attached in accordance with (D.2) above if exposed to products of combustion or in accordance with (D.2), (D.3), or (D.4) above if not so exposed.

(E) Nonferrous pipe or tubes shall not exceed NPS 3 in diameter.

(F) American National Standard slip-on flanges shall not exceed NPS 4. Attachment of slip-on flanges shall be by double fillet welds. The throats of the fillet welds shall not be less than 0.7 times the thickness of the part to which the flange is attached.

(G) Hub-type flanges shall not be cut from plate material.

(H) American National Standard socket welded flanges may be used in piping or boiler nozzles provided the dimensions do not exceed NPS 3 for Class 600 and lower and NPS $2\frac{1}{2}$ in Class 1500.

122.1.2 Steam Piping

(A) The value of P to be used in the formulas in para. 104 shall be as follows.

(A.1) For steam piping connected to the steam drum or to the superheater inlet header up to the first stop valve in each connection, the value of P shall be not less than the lowest pressure at which any drum safety valve is set to blow, and the S value shall not exceed that permitted for the corresponding saturated steam temperature.

(A.2) For steam piping connected to the superheater outlet header up to the first stop valve in each connection, the design pressure, except as otherwise provided in (A.4) below shall be not less than the lowest pressure at which any safety valve on the superheater is set to blow, or not less than 85% of the lowest pressure at

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:22 2005

which any drum safety valve is set to blow, whichever is greater, and the S value for the material used shall not exceed that permitted for the expected steam temperature.

(A.3) For steam piping between the first stop valve and the second valve, when one is required by para. 122.1.7, the design pressure shall be not less than the expected maximum sustained operating pressure or 85% of the lowest pressure at which any drum safety valve is set to blow, whichever is greater, and the S value for the material used shall not exceed that permitted for the expected steam temperature.

(A.4) For boilers installed on the unit system (i.e., one boiler and one turbine or other prime mover) and provided with automatic combustion control equipment responsive to steam header pressure, the design pressure for the steam piping shall be not less than the design pressure at the throttle inlet plus 5%, or not less than 85% of the lowest pressure at which any drum safety valve is set to blow, or not less than the expected maximum sustained operating pressure at any point in the piping system, whichever is greater, and the S value for the material used shall not exceed that permitted for the expected steam temperature at the superheater outlet. For forced-flow steam generators with no fixed steam and waterline, the design pressure shall also be no less than the expected maximum sustained operating pressure.

(A.5) The design pressure shall not be taken at less than 100 psig [700 kPa (gage)] for any condition of service or material.

122.1.3 Feedwater Piping

(A) The value of P to be used in the formulas in para. 104 shall be as follows.

(A.1) For piping from the boiler to and including the required stop valve and the check valve, the minimum value of P except as permitted in para. 122.1.3(A.4) shall exceed the maximum allowable working pressure of the boiler by either 25% or 225 psi (1550 kPa), whichever is the lesser. For an installation with an integral economizer without valves between the boiler and economizer, this paragraph shall apply only to the piping from the economizer inlet header to and including the required stop valve and the check valve.

(A.2) For piping between the required check valve and the globe or regulating valve, when required by para. 122.1.7(B), and including any bypass piping up to the shutoff valves in the bypass, the value of P shall be not less than the pressure required to feed the boiler.

(A.3) The value of P in the formula shall not be taken at less than 100 psig [700 kPa (gage)] for any condition of service or material, and shall never be less than the pressure required to feed the boiler.

(A.4) In a forced flow steam generator with no fixed steam and waterline, the value of P for feedwater piping from the boiler to and including the required stop valve may be in accordance with the requirements of para. 122.1.1(B).

(B) The S value used, except as permitted in (A.4) above, shall not exceed that permitted for the temperature of saturated steam at the maximum allowable working pressure of the boiler.

(C) The size of the feed piping between the boiler and the first required valve [para. 122.1.7(B)] or the branch feed connection [para. 122.1.7(B.4)] shall, as a minimum, be the same as the boiler connection.

122.1.4 Blowoff and Blowdown Piping. Blowoff and blowdown piping are defined as piping connected to a boiler and provided with valves or cocks through which the water in the boiler may be blown out under pressure. This definition is not intended to apply to (i) drain piping, and (ii) piping such as used on water columns, gage glasses, or feedwater regulators, etc., for the purpose of determining the operating condition of the equipment. Requirements for (i) and (ii) are described in paras. 122.1.5 and 122.1.6. Blowoff systems are operated intermittently to remove accumulated sediment from equipment and/or piping, or to lower boiler water level in a rapid manner. Blowdown systems are primarily operated continuously to control the concentrations of dissolved solids in the boiler water.

(A) Blowoff piping systems from water spaces of a boiler, up to and including the blowoff valves, shall be designed in accordance with (A.1) to (A.4) below. Two shutoff valves are required in the blowoff system; specific valve requirements and exceptions are given in para. 122.1.7(C).

(A.1) The value of P to be used in the formulas in para. 104 shall exceed the maximum allowable working pressure of the boiler by either 25% or 225 psi (1550 kPa) whichever is less, but shall not be less than 100 psig [700 kPa (gage)].

(A.2) The allowable stress value for the piping materials shall not exceed that permitted for the temperature of saturated steam at the maximum allowable working pressure of the boiler.

(A.3) All pipe shall be steel. Galvanized steel pipe and fittings shall not be used for blowoff piping. When the value of P does not exceed 100 psig [700 kPa (gage)], the fittings shall be bronze, cast iron, malleable

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:22 2005

iron, ductile iron, or steel. When the value of P exceeds 100 psig [700 kPa (gage)], the fittings shall be steel and the thickness of pipe and fittings shall not be less than that of Schedule 80 pipe.

(A.4) The size of blowoff piping shall be not less than the size of the connection on the boiler, and shall be in accordance with the rules contained in the ASME Boiler and Pressure Vessel Code, Section I, PG-59.3 and PEB-12.

(B) The blowdown piping system from the boiler, to and including the shutoff valve, shall be designed in accordance with (B.1) through (B.4) below. Only one shutoff valve is required in the blowdown system.

(B.1) The value of P to be used in the formulas in para. 104 shall be not less than the lowest set pressure of any safety valve on the boiler drum.

(B.2) The allowable stress value for the piping materials shall not exceed that permitted for the temperature of saturated steam at the maximum allowable working pressure of the boiler.

(B.3) All pipe shall be steel. Galvanized steel pipe and fittings shall not be used for blowdown piping. When the value of P does not exceed 100 psig [700 kPa (gage)], the fittings shall be bronze, cast iron, malleable iron, ductile iron, or steel. When the value of P exceeds 100 psig [700 kPa (gage)], the fittings shall be steel and the thickness of pipe and fittings shall not be less than that of Schedule 80 pipe.

(B.4) The size of blowdown piping shall be not less than the size of the connection on the boiler, and shall be in accordance with the rules contained in the ASME Boiler and Pressure Vessel Code, Section I, PG-59.3.

(C) The blowoff and blowdown piping beyond the required valves described in (A) and (B) above are classified as nonboiler external piping. The requirements are given in para. 122.2.

122.1.5 Boiler Drains

(A) Complete drainage of the boiler and attached piping shall be provided to the extent necessary to ensure proper operation of the steam supply system. The pipe, fittings, and valves of any drain line shall not be smaller than the drain connection.

(B) If the drain lines are intended to be used both as drains and as blowoffs, then two valves are required and all conditions of paras. 122.1.4, 122.1.7(C), and 122.2 shall be met.

(C) When a drain is intended for use only when the boiler is not under pressure (pressurizing the boiler for rapid drainage is an exception), a single shutoff valve is acceptable under the following conditions: either the valve shall be a type that can be locked in the closed position or a suitable flanged and bolted connection that accepts a blank insert shall be located on the downstream side of the valve. When a single valve is used, it need not be designed for blowoff service.

(D) Drain piping from the drain connection, including the required valve(s) or the blanked flange connection, shall be designed for the temperature and pressure of the drain connection. The remaining piping shall be designed for the expected maximum temperature and pressure. Static head and possible choked flow conditions shall be considered. In no case shall the design pressure and temperature be less than 100 psig [700 kPa (gage)] and 220°F (104°C), respectively.

122.1.6 Boiler External Piping — Miscellaneous Systems

(A) Materials, design, fabrication, examination, and erection of piping for miscellaneous accessories, such as water level indicators, water columns, gage cocks, and pressure gages, shall be in accordance with the applicable sections of this Code.

(B) The value of P to be used in the Formulas in para. 104 shall be not less than the maximum allowable working pressure of the boiler except as provided by para. 122.1.1(B).

(C) Valve requirements for water level indicators or water columns, special gage glass and gage cock requirements, minimum line sizes, and special piping configurations required specifically for cleaning, access, or reliability shall be in accordance with PG-60 of Section I of the ASME Boiler and Pressure Vessel Code.

122.1.7 Valves and Fittings. The minimum pressure and temperature rating for all valves and fittings in steam, feedwater, blowoff, and miscellaneous piping shall be equal to the pressure and temperature specified for the connected piping on the side that has the higher pressure, except that in no case shall the pressure be less than 100 psig [700 kPa (gage)], and for pressures not exceeding 100 psig [700 kPa (gage)] in feedwater and blowoff service, the valves and fittings shall be equal at least to the requirements of the ASME standards for Class 125 cast iron or Class 150 steel.

(A) Steam Stop Valves. Each boiler discharge outlet, except safety valve or safety relief valve connections, or reheater inlet and outlet connections, shall be fitted with a stop valve located at an accessible point in the steam-delivery line and as near to the boiler nozzle as is convenient and practicable.

(A.1) Boiler stop valves shall provide bidirectional shutoff at design conditions. The valve or valves shall meet the requirements of para. 107. Valves with resilient

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:23 2005

(nonmetallic) seats shall not be used where the boiler maximum allowable working pressure exceeds 1035 kPa (150 psig) or where the system design temperature exceeds 186°C (366°F). Valves of the outside screw and yoke, rising stem style are preferred. Valves other than those of the outside screw and yoke, rising stem style shall meet the following additional requirements.

(A.1.A) Each valve shall be equipped with a position indicator to visually indicate from a distance whether the valve is open or closed.

(A.1.B) Quarter turn valves shall be equipped with a slow operating mechanism to minimize dynamic loadings on the boiler and attached piping.

(A.2) In the case of a single boiler and prime mover installation, the stop valve required herein may be omitted provided the prime mover throttle valve is equipped with an indicator to show whether it is opened or closed, and it is designed to withstand the required boiler hydrostatic test.

01 *(A.3)* When two or more boilers are connected to a common header, or when a single boiler is connected to a header having another steam source, the connection from each boiler having a man-hole opening shall be fitted with two stop valves having an ample free-blow drain between them. The preferred arrangement consists of one stop-check valve (located closest to the boiler) and one valve of the style and design described in (A.1) above. Alternatively, both valves may be of the style and design described in (A.1) above.

When a second stop valve is required, it shall have a pressure rating at least equal to that required for the expected steam pressure and temperature at the valve, or a pressure rating at least equal to 85% of the lowest set pressure of any safety valve on the boiler drum at the expected temperature of the steam at the valve, whichever is greater.

(A.4) All valves and fittings on steam lines shall have a pressure rating of at least 100 psig [700 kPa (gage)] in accordance with the applicable ASME Standard.

(B) Feedwater Valves

(B.1) The feedwater piping for all boilers, except for high temperature water boilers complying with the requirements of (B.8) below, and for forced flow steam generators with no fixed steam and water line complying with the requirements of (B.9) below, shall be provided with a check valve and a stop valve or cock between the check valve and the boiler. The stop valve or cock shall comply with the requirements of (C.5) below.

(B.2) The relative locations of the check and stop (or cock) valves, as required in (B.1) above, may be reversed on a single boiler-turbine unit installation.

(B.3) If a boiler is equipped with a duplicate feed arrangement, each such arrangement shall be equipped as required by these rules.

(B.4) When the supply line to a boiler is divided into branch feed connections and all such connections are equipped with stop and check valves, the stop and check valves in the common source may be omitted.

(B.5) When two or more boilers are fed from a common source, there shall also be a globe or regulating valve in the branch to each boiler located between the check valve and the source of supply. A typical arrangement is shown in Fig. 100.1.2(B). Wherever globe style valves are used on feed piping, the inlet shall be under the disk of the valve.

(B.6) A combination stop and check valve in which there is only one seat and disk, and in which a valve stem is provided to close the valve, shall be considered only as a stop valve, and a check valve shall be installed as otherwise provided.

(B.7) Where an economizer or other feedwater heating device is connected directly to the boiler without intervening valves, the feed valves and check valves required shall be placed on the inlet of the economizer or feedwater heating device.

(B.8) The recirculating return line for a high temperature water boiler shall be provided with the same stop valve, or valves, required by (B.1) and (B.3) above. The use of a check valve in the recirculating return line is optional. A check valve shall not be a substitute for a stop valve.

(B.9) The feedwater boiler external piping for a forced flow steam generator with no fixed steam and water line may terminate up to and including the stop valve(s) and omitting the check valve(s) provided that a check valve having a pressure rating no less than the boiler inlet design pressure is installed at the discharge of each boiler feed pump or elsewhere in the feedline between the feed pump and the stop valve(s).

(C) Blowoff Valves

(C.1) Ordinary globe valves as shown in Fig. 122.1.7(C) sketch (1), and other types of valves that have dams or pockets where sediment can collect, shall not be used on blowoff connections.

(C.2) Y-type globe valves as shown in Fig. 122.1.7(C) sketch (2) or angle valves may be used in vertical pipes, or they may be used in horizontal runs of piping provided they are so constructed or installed that the lowest edge of the opening through the seat is at least 25% of the inside diameter below the center line of the valve.

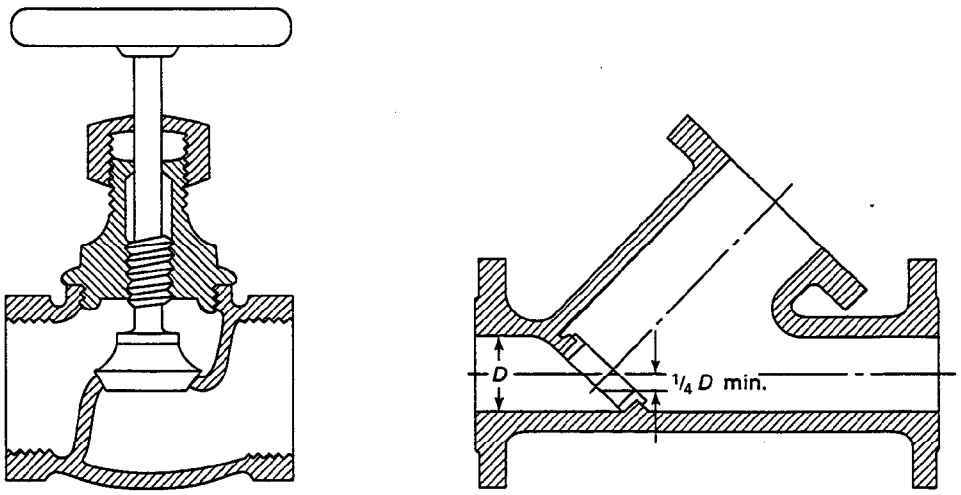

FIG. 122.1.7(C) TYPICAL GLOBE VALVES

(C.3) The blowoff valve or valves, the pipe between them, and the boiler connection shall be of the same size except that a larger pipe for the return of condensate may be used.

(C.4) For all boilers [except electric steam boilers having a normal water content not exceeding 100 gal (380 l), traction-purpose, and portable steam boilers; see (C.11) and (C.12) below] with allowable working pressure in excess of 100 psig [700 kPa (gage)], each bottom blowoff pipe shall have two slow-opening valves, or one quick-opening valve or cock, at the boiler nozzle followed by a slow-opening valve. All valves shall comply with the requirements of (C.5) and (C.6) below.

(C.5) When the value of P required by para. 122.1.4(A.1) does not exceed 250 psig [1750 kPa (gage)], the valves or cocks shall be bronze, cast iron, ductile iron, or steel. The valves or cocks, if of cast iron, shall not exceed NPS $2\frac{1}{2}$ and shall meet the requirements of the applicable ASME Standard for Class 250, as given in Table 126.1, and if of bronze, steel, or ductile iron construction, shall meet the requirements of the applicable standards as given in Table 126.1 or para. 124.6.

(C.6) When the value of P required by para. 122.1.4(A.1) is higher than 250 psig [1750 kPa (gage)], the valves or cocks shall be of steel construction equal at least to the requirements of Class 300 of the applicable ASME Standard listed in Table 126.1. The minimum pressure rating shall be equal to the value of P required by para. 122.1.4(A.1).

(C.7) If a blowoff cock is used, the plug shall be held in place by a guard or gland. The plug shall be distinctly marked in line with the passage.

(C.8) A slow-opening valve is a valve which requires at least five 360 deg turns of the operating mechanism to change from fully closed to fully opened.

(C.9) On a boiler having multiple blowoff pipes, a single master valve may be placed on the common blowoff pipe from the boiler, in which case only one valve on each individual blowoff is required. In such a case, either the master valve or the individual valves or cocks shall be of the slow-opening type.

(C.10) Two independent slow-opening valves, or a slow-opening valve and a quick-opening valve or cock, may be combined in one body and may be used provided the combined fitting is the equivalent of two independent slow-opening valves, or a slow-opening valve and a quick-opening valve or cock, and provided further that the failure of one to operate cannot affect the operation of the other.

(C.11) Only one blowoff valve, which shall be either a slow-opening or quick-opening blowoff valve or a cock, is required on traction and/or portable boilers.

(C.12) Only one blowoff valve, which shall be of a slow-opening type, is required on forced circulation and electric steam boilers having a normal water content not exceeding 100 gal (380 liter).

(D) Safety Valves

(D.1) Safety valves, relief valves, and safety relief valves shall conform to the requirements of PG-67,

TABLE 122.2

Boiler or Vessel Pressure		Design Pressure		Design Temperature	
psig	kPa (gage)	psig	kPa (gage)	°F	°C
Below 250	1 750	Note (1)		...	...
250–600	1 750–4 150	250	1750	410	210
601–900	4 151–6 200	400	2750	450	230
901–1500	6 201–10 300	600	4150	490	255
1501 and higher	10 301 and higher	900	6200	535	280

NOTE:
(1) For boiler or vessel pressure(s) below 250 psig [1750 kPa (gage)], the design pressure shall be determined in accordance with para. 122.1.4(B.1) but need not exceed 250 psig [1750 kPa (gage)].

PG-68, PG-69, PG-70, PG-71, PG-72, and PG-73 of Section I of the ASME Boiler and Pressure Vessel Code.

122.2 Blowoff and Blowdown Piping in Nonboiler External Piping

(A) From Boilers

(A.1) Blowoff piping, located between the valves described in para. 122.1.4(A) and the blowoff tank or other point where the pressure is reduced approximately to atmospheric pressure and cannot be increased by closing a valve, shall be designed for saturated steam at the appropriate pressure and temperature in accordance with Table 122.2. The provisions of para. 122.1.4(A.3) shall apply.

(A.2) Blowdown piping, located after the valve described in para. 122.1.4(B) in which the pressure cannot be increased by closing a valve, shall be designed for the appropriate pressure and temperature in accordance with Table 122.2. The provisions of para. 122.1.4(B.3) shall apply.

(A.3) When design pressure of Table 122.2 can be exceeded due either to closing of a downstream valve, calculated pressure drop, or other means, the entire blowoff or blowdown piping system shall be designed in accordance with para. 122.1.4(A) or (B), respectively.

(B) From Pressure Vessels Other Than Boilers

(B.1) The design pressure and temperature of the blowoff piping from the pressure vessel to and including the blowoff valve(s) shall not be less than the vessel design conditions.

122.3 Instrument, Control, and Sampling Piping

(A) The requirements of this Code, as supplemented by para. 122.3, shall apply to the design of instrument, control, and sampling piping for safe and proper operation of the piping itself.

(B) The term "Instrument Piping" shall apply to all valves, fittings, tubing, and piping used to connect instruments to main piping or to other instruments or apparatus or to measuring equipment as used within the classification of para. 100.1.

(C) The term "Control Piping" shall apply to all valves, fittings, tubing, and piping used to interconnect pneumatically or hydraulically operated control apparatus, also classified in accordance with para. 100.1, as well as to signal transmission systems used to interconnect instrument transmitters and receivers.

(D) The term "Sampling Piping" shall apply to all valves, fittings, tubing, and piping used for the collection of samples, such as steam, water, oil, gas, and chemicals.

(E) Paragraph 122.3 does not apply to tubing used in permanently closed systems, such as fluid-filled temperature responsive devices, or the temperature responsive devices themselves.

(F) Paragraph 122.3 does not apply to the devices, apparatus, measuring, sampling, signalling, transmitting, controlling, receiving, or collecting instruments to which the piping is connected.

122.3.1 Materials and Design. The materials utilized for valves, fittings, tubing, and piping shall meet the particular conditions of service and the requirements of the applicable specifications listed under general paras. 105, 106, 107, and 108 with allowable stresses in accordance with the Allowable Stress Tables in Appendix A.

The materials for pressure retention components used for piping specialities such as meters, traps, and strainers in flammable, combustible, or toxic fluid systems shall in addition conform to the requirements of paras. 122.7 and 122.8.

122.3.2 Instrument Piping

(A) Takeoff Connections

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:24 2005

(A.1) Takeoff connections at the source, together with attachment bosses, nozzles, and adapters, shall be made of material at least equivalent to that of the pipe or vessel to which they are attached. The connections shall be designed to withstand the source design pressure and temperature and be capable of withstanding loadings induced by relative displacement and vibration. The nominal size of the takeoff connections shall not be less than NPS $\frac{1}{2}$ for service conditions not in excess of either 900 psi (6200 kPa) or 800°F (425°C), and NPS $\frac{3}{4}$ (for adequate physical strength) for design conditions which exceed either of these limits. Where the size of the main is smaller than the limits given above, the takeoff connection shall not be less than the size of the main line.

(A.2) To prevent thermal shock to the main steam line by contact with the colder condensate return from the instrument, steam meter or instrument takeoff connections shall be lagged in with the steam main. For temperature in excess of 800°F (425°C), they may also be arranged to make metallic contact lengthwise with the steam main.

(B) Valves

(B.1) Shutoff Valves. Shutoff valves shall be provided at takeoff connections. They shall be capable of withstanding the design pressure and temperature of the pipe or vessel to which the takeoff adapters or nipples are attached.

(B.2) Blowdown Valves

(B.2.1) Blowdown valves at or near the instrument shall be of the gradual opening type. For subcritical pressure steam service, the design pressure for blowdown valves shall be not less than the design pressure of the pipe or vessel; the design temperature shall be the corresponding temperature of saturated steam. For all other services, blowdown valves shall meet the requirements of (B.1) above.

(B.2.2) When blowdown valves are used, the valves at the instrument as well as any intervening fittings and tubing between such blowdown valves and the meter shall be suitable at 100°F (40°C) for at least $1\frac{1}{2}$ times the design pressure of the piping system, but the rating of the valve at the instrument need not exceed the rating of the blowdown valve.

(B.2.3) When blowdown valves are not used, instrument valves shall conform to the requirements of (B.2.1) above.

(C) Reservoirs or Condensers. In dead end steam service, the condensing reservoirs and connecting nipples, which immediately follow the shutoff valves, shall be made of material suitable for the saturated steam temperature corresponding to the main line design pressure.

(D) Materials for Lines Between Shutoff Valves and Instruments

(D.1) Copper, copper alloys, and other nonferrous materials may be used in dead end steam or water services up to the design pressure and temperature conditions used for calculating the wall thickness in accordance with para. 104 provided that the temperature within the connecting lines for continuous services does not exceed 406°F (208°C).

Where water temperature in the reservoir of condensers is above 406°F (208°C), a length of uninsulated steel tubing at least 5 ft (1.5 m) long shall immediately follow the condenser ahead of the connecting copper tubing to the instrument.

(D.2) The minimum size of the tubing or piping is a function of its length, the volume of fluid required to produce full scale deflections of the instrument, and the service of the instrument. When required to prevent plugging as well as to obtain sufficient mechanical strength, the inside diameter of the pipe or tube should not be less than 0.36 in. (9.14 mm), with a wall thickness of not less than 0.049 in. (1.25 mm). When these requirements do not apply, smaller sizes with wall thickness in due proportions may be used. In either case, wall thickness of the pipe or tube shall meet the requirements of (D.3) below.

(D.3) The piping or tubing shall be designed in accordance with para. 104 with consideration for water hammer.

(E) Fittings and Joints

(E.1) For dead end steam service and for water above 150°F (65°C), fittings of the. flared, flareless, or socket welding type, or other suitable type of similar design shall be used. The fittings shall be suitable for the header pressure and corresponding saturated steam temperature or water temperature, whichever applies. For supercritical pressure conditions the fittings shall be suitable for the design pressure and temperature of the main fluid line.

(E.2) For water, oil and similar instrument services, any of the following types may be used, within the pressure-temperature limitations of each.

(E.2.1) For main line hydraulic pressures above 500 psi (3450 kPa) and temperatures up to 150°F (65°C), steel fittings either of the flared, flareless, socket welded, fusion welded, or silver brazed socket type shall be used.

(E.2.2) For main line pressures up to 500 psi (3450 kPa) and temperatures up to 150°F (65°C), the fittings may be: (E.2.2.1) flared or silver brazed socket type,

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:24 2005

inverted flared or flareless compression type, all of brass or bronze.

(E.2.3) For pressures up to 175 psi (1200 kPa) or temperatures up to 250°F (120°C), soldered type fittings may be used with water-filled or air-filled tubing under adjusted pressure-temperature ratings. These fittings are not recommended where mechanical vibration, hydraulic shock, or thermal shock are encountered.

122.3.3 Control Piping

(A) Takeoff Connections

(A.1) Takeoff connections shall be in accordance with para. 122.3.2(A.1).

(B) Valves

(B.1) Shutoff valves shall be in accordance with para. 122.3.2(B.1).

(C) Materials

(C.1) The same materials may be used for control lines as for instrument lines, except that the minimum inside diameter shall be 0.178 in. (4.52 mm) with a minimum wall thickness of 0.028 in. (0.71 mm), provided that this wall thickness is not less than that required by para. 122.3.2(D.3). If a control device has a connection smaller than $\frac{1}{4}$ in. (6.0 mm), the size reduction from the control tubing to the control device shall be made as close to the control device as possible.

(D) Fittings and Joints

(D.1) Fittings and joints shall be in accordance with para. 122.3.2(E.2).

122.3.4 Sampling Piping

(A) Takeoff Connections

(A.1) Takeoff connections shall be in accordance with para. 122.3.2(A.1).

(B) Valves

(B.1) Shutoff valves shall be in accordance with para. 122.3.2(B.1).

(B.2) Blowdown valves shall be of the gradual opening type and shall be suitable for main line design pressure and temperature.

(C) Materials

(C.1) The materials to be used for sampling lines shall conform to minimum requirements for the main line to which they connect.

(D) Fittings and Joints

(D.1) For subcritical and supercritical pressure steam, and for water above 150°F (65°C), fittings of the flared, flareless, or socket welding type, or other suitable type of similar design shall be used. The fittings shall be suitable for main line design pressure and temperature.

(D.2) For water below 150°F (65°C), fittings and joints shall be suitable for main line design pressure and temperature and shall be in accordance with para. 122.3.2(E.2).

122.3.6 Fittings and Joints

(A) All fittings shall be in accordance with standards and specifications listed in Table 126.1.

(A.1) Socket welded joints shall comply with the requirements of para. 111.3.

(A.2) Flared, flareless, and compression type fittings and their joints shall comply with the requirements of para. 115.

(A.3) Silver brazed socket type joints shall comply with the requirements of paras. 117.1 and 117.3.

(A.4) Solder type joints shall comply with the requirements of paras. 117.2 and 117.3.

(A.5) The use of taper threaded joints up to and including NPS $\frac{1}{2}$ is permitted at pressures up to 5000 psi (34 500 kPa) in dead end service from outlet end and downstream of shutoff valve located at instrument, at control apparatus, or at discharge of sample cooler.

122.3.7 Special Safety Provisions

(A) Connecting piping subject to clogging from solids or deposits shall be provided with suitable connections for cleaning.

(B) Connecting piping handling air and gases containing moisture or other extraneous materials shall be provided with suitable drains or settling chambers or traps.

(C) Connecting piping which may contain liquids shall be protected from damage due to freezing by heating or other adequate means.

122.3.8 Supports. Supports shall be furnished as specified in para. 121 not only for safety but also to protect the piping against detrimental sagging, external mechanical injury abuse, and exposure to unusual service conditions.

122.3.9 Installations

(A) Instrument, control, and sampling piping shall be inspected and tested in accordance with paras. 136 and 137.

(B) The inside of all piping, tubing, valves, and fittings shall be smooth, clean, and free from blisters, loose mill scale, sand, and dirt when erected. All lines shall be cleaned after installation and before placing in service.

122.4 Spray Type Desuperheater Piping for Use on Steam Generators and Reheat Piping 01

(A) Valves and Piping Arrangement

(A.1) Each spraywater pipe connected to a desuper-

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:25 2005

heater shall be provided with a stop valve and a regulating (spray control) valve. The regulating valve shall be installed upstream of the stop valve. In addition, if the steam generator supplies steam to a steam turbine, a power-operated block valve[3] shall be installed upstream of the regulating valve.

(A.2) A bypass valve around the regulating valve is permitted.

(A.3) A bypass valve around the power-operated block valve is prohibited.

(A.4) On a reheater desuperheater, a drain valve shall be installed between the power-operated block valve and the regulating valve.

(A.5) If the spraywater supply is from the boiler feedwater system and its source is not downstream of the feedwater check valve required by para. 122.1.7, a check valve shall be provided in the spraywater piping between the desuperheater and the spraywater source.

(A.6) It is recommended that the valves and piping be arranged to provide a head of water on the downstream side of the stop valve.

(A.7) A typical arrangement is shown in Fig. 122.4.

(A.8) Provisions shall be made to both steam and water systems to accommodate the operating conditions associated with this service including: water hammer, thermal shock and direct water impingement. The connection for the spraywater pipe should be located per the requirements established by the manufacturer so that complete flow mixing is achieved prior to any bends, elbows, or other flow directional changes being encountered.

(A.9) Insertable-type desuperheaters, which include an integral stop and spraywater regulating valve, may be used within the limitations established by the manufacturer. If this type is used, the individual stop and regulating valves shown in Fig. 122.4 may be omitted. All other requirements described in para. 122.4 shall apply.

(A.10) For Desuperheaters Located Within Reheat Piping. The steam system to be desuperheated shall be provided with proper drainage during all water flow conditions. The drainage system shall function both manually and automatically.

(B) Design Requirements

(B.1) The value of P to be used in the formulas of para. 104 shall be as follows.

(B.1.1) For piping from the desuperheater back to the stop valve required by (A.1) above, the value of P shall be equal to or greater than the maximum allowable working pressure of the desuperheater.

(B.1.2) For the remainder of the spraywater piping system, the value of P shall be not less than the maximum sustained pressure exerted by the spraywater.

(B.2) The stop valve required by (A.1) above shall be designed for the pressure requirement of (B.1.1) above or the maximum sustained pressure exerted by the spraywater, whichever is greater.

(B.3) The S value used for the spraywater piping shall not exceed that permitted for the expected temperature.

NOTE: The temperature varies from that of the desuperheater to that of the spraywater source and is highly dependent on the piping arrangement. It is the responsibility of the designer to determine the design temperature to be used for the various sections of the piping system.

122.5 Pressure Reducing Valves

122.5.1 General. Where pressure reducing valves are used, one or more relief devices or safety valves shall be provided on the low pressure side of the system. Otherwise, the piping and equipment on the low pressure side of the system shall be designed to withstand the upstream design pressure. The relief or safety devices shall be located adjoining or as close as practicable to the reducing valve. The combined relieving capacity provided shall be such that the design pressure of the low pressure system will not be exceeded if the reducing valve fails open.

122.5.2 Bypass Valves. Hand controlled bypass valves having a capacity no greater than the reducing valve may be installed around pressure reducing valves if the downstream piping is protected by relief valves as required in para. 122.5.1 or if the design pressure of the downstream piping system and equipment is at least as high as the upstream pressure.

122.5.3 Design of Valves and Relief Devices. Pressure reducing and bypass valves, and relief devices, shall be designed for inlet pressure and temperature conditions. Safety and relief valves shall be in accordance with the requirements of para. 107.8 of this Code.

122.6 Pressure Relief Piping

Pressure relief piping within the scope of this Code shall be supported to sustain reaction forces, and shall conform to the following requirements.

[3] For information on the prevention of water damage to steam turbines used for electric power generation, see ASME TDP-1.

GENERAL NOTE: This figure is a schematic only and is not intended to show equipment layout or orientation.

01 FIG. 122.4 DESUPERHEATER SCHEMATIC ARRANGEMENT

122.6.1 Piping to Pressure-Relieving Safety Devices

(A) There shall be no intervening stop valve(s) between piping being protected and the protective device(s).

(B) Diverter or changeover valves designed to allow servicing of redundant protective devices without system depressurization may be installed between the piping to be protected and the required protective devices under the following conditions.

(B.1) Diverter or changeover valves are prohibited on boiler external piping or reheat piping.

(B.2) One hundred percent (100%) of the required relieving capacity shall be continuously available any time the system is in service.

(B.3) Positive position indicators shall be provided on diverter or changeover valves.

(B.4) Positive locking mechanisms and seals shall be provided on diverter or changeover valves to preclude unauthorized or accidental operation.

(B.5) Diverter or changeover valves shall be designed for the most severe conditions of pressure, temperature, and loading to which they are exposed, and shall be in accordance with para. 107.

(B.6) Provision shall be made to safely bleed off the pressure between the isolated protective device and the diverter or changeover valve.

122.6.2 Discharge Piping From Pressure Relieving Safety Devices

(A) There shall be no intervening stop valve between the protective device or devices and the point of discharge.

(B) When discharging directly to the atmosphere, discharge shall not impinge on other piping or equipment and shall be directed away from platforms and other areas used by personnel.

(C) It is recommended that individual discharge lines be used, but if two or more reliefs are combined, the discharge piping shall be designed with sufficient flow area to prevent blowout of steam or other fluids. Sectional areas of a discharge pipe shall not be less than the full area of the valve outlets discharging thereinto and the discharge pipe shall be as short and straight as possible and so arranged as to avoid undue stresses on the valve or valves.

(D) Discharge lines from pressure-relieving safety devices within the scope of this Code shall be designed to facilitate drainage.

(E) When the umbrella or drip pan type of connection

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:26 2005

is used, the discharge piping shall be so designed as to prevent binding due to expansion movements.

(F) Drainage shall be provided to remove water collected above the safety valve seat.

(G) Carbon steel materials listed in Appendix A may be used for discharge piping which is subjected to temperatures above 800°F (427°C) only during operation of pressure relieving safety devices provided that:

(G.1) the duration of pressure relieving safety device operation is self-limiting;

(G.2) the piping discharges directly to atmosphere;

(G.3) material allowable stresses at temperatures above 800°F (427°C) shall be taken from Section II, Part D, Tables 1A and 1B for materials applicable to Section I and Section VIII, Division 1 of the ASME Boiler and Pressure Vessel Code.

122.7 Piping for Flammable or Combustible Liquids

122.7.1 General. Piping for flammable or combustible liquids including fuel and lubricating oils is within the scope of this Code. Piping for synthetic lubricants having no flash or fire point need not meet the requirements of para. 122.7.

The designer is cautioned that, among other criteria, static electricity may be generated by the flowing fluid. Additionally, the designer is cautioned of the extreme chilling effect of a liquefied gas flashing to vapor during loss of pressure. This is a factor for determining the lowest expected service temperature relative to the possibility of brittle fracture of materials. Consideration shall also be given to the pressure rise that may occur as a cold fluid absorbs heat from the surroundings.

122.7.2 Materials

(A) Seamless steel or nickel alloy piping materials shall be used in all areas where the line is within 25 ft (7.6 m) of equipment or other lines having an open flame or exposed parts with an operating temperature above 400°F (204°C). Seamless steel or nickel alloy pipe shall also be used for fuel oil systems located downstream of burner shutoff valve(s). The burner shutoff valve(s) shall be located as close to the burner as is practical.

(B) In all other areas, piping systems may include pipe or tube of steel, nickel alloy, ductile iron, copper, or brass construction. Copper tubing shall have a thickness not less than that required by para. 104.1.2(C.3), regardless of pressure. Refer also to paras. 105, 124.6, and 124.7(A)

Wherever materials other than steel or nickel alloy are used, they shall be so located that any spill resulting from the failure of these materials will not unduly expose persons, buildings, or structures, or can be readily controlled by remote valves.

(C) For lubricating oil systems, steel tubing is an acceptable alternative to steel pipe.

(D) Polyethylene (PE) and reinforced thermosetting resin (RTR) pipe may be used for flammable or combustible liquids in buried installations only. The fluid temperatures shall not exceed 140°F (60°C) and pressures shall be limited to 150 psi (1000 kPa). Where such PE or RTR pipe is used in flammable or combustible liquid service, the rules of Appendix III shall be considered mandatory. Where jurisdictional requirements mandate that double containment pipe be used, the rules of Appendix III shall be applied to both the inner and outer pipe.

Particular care must be exercised to prevent damage to RTR piping at the connection to the main or other facility. Precautions shall be taken to prevent crushing or shearing of RTR piping due to external loading or settling of backfill and to prevent damage or pull out from the terminal connection resulting from thermal expansion or contraction.

RTR piping may terminate above ground and outside a building, provided that:

(1) the above ground portion of the RTR pipe is completely enclosed in a conduit or casing of sufficient strength to provide protection from external damage and deterioration. Where a flexible conduit is used, the top of the riser must be attached to a solid support. The conduit or casing shall extend a minimum of 6 in. below grade.

(2) the RTR pipe is not subjected to excessive stresses due to external loading.

122.7.3 Piping Joints

(A) Welded joints shall be used between steel or nickel alloy piping components where practicable. Where bolted flanged joints are necessary, the gasket material shall be suitable for the service. Threaded joints, where unavoidable for connecting to equipment, valves, specialties, or instruments, shall be:

(A.1) in piping of a thickness no less than extra strong regardless of pressure;

(A.2) limited as prescribed in para. 114; and

(A.3) assembled with extreme care to assure leak tightness, using thread sealant suitable for the service.

(B) Threaded joints in copper or brass pipe shall be subject to the same limitations as for steel pipe in (A.1), (A.2), and (A.3), above.

(C) Copper tubing shall be assembled with flared, flareless, or compression type joints as prescribed in

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:26 2005

para. 115, or brazed in accordance with para. 117. Soft solder type joints are prohibited.

(D) RTR pipe shall be adhesive bonded in accordance with the pipe manufacturer's recommended procedures.

(E) Pipe joints dependent on the friction characteristics or resiliency of combustible materials for mechanical or leak tightness of piping shall not be used inside buildings.

(F) Steel tubing shall be assembled with fittings in accordance with para. 115, or with socket weld fittings.

122.7.4 Valves and Specialties. Valves, strainers, meters, and other specialties shall be of steel or nickel alloy construction. As an alternative, ductile or malleable iron or copper alloy valves and specialties may be used, subject to the restrictions in paras. 124.6 and 124.7, where metal temperatures do not exceed 400°F (204°C).

122.8 Piping for Flammable Gases, Toxic Gases or Liquids, or Nonflammable Nontoxic Gases

Although some gases are liquefied for storage or transport, they shall be considered as gases if their Reid vapor pressure is greater than 40 psia [2068.6 mm Hg (absolute)] at 100°F (37.8°C).

122.8.1 Flammable Gas

(A) Some of the common flammable gases are acetylene, ethane, ethylene, hydrogen, methane, propane, butane, and natural or manufactured gas used for fuel. It shall be the designers' responsibility to determine the limiting concentrations (upper and lower explosive limits) and the properties of the gas under consideration. The use of explosive concentrations shall be avoided, or the piping shall be designed to withstand explosive forces.

The designer is further cautioned of the extreme chilling effect of gas during rapid expansion. This is a factor for determining the lowest expected service temperature relative to the possibility of brittle fracture of materials.

(B) Materials. Steel piping, subject to the limitations in para. 105, shall be used for all flammable gases, except as otherwise permitted in (B.2), (B.3), and (B.4) below.

(B.1) Pipe joints shall be welded where practicable, except bolted flanged joints with suitable gaskets may be used where necessary. Threaded joints, where unavoidable for connecting to equipment, valves, specialties, or instruments, shall be:

(B.1.1) in piping of a thickness no less than extra strong regardless of pressure or material;

(B.1.2) limited as prescribed in para. 114, except threaded joints and compression fittings to maximum nominal size of NPS $\frac{3}{4}$ (DN 20) for pressure to 5000 psi (34,000 kPa) are permitted at the connection to the refillable storage containers pressure regulators; and

(B.1.3) assembled with extreme care to assure leak tightness, using thread sealant suitable for the service.

(B.2) For hydrogen systems, the following alternative materials may be used:

(B.2.1) seamless steel tubing with welded joints;

(B.2.2) seamless copper or brass pipe or tubing with brazed, threaded, or compression fitting joints. Threaded fittings shall not exceed NPS $\frac{3}{4}$ (DN 20). For protection against damage, tubing shall be installed in a guarded manner that will prevent damage during construction, operation, or service. Valves with suitable packing, gages, regulators, and other equipment may also consist of copper alloy materials. Safety relief devices shall be vented individually, and connected vent piping shall be designed to convey the fluid, without pockets, to the outside atmosphere; and then directed away from equipment ventilation systems, and vents from other systems.

(B.3) For fuel gas instrumentation and control, seamless copper tubing subject to the following restrictions may be used:

(B.3.1) the design pressure shall not exceed 100 psi (690 kPa);

(B.3.2) tubing shall not exceed $\frac{5}{8}$ in. (15.9 mm) nominal outside diameter;

(B.3.3) all joints shall be made with compression or flared fittings;

(B.3.4) copper tubing shall not be used if the fuel gas contains more than 0.3 grains (19.4 mg) of hydrogen sulfide per 100 cu ft/min (47 liters/sec) of gas at standard conditions;

(B.3.5) consideration shall be given in the design to the lower strength and melting point of copper compared to steel. Adequate support and protection from high ambient temperatures and vibration shall be provided.

(B.3.6) tubing shall be installed in a guarded manner that will prevent damage during construction, operation, and service.

(B.4) Polyethylene (PE) pipe may be used for natural gas service in buried installations only. The fluid temperatures shall not exceed 140°F (60°C), nor be below −20°F (−30°C) and pressures shall be limited to 100 psi (690 kPa). Pipe joints shall be heat fused in accordance with manufacturer's recommended procedures. Where PE pipe is used in flammable gas service, the rules of Appendix III shall be considered mandatory.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:27 2005

(C) Valves and Specialties. Valves, strainers, meters, and other specialities shall be of steel or nickel alloy construction. As as alternative, ductile iron or copper alloy valves and specialities may be used, subject to the restrictions in paras. 124.6 and 124.7, where metal temperatures do not exceed 400°F (204°C).

(D) For in-plant fuel gas distribution system(s) where the use of a full-relieving-capacity relief valve(s) as described in para. 122.5 could create an undue venting hazard, an alternative pressure limiting design may be substituted. The alternative design shall include all provisions below:

(D.1) Tandem Gas Pressure Reducing Valves. To protect the low pressure system, two gas pressure reducing valves capable of independent operation shall be installed in series. Each shall have the capability of closing off against the maximum upstream pressure, and of controlling the pressure on the low pressure side at or below the design pressure of the low pressure system, in the event that the other valve fails open. Control lines must be suitably protected, designed, and installed so that damage to any one control line will not result in over pressurizing the downstream piping.

(D.2) Trip Stop Valve. A fail-safe trip stop valve shall be installed to automatically close, in less than 1 sec, at or below the design pressure of the downstream piping. It shall be a manually reset design. The pressure switch for initiating closure of the trip stop valve shall be hardwired directly to the valve tripping circuit. The pressure switch shall be mounted directly on the low pressure piping without an intervening isolation valve. The trip stop valve shall be located so that it is accessible and protected from mechanical damage and from weather or other ambient conditions which could impair its proper functioning. It may be located upstream or downstream of the tandem gas pressure reducing valves. The trip stop valve and all upstream piping shall be designed for the maximum upstream supply pressure. The trip stop valve may also serve as the upstream isolation valve of a double-block and vent gas supply isolation system. Provision shall be made to safely bleed off the pressure downstream of the trip stop valve.

(D.3) Safety Relief Device. The low pressure system shall be protected from any leakage through the pressure reducing valves, when closed, by a safety relief device(s) constructed and designed in accordance with paras. 107.8.3 and 122.5.3, and sized for the possible leakage rate.

01 **122.8.2 Toxic Fluids (Gas or Liquid)**

(A) For the purpose of this Code, a toxic fluid is one that may be lethal, or capable of producing injury and/or serious illness through contact, inhalation, ingestion, or absorption through any body surface. It shall be the designers' responsibility to adopt the safety precautions published by the relevant fluid industry which may be more stringent than those described in this Code for toxic fluids. In addition, the piping shall be installed in such a manner that will minimize the possibility of damage from external sources.

TABLE 122.8.2(B)
MINIMUM WALL THICKNESS REQUIREMENTS FOR TOXIC FLUID PIPING

	Carbon & Low Alloy Steel (App. A, Tables A-1 & A-2)	Stainless & Nickel Alloy Steel (App. A, Tables A-3 & A-4)
DN 50 (NPS 2) & smaller	Extra strong	Sch. 10S
Larger than DN 50 (NPS 2)	Standard weight	Sch. 5S

(B) Preferably, pipe and pipe fittings should be seamless steel. Wall thickness shall not be less than that in Table 122.8.2(B).

If the fluid is known to be corrosive to the steels in Table 122.8.2(B), the materials and wall thickness selected shall be suitable for the service. (Refer to para. 104.1.2.)

(C) Piping joints shall be made by welding, or by steel socket welding or welding neck flanges with suitable gaskets. Socket welded joints shall not be larger than DN 65 (NPS 2½). Backing rings used for making girth butt welds shall be removed after welding. Miter welds are not permitted. Fabricated branch connections (branch pipe welded directly to run pipe) are not permitted. Threaded joints, where unavoidable, may be used provided that all of the following requirements are met.

(C.1) The pipe thickness shall not be less than extra strong regardless of pressure or type of material.

(C.2) The requirements of para. 114 shall be met except that threaded joints to a maximum nominal size of DN 20 (NPS ¾) for pressure to 34,500 kPa [gage] (5000 psig), or to a maximum nominal size of DN 50 (NPS 2) for pressure to 345 kPa [gage] (50 psig) are permitted at the connections to the refillable storage containers and their associated pressure regulators, shut-off valves, pumps, and meters.

(C.3) Threaded joints are assembled with extreme care to assure leak tightness. The requirements of para.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:27 2005

135.5 shall be met. A thread sealant, suitable for the service, shall be used, except where the joint is to be seal welded.

(D) Steel valves shall be used. Bonnet joints with tapered threads are not permitted. Special consideration shall be given to valve design to prevent stem leakage to the environment. Bonnet or cover plate closures and other body joints shall be one of the following types:

(D.1) union;

(D.2) flanged with suitable gasketing and secured by at least four bolts;

(D.3) proprietary, attached by bolts, lugs, or other substantial means, and having a design that increases gasket compression as fluid pressure increases;

(D.4) threaded with straight threads sufficient for mechanical strength, metal-to-metal seats, and a seal weld made in accordance with para. 127.4.5, all acting in series.

(E) Tubing not larger than $\frac{5}{8}$ in. (16 mm) O.D. with socket welding fittings may be used to connect instruments to the process line. An accessible root valve shall be provided at the process lines to permit isolating the tubing from the process piping. The layout and mounting of tubing shall minimize vibration and exposure to possible damage.

(F) The provisions of para. 102.2.4 are not permitted. The simplified rules for analysis in para. 119.7.1 (A.3) are not permitted. The piping system shall be designed to minimize impact and shock loads. Suitable dynamic analysis shall be made where necessary to avoid or minimize vibration, pulsation, or resonance effects in the piping. The designer is cautioned to consider the possibility of brittle fracture of the steel material selected over the entire range of temperatures to which it may be subjected.

(G) For dry chlorine service between –29°C (–20°F) and 149°C (300°F), the pipe material shall not be less in thickness than seamless extra strong steel.

(H) Toxic fluid piping shall be pneumatic leak tested in accordance with para. 137.5. Alternatively, mass spectrometer or halide leak testing in accordance with para. 137.6, and a hydrostatic test in accordance with para. 137.3 may be performed.

122.8.3 Nonflammable Nontoxic Gas

(A) Piping for nonflammable and nontoxic gases, such as air, oxygen, carbon dioxide, and nitrogen, shall comply with the requirements of this Code, except as otherwise permitted in (B) (below). The designer is cautioned of the extreme chilling effect during rapid expansion. This is a factor for determining the lowest expected service temperature relative to the brittle fracture of the material selected.

(B) Threaded joints with or without compression fittings to a maximum nominal size of NPS $\frac{3}{4}$ for pressures to 5000 psi (34,500 kPa) are permitted at the connection to the refillable storage containers, pressure regulators, shutoff valves, and meters. Refer to Para. 114.

122.9 Piping for Corrosive Liquids and Gases

Where it is necessary to use special material, such as glass and plastics, not listed in Table 126.1, for conveying corrosive or hazardous liquids and gases, the design shall meet the requirements of para. 104.7.

122.10 Temporary Piping Systems

Prior to test and operation of the power plant and its included piping systems, most power and auxiliary service piping are subjected to flushing or chemical cleaning to remove internal foreign material such as rust particles, scale, welding or brazing residue, dirt, etc., which may have accumulated within the piping during the construction period. The flushing or cleaning operation may be accomplished by blowing out with steam or air, by hot oil circulation of oil systems, by acid or caustic fluid circulation, or by other flushing or cleaning methods. Temporary piping, that is piping attached to the permanent piping system whose function is to provide means for introducing and removing the fluids used in the flushing or cleaning operations, shall be designed and constructed to withstand the operating conditions during flushing and cleaning. The following minimum requirements shall apply to temporary piping systems.

(A) Each such system shall be analyzed for compliance with para. 103.

(B) Connections for temporary piping to the permanent piping systems which are intended to remain, shall meet the design and construction requirements of the permanent system to which they are attached.

(C) The temporary systems shall be supported such that forces and moments due to static, dynamic and expansion loadings will not be transferred in an unacceptable manner to the connected permanent piping system. Paragraphs 120 and 121 shall be used as guidance for the design of the temporary piping systems supporting elements.

(D) The temporary systems shall be capable of withstanding the cyclic loadings which occur during the flushing and cleaning operations. Particular attention

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:28 2005

shall be given to the effects of large thrust forces which may be generated during high velocity blowing cycles. Where steam piping is to be subjected to high velocity blowing operations, continuous or automatic draining of trapped or potentially trapped water within the system shall be incorporated. Supports at the exhaust terminals of blowdown piping shall provide for restraint of potential pipe whip.

(E) Where necessary, temporary systems containing cast iron or carbon steel material subject to chemical cleaning shall be prewarmed to avoid the potential for brittle failure of the material.

(F) Where temporary piping has been installed and it does not comply with the requirements of this Code for permanent piping systems, it shall be physically removed or separated from the permanent piping to which it is attached prior to testing of the permanent piping system and prior to plant startup.

122.11 Steam Trap Piping

122.11.1 Drip Lines. Drip lines from piping or equipment operating at different pressures shall not be connected to discharge through the same trap.

122.11.2 Discharge Piping. Trap discharge piping shall be designed to the same pressure as the inlet piping unless the discharge is vented to atmosphere, or is operated under low pressure and has no stop valves. In no case shall the design pressure of trap discharge piping be less than the maximum discharge pressure to which it may be subjected. Where two or more traps discharge into the same header, a stop valve shall be provided in the discharge line from each trap. Where the pressure in the discharge piping can exceed the pressure in the inlet piping, a check valve shall be provided in the trap discharge line. A check valve is not required if either the stop valve or the steam trap is designed to automatically prevent reverse flow and is capable of withstanding a reverse differential pressure equal to the design pressure of the discharge piping.

122.12 Exhaust and Pump Suction Piping

Exhaust and pump suction lines for any service and pressure shall have relief valves of suitable size unless the lines and attached equipment are designed for the maximum pressure to which they may accidentally or otherwise be subjected, or unless a suitable alarm indicator, such as a whistle or free blowing relief valve, is installed where it will warn the operator.

122.13 Pump Discharge Piping

Pump discharge piping from the pump up to and including the valve normally used for isolation or flow control shall be designed for the maximum sustained pressure exerted by the pump and for the highest coincident fluid temperature, as a minimum. Variations in pressure and temperature due to occasional inadvertent operation are permitted as limited in para. 102.2.4 under any of the following conditions:

(A) during operation of overpressure relief devices designed to protect the piping system and the attached equipment;

(B) during a short period of abnormal operation, such as pump overspeed; or

(C) during uncontrolled transients of pressure or temperature.

122.14 District Heating and Steam Distribution Systems

122.14.1 General. Where pressure reducing valves are used, one or more relief devices or safety valves shall be provided on the low pressure side of the system. Otherwise, the piping and equipment on the low pressure side of the system shall be designed to withstand the upstream design pressure. The relief or safety devices shall be located adjoining or as close as practicable to the reducing valve. The combined relieving capacity provided shall be such that the design pressure of the low pressure system will not be exceeded if the reducing valve fails open.

122.14.2 Alternative Systems. In district heating and steam distribution systems where the steam pressure does not exceed 400 psi (2750 kPa) and where the use of relief valves as described in para. 122.14.1 is not feasible (e.g., because there is no acceptable discharge location for the vent piping), alternative designs may be substituted for the relief devices. In either case, it is recommended that alarms be provided which will reliably warn the operator of failure of any pressure reducing valve.

(A) Tandem Steam Pressure Reducing Valves. Two or more steam pressure reducing valves capable of independent operation may be installed in series, each set at or below the safe working pressure of the equipment and piping system served. In this case, no relief device is required.

Each pressure reducing valve shall have the capability of closing off against full line pressure, and of controlling the reduced pressure at or below the design pressure

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:28 2005

of the low pressure system, in the event that the other valve fails open.

(B) Trip Stop Valves. A trip stop steam valve set to close at or below the design pressure of the low pressure system may be used in place of a second reducing valve or a relief valve.

CHAPTER III
MATERIALS

01 **123 General Requirements**

Chapter III contains limitations and required qualifications for materials based on their inherent properties. Use of these materials in piping systems is also subject to requirements and limitations in other parts of this Code.

123.1 Materials and Specifications

123.1.1 Listed Materials. Material meeting the following requirements shall be considered listed and acceptable materials.

(A) Materials for which allowable stress values are listed in Appendix A or which have been approved by the procedure established by (C) below.

(B) A material conforming to a specification for which allowable stresses are not listed in Appendix A is acceptable provided its use is not specifically prohibited by this Code Section and it satisfies one of the following requirements.

(B.1) It is referenced in a standard listed in Table 126.1. Such a material shall be used only within the scope of and in the product form covered by the referencing standard listed in Table 126.1.

(B.2) It is referenced in other parts of this Code Section and shall be used only within the scope of and in the product form permitted by the referencing text.

(C) Where it is desired to use materials which are not currently acceptable under the rules of this Code Section, written application shall be made to the Committee fully describing the proposed material and the contemplated use. Such material shall not be considered listed and not used as a listed material until it has been approved by the Committee and allowable stress values have been assigned. Details of information which should be included in such applications are given in Appendix VI. See para. 123.1.2.

(D) Materials conforming to ASME SA or SB specifications may be used interchangeably with material specified to the listed ASTM A or B specifications of the same number, except where the requirements of para. 123.2.2 apply.

123.1.2 Unlisted Materials Materials other than those meeting the requirements of para. 123.1.1 shall be considered unlisted materials. Such unlisted materials may only be used for nonboiler external piping provided they satisfy all of the following requirements:

(A) Unlisted materials are certified by the material manufacturer to satisfy the requirements of a specification listed in any Code Section of the ASME B31 Code for Pressure Piping, the ASME Boiler and Pressure Vessel Code, Section II, Part D, or to a published specification covering chemistry, physical and mechanical properties, method and process of manufacture, heat treatment, and quality control.

(B) The allowable stresses of the unlisted materials shall be determined in accordance with the rules of para. 102.3.1(C).

(C) Unlisted materials shall be qualified for service within a stated range of minimum and maximum temperatures based upon data associated with successful experience, tests, or analysis; or a combination thereof.

(D) The designer shall document the owner's acceptance for use of unlisted material.

(E) All other requirements of this Code are satisfied.

123.1.5 Size or Thickness. Materials outside the limits of size or thickness given in the title or scope clause of any specification listed in Table 126.1 may be used if the material is in compliance with the other requirements of the specification, and no other similar limitation is given in the rules for construction.

123.1.6 Marking of Materials or Products. Materials or products marked as meeting the requirements for more than one grade, type, or alloy of a material specification or multiple specifications, are acceptable provided: 01

(A) one of the markings includes the material specification, grade, class, and type or alloy of the material permitted by this Code and the material meets all the requirements of that specification;

(B) the appropriate allowable stress for the specified grade, type, or alloy of a material specification from Appendix A is used;

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:29 2005

(C) all other requirements of this Code are satisfied for the material permitted.

123.2 Piping Components

123.2.1 General. Materials which do not comply with the rules of para. 123.1 may be used for flared, flareless, and compression type tubing fittings, provided that the requirements of para. 115 are met.

123.2.2 Boiler External Piping

(A) Materials for boiler external piping, as defined in para. 100.1.2(A), shall be specified in accordance with ASME SA, SB, or SFA specifications. Material produced under an ASTM specification may be used, provided that the requirements of the ASTM specification are identical or more stringent than the ASME specification for the Grade, Class, or Type produced. The material manufacturer or component manufacturer shall certify, with evidence acceptable to the Authorized Inspector, that the ASME specification requirements have been met. Materials produced to ASME or ASTM material specifications are not limited as to country of origin.

(B) Materials which are not fully identified shall comply with PG-10 of Section I of the ASME Boiler and Pressure Vessel Code.

123.3 Pipe Supporting Elements

Except as permitted by paras. 121.7.2(C) and (D), steel materials shall be used for pipe supporting elements. Steel materials which do not comply with the rules of para. 123.1 may be used for pipe supporting elements, provided the rules of para. 121.2(C) are met.

124 LIMITATIONS ON MATERIALS

124.1 General

The materials listed in the Allowable Stress Tables A-1 through A-9, Appendix A, shall not be used at design temperatures above those for which stress values are given except as permitted by para. 122.6.2(G).

124.2 Steel

(A) Upon prolonged exposure to temperatures above 775°F (415°C), the carbide phase of plain carbon steel, plain nickel alloy steel, carbon-manganese alloy steel, manganese-vanadium alloy steel, and carbon-silicon steel may be converted to graphite.

(B) Upon prolonged exposure to temperatures above 875°F (470°C), the carbide phase of alloy steels, such as carbon-molybdenum, manganese-molybdenum-vanadium, manganese-chromium-vanadium, and chromium-vanadium, may be converted to graphite.

(C) Carbon or alloy steel having carbon content of more than 0.35% shall not be used in welded construction or be shaped by oxygen cutting process or other thermal cutting processes.

(D) Where low alloy (3% chromium or less) steels are used at temperatures above 850°F, the carbon content of the base material and weld filler metal shall be 0.05% or higher.

124.4 Cast Gray Iron

The low ductility of cast gray iron may result in sudden failure if shock loading (pressure, temperature or mechanical) should occur. Possible shock loadings and consequences of failure must be considered before specifying the use of such material. Cast iron components may be used within the nonshock pressure-temperature ratings established by the standards and specifications herein and in para. 105.2.1(B). Castings to ASME SA-278 and ASTM A 278 shall have maximum limits of 250 psig [1725 kPa (gage)] and 450°F (230°C).

The following referenced paragraphs prohibit or restrict the use of gray cast iron for certain applications or to certain pressure-temperature ratings:

Pipe Supports	121.7.2(C)
BEP Blowoff	122.1.4(A.3)
BEP Blowdown	122.1.4(B.3)
BEP Valves and Fittings	122.1.7
Blowoff Valves	122.1.7(C.5) & (C.6)
Non-BEP Blowoff	122.2(A.1)
Non-BEP Blowdown	122.2(A.2)
Flammable or Combustible Liquids	122.7.3
Flammable Gases	122.8.1(B)
Toxic Gases or Liquids	122.8.2

124.5 Malleable Iron

Certain types of malleable iron have low ductility characteristics and may be subject to brittle fracture. Malleable iron may be used for design conditions not to exceed 350 psig [2415 kPa (gage)] or 450°F (230°C).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:29 2005

The following referenced paragraphs prohibit or restrict the use of malleable iron for certain applications or to certain pressure-temperature ratings:

Pipe Supports	121.7.2(D)
BEP Blowoff	122.1.4(A.3)
BEP Blowdown	122.1.4(B.3)
Non-BEP Blowoff	122.2(A.1)
Non-BEP Blowdown	122.2(A.2)
Flammable or Combustible Liquids	122.7.3(C)
Flammable Gases	122.8.1(B)
Toxic Gases or Liquids	122.8.2

124.6 Ductile (Nodular) Iron

Ductile (nodular) iron components conforming to ANSI B16.42 may be used under the following conditions.

(A) Components for boiler external piping shall be used only within the following limitations.

(A.1) Only ASME SA-395 material may be used.

(A.2) Design pressure shall not exceed 350 psig [2415 kPa (gage)].

(A.3) Design temperature shall not exceed 450°F (230°C).

(B) Welding shall not be used, either in fabrication of the components or in their assembly as a part of a piping system.

(C) The following referenced paragraphs prohibit or restrict the use of ductile iron for certain applications or to certain pressure-temperature ratings:

BEP Blowoff	122.1.4(A.3)
BEP Blowdown	122.1.4(B.3)
BEP Blowoff Valves	122.1.7(C.5)&(C.6)
Non-BEP Blowoff	122.2(A.1)
Non-BEP Blowdown	122.2(A.2)
Flammable or Combustible Liquids	122.7.3(B)
Flammable Gases	122.8.1(D)
Toxic Gases or Liquids	122.8.2
Pipe Supports	123.3

124.7 Nonferrous Metals

Nonferrous metals may be used in piping systems under the following conditions.

(A) The melting points of copper, copper alloys, aluminum, and aluminum alloys must be considered particularly where there is a fire hazard.

(B) The Designer shall consider the possibility of galvanic corrosion when combinations of dissimilar metals, such as copper, aluminum, and their alloys, are used in conjunction with each other or with steel or other metals in the presence of an electrolyte.

(C) Threaded Connections. A suitable thread compound shall be used in making up threaded joints in aluminum pipe to prevent seizing which might cause leakage and perhaps prevent disassembly. Pipe in the annealed temper should not be threaded.

124.8 Nonmetallic Pipe

This Code recognizes the existence of a wide variety of nonmetallic piping materials which may be used on corrosive (either internal or external) or other specialized applications. Extreme care must be taken in their selection as their design properties vary greatly and depend upon the material, type and grade. Particular consideration shall be given to the possibility of:

(A) destruction where fire hazard is involved;

(B) decrease in tensile strength at slight increase in temperature; and

(C) effects of toxicity. Another consideration is that of providing adequate support for the flexible pipe.

For nonmandatory rules for nonmetallic piping, see Appendix III of this Code.

124.9 Deterioration of Materials in Service

It is the responsibility of the engineer to select materials suitable for the intended application. Some guideline for selection of protective coatings for metallic piping are provided in Appendix IV.

125 MATERIALS APPLIED TO MISCELLANEOUS PARTS

125.1 Gaskets

Limitations on gasket materials are covered in para. 108.4.

125.2 Bolting

Limitations on bolting materials are covered in para. 108.5.

CHAPTER IV
DIMENSIONAL REQUIREMENTS

126 MATERIAL SPECIFICATIONS AND STANDARDS FOR STANDARD AND NONSTANDARD PIPING COMPONENTS

126.1 Standard Piping Components

Dimensions of standard piping components shall comply with the standards and specifications listed in Table 126.1 in accordance with para. 100.

126.2 Nonstandard Piping Components

When nonstandard piping components are designed in accordance with para. 104, adherence to dimensional standards of ANSI and ASME is strongly recommended when practicable.

126.3 Referenced Documents

The documents listed in Table 126.1 may contain references to codes, standards, or specifications not listed in this Table. Such unlisted codes, standards, or specifications are to be used only in the context of the listed documents in which they appear.

Where documents listed in Table 126.1 contain design rules which are in conflict with this Code, the design rules of this Code shall govern.

The fabrication, assembly, examination, inspection, and testing requirements of Chapters V and VI apply to the construction of piping systems. These requirements are not applicable to piping components manufactured in accordance with the documents listed in Table 126.1 unless specifically so stated.

CHAPTER V
FABRICATION, ASSEMBLY, AND ERECTION

127 WELDING

127.1 General

Piping systems shall be constructed in accordance with the requirements of this Chapter and of materials that have been manufactured in accordance with the requirements of Chapter IV. These requirements apply to all fabrication, assembly, and erection operations, whether performed in a shop or at a construction site. The following applies essentially to the welding of ferrous materials. The welding of aluminum, copper, etc., requires different preparations and procedures.

127.1.1 The welding processes that are to be used under this part of this Code shall meet all the test requirements of Section IX of the ASME Boiler and Pressure Vessel Code.

127.2 Material

127.2.1 Filler Metal. All filler metal, including consumable insert material, shall comply with the requirements of Section IX, ASME Boiler and Pressure Vessel Code. A filler metal not incorporated in Section IX may be used if a procedure qualification test is first successfully made in accordance with Section IX. Filler metals with less than 0.05% carbon content shall not be used for high temperature applications (above 850°F) in low alloy steels due to reduced creep rupture properties.

127.2.2 Backing Rings. Backing rings, when used, shall conform to the following requirements:

(A) Ferrous Rings. Ferrous metal backing rings which become a permanent part of the weld shall be made from material of weldable quality, compatible with the base material and the sulfur content shall not exceed 0.05%.

(A.1) Backing rings may be of the continuous machined or split band type.

(A.2) If two abutting surfaces are to be welded to a third member used as a backing ring and one or two of the three members are ferritic and the other member or members are austenitic, the satisfactory use of such materials shall be determined by the WPS qualified as required in para. 127.5.

(A.3) Backing strips used at longitudinal welded joints shall be removed.

(B) Nonferrous and Nonmetallic Rings. Backing rings of nonferrous or nonmetallic materials may be used for backing provided they are included in a WPS as required in para. 127.5. Nonmetallic or nonfusing rings shall be removed.

127.2.3 Consumable Inserts. Consumable inserts may be used provided they are made from material compatible with the chemical and physical properties of the base material. Qualification of the WPS shall be as required by para. 127.5.

127.3 Preparation for Welding

(A) End Preparation

(A.1) Oxygen or arc cutting is acceptable only if the cut is reasonably smooth and true, and all slag is cleaned from the flame cut surfaces. Discoloration which may remain on the flame cut surface is not considered to be detrimental oxidation.

(A.2) Butt-welding end preparation dimensions contained in ASME B16.25 or any other end preparation which meets the WPS are acceptable.

(A.3) If piping component ends are bored, such boring shall not result in the finished wall thickness after welding less than the minimum design thickness. Where necessary, weld metal of the appropriate analysis may be deposited on the inside or outside of the piping component to provide sufficient material for machining to insure satisfactory fitting of rings.

(A.4) If the piping component ends are upset, they may be bored to allow for a completely recessed backing ring, provided the remaining net thickness of the finished ends is not less than the minimum design thickness.

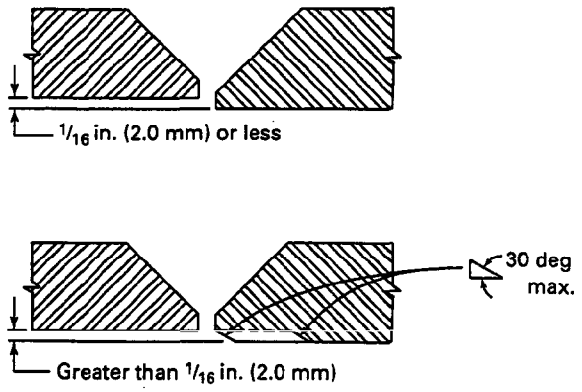

FIG 127.3 BUTT WELDING OF PIPING COMPONENTS WITH INTERNAL MISALIGNMENT

(B) Cleaning. Surfaces for welding shall be clean and shall be free from paint, oil, rust, scale, or other material which is detrimental to welding.

(C) Alignment. The inside diameters of piping components to be butt welded shall be aligned as accurately as is practicable within existing commercial tolerances on diameters, wall thicknesses, and out-of-roundness. Alignment shall be preserved during welding. The internal misalignment of the ends to be joined shall not exceed 1/16 in. (2.0 mm) unless the piping design specifically states a different allowable misalignment.

When the internal misalignment exceeds the allowable, it is preferred that the component with the wall extending internally be internally trimmed per Fig. 127.3. However, trimming shall result in a piping component thickness not less than the minimum design thickness and the change in contour shall not exceed 30 deg (see Fig. 127.3).

(D) Spacing. The root opening of the joint shall be as given in the WPS.

(E) Socket Weld Assembly. In assembly of the joint before welding, the pipe or tube shall be inserted into the socket to the maximum depth and then withdrawn approximately 1/16 in. (2.0 mm) away from contact between the end of the pipe and the shoulder of the socket [see Figs. 127.4.4(B) and (C)]. In sleeve type joints without internal shoulder, there shall be a distance of approximately 1/16 in. (2.0 mm) between the butting ends of the pipe or tube.

The fit between the socket and the pipe shall conform to applicable standards for socket weld fittings and in no case shall the inside diameter of the socket or sleeve exceed the outside diameter of the pipe or tube by more than 0.080 in. (2.0 mm).

127.4 Procedure

127.4.1 General

(A) Qualification of the WPS to be used, and of the performance of welders and operators, is required, and shall comply with the requirements of para. 127.5.

(B) No welding shall be done if there is impingement of rain, snow, sleet, or high wind on the weld area.

(C) Tack welds permitted to remain in the finished weld shall be made by a qualified welder. Tack welds made by an unqualified welder shall be removed. Tack welds which remain shall be made with an electrode and WPS which is the same as or equivalent to the electrode and WPS to be used for the first pass. The stopping and starting ends shall be prepared by grinding or other means so that they can be satisfactorily incorporated into the final weld. Tack welds which have cracked shall be removed.

(D) CAUTION: Arc strikes outside the area of the intended weld should be avoided on any base metal.

127.4.2 Girth Butt Welds

(A) Girth butt welds shall be complete penetration welds and shall be made with a single vee, double vee, or other suitable type of groove, with or without backing rings or consumable inserts. The depth of the weld measured between the inside surface of the weld preparation and the outside surface of the pipe shall not be less than the minimum thickness required by Chapter II for the particular size and wall of pipe used.

(B) In order to avoid abrupt transitions in the contour of the finished weld, the requirements of (B.1) through (B.4) below shall be met.

(B.1) When components with different outside diameters or wall thicknesses are welded together, the welding end of the component with the larger outside diameter shall fall within the envelope defined by solid lines in Fig. 127.4.2. The weld shall form a gradual transition not exceeding a slope of 30 deg from the smaller to the larger diameter component. This condition may be met by adding welding filler material, if necessary, beyond what would otherwise be the edge of the weld.

(B.2) When both components to be welded (other than pipe to pipe) have a transition from a thicker section to the weld end preparation, the included angle between the surface of the weld and the surface of either of the components shall not be less than 150 deg Refer to para. 119.3(B) for additional concerns related to this design.

(B.3) When welding pipe to pipe, the surface of the

GENERAL NOTES:

(a) The value of t_m is whichever of the following is applicable:
  (1) as defined in para. 104.1.2(A);
  (2) the minimum ordered wall thickness of the cylindrical welding end of a component or fitting (or the thinner of the two) when the joint is between two components.

(b) The maximum envelope is defined by solid lines.

NOTES:

(1) Weld is shown for illustration only.
(2) The weld transition and weld reinforcement shall comply with paras. 127.4.2(B) and (C-2) and may be outside the maximum envelope.
(3) The maximum thickness at the end of the component is:
  (a) the greater of (t_m + 0.15 in.) or $1.15t_m$ when ordered on a minimum wall basis;
  (b) the greater of (t_m + 0.15 in.) or $1.10t_{nom}$ when ordered on a nominal wall basis.

FIG. 127.4.2 WELDING END TRANSITION — MAXIMUM ENVELOPE

TABLE 127.4.2
REINFORCEMENT OF GIRTH AND LONGITUDINAL BUTT WELDS

Thickness of Base Metal, in. (mm)	Maximum Thickness of Reinforcement for Design Temperature					
	> 750°F (400°C)		350°F–750°F (175°C–400°C)		< 350°F (175°C)	
	in.	mm	in.	mm	in.	mm
Up to 1/8 (3.0), incl.	1/16	2.0	3/32	2.5	3/16	5.0
Over 1/8 to 3/16 (3.0 to 5.0), incl.	1/16	2.0	1/8	3.0	3/16	5.0
Over 3/16 to 1/2 (5.0 to 13.0), incl.	1/16	2.0	5/32	4.0	3/16	5.0
Over 1/2 to 1 (13.0 to 25.0), incl.	3/32	2.5	3/16	5.0	3/16	5.0
Over 1 to 2 (25.0 to 50.0), incl.	1/8	3.0	1/4	6.0	1/4	6.0
Over 2 (50.0)	5/32	4.0	The greater of 1/4 in. (6 mm) or 1/8 times the width of the weld in inches (millimeters).			

GENERAL NOTES:

(a) For double welded butt joints, this limitation on reinforcement given above shall apply separately to both inside and outside surfaces of the joint.

(b) For single welded butt joints, the reinforcement limits given above shall apply to the outside surface of the joint only.

(c) The thickness of weld reinforcement shall be based on the thickness of the thinner of the materials being joined.

(d) The weld reinforcement thicknesses shall be determined from the higher of the abutting surfaces involved.

(e) Weld reinforcement may be removed if so desired.

weld shall, as a minimum, be flush with the outer surface of the pipe, except as permitted in para. 127.4.2(B.4).

(B.4) For welds made without the addition of filler metal, concavity shall be limited to 1/32 in. (1 mm) below the outside surface of the pipe, but shall not encroach upon minimum required thickness.

(C) As-welded surfaces are permitted; however, the surface of welds shall be sufficiently free from coarse ripples, grooves, overlaps, abrupt ridges, and valleys to meet the following.

(C.1) The surface condition of the finished welds shall be suitable for the proper interpretation of radiographic and other nondestructive examinations when nondestructive examinations are required by Table 136.4. In those cases where there is a question regarding the surface condition on the interpretation of a radiographic film, the film shall be compared to the actual weld surface for interpretation and determination of acceptability.

(C.2) Reinforcements are permitted in accordance with Table 127.4.2.

(C.3) Undercuts shall not exceed 1/32 in. (1.0 mm) and shall not encroach on the minimum required section thickness.

(C.4) If the surface of the weld requires grinding to meet the above criteria, care shall be taken to avoid reducing the weld or base material below the minimum required thickness.

(C.5) Concavity on the root side of a single welded circumferential butt weld is permitted when the resulting thickness of the weld is at least equal to the thickness of the thinner member of the two sections being joined and the contour of the concavity is smooth without sharp edges. The internal condition of the root surface of a girth weld, which has been examined by radiography, is acceptable only when there is a gradual change in the density, as indicated in the radiograph. If a girth weld is not designated to be examined by radiography, a visual examination may be performed at welds which are readily accessible.

127.4.3 Longitudinal Butt Welds. Longitudinal butt welds not covered by the applicable material specifications listed in Table 126.1 shall meet the requirements for girth butt welds in para. 127.4.2.

127.4.4 Fillet Welds. In making fillet welds, the weld metal shall be deposited in such a way as to secure adequate penetration into the base metal at the root of the weld.

Fillet welds may vary from convex to concave. The size of a fillet weld is determined as shown in Fig. 127.4.4(A). Typical minimum fillet weld details for slip-on flanges and socket-welding components are shown in Figs. 127.4.4(B) and (C).

(a) Convex Equal Leg Fillet Weld

(b) Concave Equal Leg Fillet Weld

(c) Convex Unequal Leg Fillet Weld

(d) Concave Unequal Leg Fillet Weld

GENERAL NOTES:

(a) The "size" of an equal leg fillet weld shall be described by the leg length of the largest inscribed isoceles triangle.

(b) The "size" of an unequal leg fillet weld shall be described using both leg lengths and their location on the members to be joined.

(c) Angle θ, as noted in the above figures, may vary from the 90 deg angle as shown based on the angle between the surfaces to be welded.

(d) For an equal leg fillet weld where the angle θ between the members being joined is 90 deg, the theoretical throat shall be 0.7 × leg length. For other fillet welds, the theoretical throat shall be based on the leg lengths and the angle θ between the members to be joined.

(e) For all fillet welds, particularly unequal leg fillet welds with angle θ less than 90 deg, the theoretical throat shall lie within the cross section of the deposited weld metal and shall not be less than the minimum distance through the weld.

FIG. 127.4.4(A) FILLET WELD SIZE

127.4.5 Seal Welds. Where seal welding of threaded joints is performed, threads shall be entirely covered by the seal weld. Seal welding shall be done by qualified welders.

127.4.8 Welded Branch Connections

(A) Welded branch connections shall be made with full penetration welds, except as allowed in para. 127.4.8(F). Figures 127.4.8(A), (B), and (C) show typical details of branch connections with and without added reinforcement. No attempt has been made to show all acceptable types of construction and the fact that a certain type of construction is illustrated does not indicate that it is recommended over other types not illustrated.

(B) Figure 127.4.8(D) shows basic types of weld attachments used in the fabrication of branch connections. The location and minimum size of these attach-

(3) Refer to para. 122.1.1(H) for limitations of use.

FIG. 127.4.4(B) WELDING DETAILS FOR SLIP-ON AND SOCKET-WELDING FLANGES; SOME ACCEPTABLE TYPES OF FLANGE ATTACHMENT WELDS

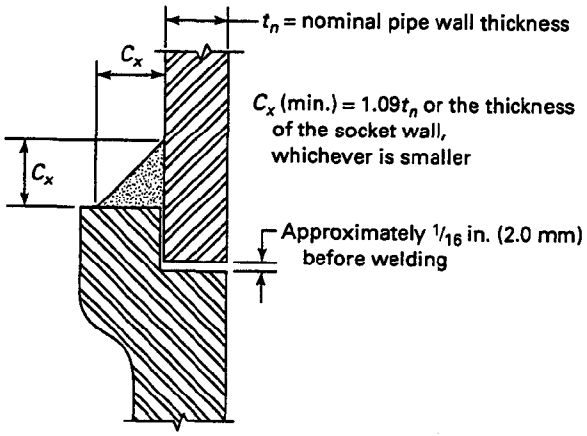

FIG. 127.4.4(C) MINIMUM WELDING DIMENSIONS REQUIRED FOR SOCKET WELDING COMPONENTS OTHER THAN FLANGES

ment welds shall conform to the requirements of para. 127.4.8. Welds shall be calculated in accordance with para. 104.3.1 but shall not be less than the sizes shown in Fig. 127.4.8(D).

The notations and symbols used in this paragraph and in Fig. 127.4.8(D) are as follows:

t_c = the smaller of 1/4 in. (6.0 mm) or $0.7t_{nb}$

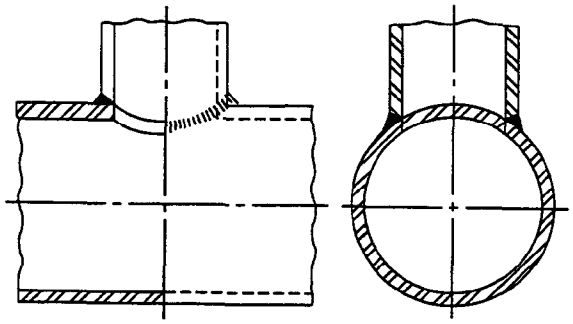

FIG. 127.4.8(A) TYPICAL WELDED BRANCH CONNECTION WITHOUT ADDITIONAL REINFORCEMENT

t_{nr} = nominal thickness of reinforcing element (ring or saddle), in. (mm)
t_{min} = the smaller of t_{nb} or t_{nr}
t_{nb} = nominal thickness of branch wall, in. (mm)
t_{nh} = nominal thickness of header wall, in. (mm)

(C) Figure 127.4.8(E) shows branch connections made by welding half couplings or adapters directly to the run pipe.

These branch connections and specially made integrally reinforced branch connection fittings which abut the outside surface of the run wall, or which are inserted through an opening cut in the run wall, shall have

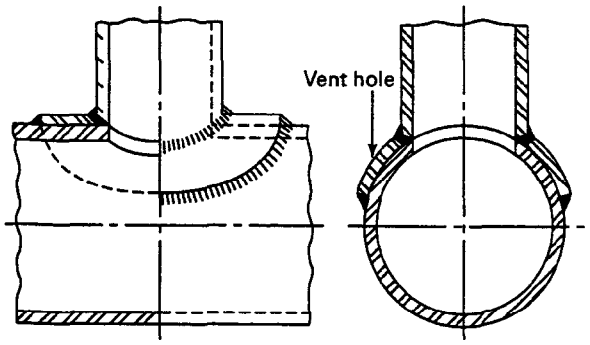

FIG. 127.4.8(B) TYPICAL WELDED BRANCH CONNECTION WITH ADDITIONAL REINFORCEMENT

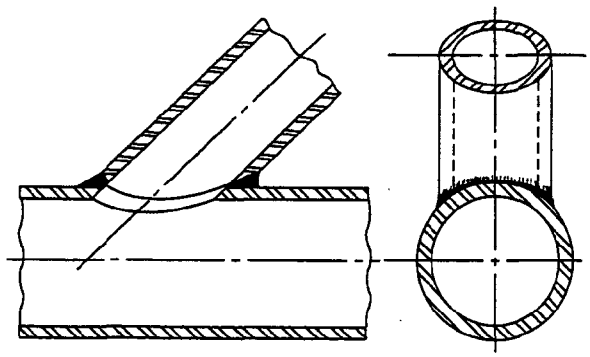

FIG. 127.4.8(C) TYPICAL WELDED ANGULAR BRANCH CONNECTION WITHOUT ADDITIONAL REINFORCEMENT

opening and branch contour to provide a good fit and shall be attached by means of full penetration groove welds except as otherwise permitted in (F) below.

The full penetration groove welds shall be finished with cover fillet welds and meet the requirements of para. 104. The cover fillet welds shall have a minimum throat dimension not less than that shown in Fig. 127.4.8(E).

(D) In branch connections having reinforcement pads or saddles, the reinforcement shall be attached by welds at the outer edge and at the branch periphery as follows.

(D.1) If the weld joining the added reinforcement to the branch is a full penetration groove weld, it shall be finished with a cover fillet weld having a minimum throat dimension not less than t_c; the weld at the outer edge, joining the added reinforcement to the run, shall be a fillet weld with a minimum throat dimension of $0.5t_{nr}$.

(D.2) If the weld joining the added reinforcement to the branch is a fillet weld, the throat dimension shall not be less than $0.7t_{min}$. The weld at the outer edge joining the outer reinforcement to the run shall also be a fillet weld with a minimum throat dimension of $0.5t_{nr}$.

(E) When rings or saddles are used, a vent hole shall be provided (at the side and not at the crotch) in the ring or saddle to reveal leakage in the weld between branch and main run and to provide venting during welding and heat treating operations. Rings or saddles may be made in more than one piece if the joints between the pieces have strength equivalent to ring or saddle parent metal and if each piece is provided with a vent hole. A good fit shall be provided between reinforcing rings or saddles and the parts to which they are attached.

(F) Branch connections NPS 2 and smaller which do not require reinforcements (see para. 104.3) may be constructed as shown in Fig. 127.4.8(F). The groove welds shall be finished with cover fillet welds with a minimum throat dimension not less than that shown in Fig. 127.4.8(F). This construction shall not be used at design temperatures greater than 750°F (400°C) nor at design pressures greater than 1025 psi (7100 kPa).

127.4.9 Attachment Welds. Structural attachments may be made by complete penetration, partial penetration, or fillet welds.

(A) Low energy capacitor discharge welding may be used for the welding of temporary attachments directly to pressure parts, provided that they be removed prior to subjecting the piping system to operating pressure or temperature. After their removal, the affected areas shall be examined in accordance with para. 136.4. Performance and procedure qualifications are not required.

This method of welding may also be used for the permanent attachment of nonstructural items, such as strain gages or thermocouples, provided that:

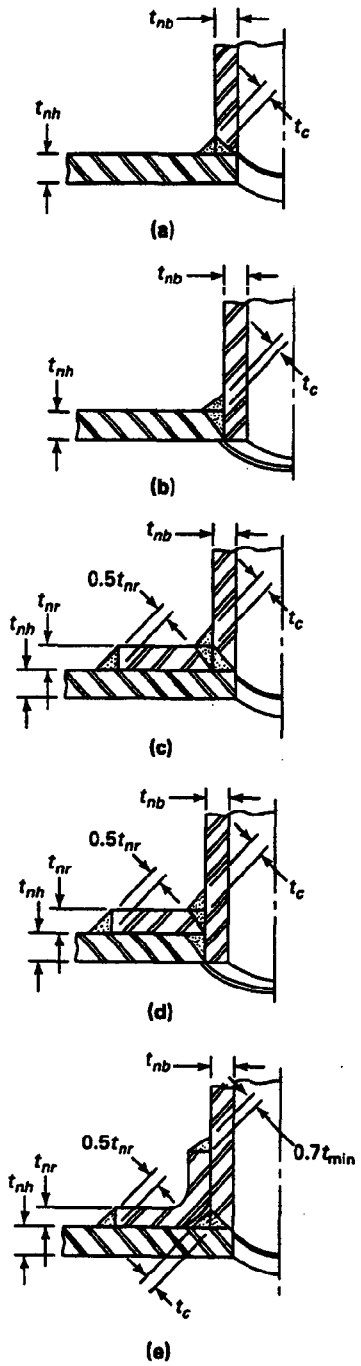
(A.1) a welding procedure specification is prepared describing the capacitor discharge equipment, the materials to be joined, and the techniques of application; the qualification of the procedure is not required;

(A.2) the minimum thickness of the material to which the attachment is to be made is 0.090 in. (2.3 mm);

(A.3) the power input is limited to less than 125 W-sec.

127.4.10 Heat Treatment. Preheat and postweld heat treatment for welds shall be in accordance with para. 131 or 132 as applicable.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:35 2005



GENERAL NOTE: Weld dimensions may be larger than the minimum values shown here.

FIG. 127.4.8(D) SOME ACCEPTABLE TYPES OF WELDED BRANCH ATTACHMENT DETAILS SHOWING MINIMUM ACCEPTABLE WELDS

127.4.11 Repair Welding

(A) Defect Removal. All defects in welds or base materials requiring repair shall be removed by flame or arc gouging, grinding, chipping, or machining. Preheating may be required for flame or arc gouging on certain alloy materials of the air hardening type in order to prevent surface checking or cracking adjacent to the flame or arc gouged surface.

(B) Repair Welds. Repair welds shall be made in accordance with a WPS using qualified welders or welding operators (see para. 127.5), recognizing that the cavity to be repair welded may differ in contour and dimension from a normal joint preparation and may present different restraint conditions. The types, extent, and methods of examination shall be in accordance with Table 136.4. For repairs to welds the minimum examination shall be the same method that revealed the defect in the original weld. For repairs to base material, the minimum examination shall be the same as required for butt welds.

127.5 Qualification

127.5.1 General. Qualification of the WPS to be used, and of the performance of welders and welding operators, is required, and shall comply with the requirements of the ASME Boiler and Pressure Vessel Code (Section IX) except as modified herein.

Certain materials listed in Appendix A do not appear in ASME Section IX P-Number groups. Where these materials have been assigned P-Numbers in Appendix A, they may be welded under this Code for nonboiler external piping only without separate qualification as if they were listed in ASME Section IX.

127.5.2 Welding Responsibility. Each employer (see para. 100.2) shall be responsible for the welding performed by his organization and the performance of welders or welding operators employed by that organization.

127.5.3 Qualification Responsibility

(A) Procedures. Each employer shall be responsible for qualifying any WPS that he intends to have used by personnel of his organization. However, to avoid duplication of effort, and subject to approval of the owner, a WPS qualified by a technically competent group or agency may be used:

(A.1) if the group or agency qualifying the WPS meets all of the procedure qualification requirements of this Code;

(A.2) if the fabricator accepts the WPS thus qualified;

(a) Branch Connection Using ASME B16.11 Forged Steel Socket-Welding or Threaded Half Coupling [See Note (1)]

(b) Branch Connection Using Forged Steel Socket-Welding or Threaded Adapter for Pressure and Temperature Conditions Greater Than Permitted for ASME B16.11 Forged Steel Fittings

NOTE:
(1) Refer to para. 104.3.1(C.2) for branch connections not requiring reinforcement calculations.

FIG. 127.4.8(E) TYPICAL FULL PENETRATION WELD BRANCH CONNECTIONS FOR NPS 3 AND SMALLER HALF COUPLINGS OR ADAPTERS

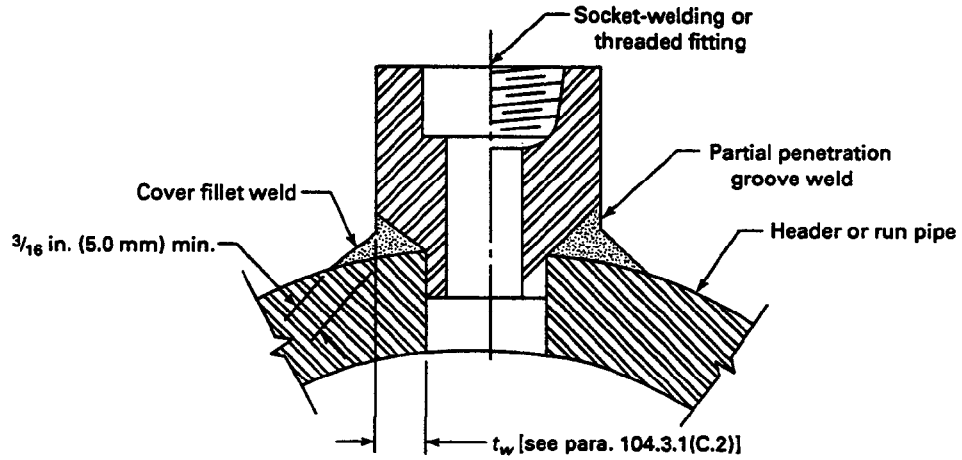

FIG. 127.4.8(F) TYPICAL PARTIAL PENETRATION WELD BRANCH CONNECTION FOR NPS 2 AND SMALLER FITTINGS

(A.3) if the user of the WPS has qualified at least one welder using the WPS;

(A.4) if the user of the WPS assumes specific responsibility for the procedure qualification work done for him by signing the records required by para. 127.6.

All four of the above conditions shall be met before a WPS thus qualified may be used.

(B) Welders and Welding Operators. Each employer shall be responsible for qualifying all the welders and welding operators employed by him.

However, to avoid duplication of effort, he may accept a Welder/Welding Operator Performance Qualification (WPQ) made by a previous employer (subject to the approval of the owner or his agent) on piping using the same or an equivalent procedure wherein the essential variables are within the limits established in Section IX,

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:35 2005

ASME Boiler and Pressure Vessel Code. An employer accepting such qualification tests by a previous employer shall obtain a copy (from the previous employer) of the WPQ, showing the name of the employer by whom the welders or welding operators were qualified, the dates of such qualification, and evidence that the welder or welding operator has maintained qualification in accordance with QW-322 of Section IX, ASME Boiler and Pressure Vessel Code. The employer shall then prepare and sign the record required in para. 127.6 accepting responsibility for the ability of the welder or welding operator.

01 **127.5.4 Standard Welding Procedure Specifications.** Standard Welding Procedure Specifications published by the American Welding Society and listed in Appendix E of Section IX of the ASME Boiler and Pressure Vessel Code are permitted for Code construction within the limitations established by Article V of ASME Section IX.

127.6 Welding Records

The employer shall maintain a record (WPS and/or WPQ) signed by him, and available to the purchaser or his agent and the inspector, of the WPSs used and the welders and/or welding operators employed by him, showing the date and results of procedure and performance qualification.

The WPQ shall also show the identification symbol assigned to the welder or welding operator employed by him, and the employer shall use this symbol to identify the welding performed by the welder or welding operator. This may be accomplished by the application of the symbol on the weld joint in a manner specified by the employer. Alternatively, the employer shall maintain records which identify the weld(s) made by the welder or welding operator.

128 BRAZING

128.1 General

128.1.1 The brazing processes that are to be used under this part of the Code shall meet all the test requirements of Section IX of the ASME Boiler and Pressure Vessel Code.

128.2 Materials

128.2.1 Filler Metal. The filler metal shall melt and flow freely within the desired temperature range and, in conjunction with a suitable flux or controlled atmosphere, shall wet and adhere to the surfaces to be joined.

128.2.2 Flux. Fluxes that are fluid and chemically active at the brazing temperature shall be used when necessary to prevent oxidation of the filler metal and the surfaces to be joined and to promote free flowing of the filler metal.

128.3 Preparation

128.3.1 Surface Preparation. The surfaces to be brazed shall be clean and free from grease, oxides, paint, scale, dirt, or other material that is detrimental to brazing. A suitable chemical or mechanical cleaning method can be used to provide a clean wettable surface for brazing.

128.3.2 Joint Clearance. The clearance between surfaces to be joined shall be no larger than is necessary to complete capillary distribution of the filler metal.

128.4 Procedure

128.4.1 General

(A) Qualification of the brazing procedures to be used and of the performance of the brazer and brazing operators is required and shall comply with the requirements of para. 128.5.

(B) No brazing shall be done if there is impingement of rain, snow, sleet, or high wind on the area to be brazed.

128.4.2 Heating. The joint shall be brought to brazing temperature in as short a time as possible to minimize oxidation.

128.5 Qualification

128.5.1 General. The qualification of the brazing procedure and of the performance of brazers and brazing operators shall be in accordance with the requirements of Part QB, Section IX, ASME Boiler and Pressure Vessel Code, except as modified herein.

128.5.2 Brazing Responsibility. Each employer (see para. 100.2) shall be responsible for the brazing performed by his organization and the performance of brazers or brazing operators employed by that organization.

128.5.3 Qualification Responsibility

(A) Procedures. Each employer shall be responsible for qualifying any Brazing Procedure Specification

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:36 2005

(BPS) that he intends to have used by personnel of his organization. However, to avoid duplication of effort, and subject to approval of the owner, a BPS qualified by a technically competent group or agency may be used:

(A.1) if the group or agency qualifying the procedures meets all of the procedure qualification requirements of this Code;

(A.2) if the fabricator accepts the procedure thus qualified;

(A.3) if the user of the procedure has qualified at least one brazer using the BPS;

(A.4) if the user of the procedure assumes specific responsibility for the procedure qualification work done by him by signing the records required by para. 128.6.

All four of the above conditions shall be met before a procedure thus qualified may be used.

(B) Brazers and Brazing Operators. Each employer shall be responsible for qualifying all the brazers and brazing operators employed by him.

However, to avoid duplication of effort, he may accept a Brazer/Brazing Operator Performance Qualification (BPQ) made by a previous employer (subject to the approval of the owner or his agent) on piping using the same or an equivalent procedure wherein the essential variables are within the limits established in Section IX, ASME Boiler and Pressure Vessel Code. An employer accepting such qualification tests by a previous employer shall obtain a copy (from the previous employer) of the BPQ, showing the name of the employer by whom the brazers or brazing operators were qualified, the dates of such qualification, and the date the brazer last brazed pressure piping components under such qualification. The employer shall then prepare and sign the record required in para. 128.6 accepting responsibility for the ability of the brazer or brazing operator.

128.6 Brazing Records

The employer shall maintain a record signed by him and available to the purchaser or his agent and the inspector, showing the date and results of procedure and performance qualification.

The BPQ shall also show the identification symbol assigned to the brazer or brazing operator employed by him, and the employer shall use this symbol to identify the brazing performed by the brazer or brazing operator. This may be accomplished by the application of the symbol on the braze joint in a manner specified by the employer. Alternatively, the employer shall maintain records which identify the braze joints(s) made by the brazer or brazing operator.

TABLE 129.3.2
APPROXIMATE LOWER CRITICAL TEMPERATURES

Material	Approximate Lower Critical Temperature (1), °F (°C)
Carbon Steel (P-No. 1)	1340 (725)
Carbon Molybdenum Steel (P-No. 3)	1350 (730)
1Cr–½Mo (P-No 4, Gr. No. 1)	1375 (745)
1¼Cr–½Mo (P-No. 4, Gr. No. 2)	1430 (775)
2¼Cr–1Mo, 3Cr–1Mo (P-No. 5A)	1480 (805)
5Cr–½Mo (P-No. 5B, Gr. No. 1)	1505 (820)
9Cr–½Mo (P-No. 5B, Gr. No. 2)	1490 (810)

NOTE:
(1) These values are intended for guidance only. The user may apply values obtained for the specific material in lieu of these values.

129 BENDING AND FORMING

129.1 Bending

Pipe may be bent by any hot or cold method and to any radius which will result in a bend surface free of cracks, as determined by a method of inspection specified in the design, and substantially free of buckles. Such bends shall meet the design requirements of paras. 102.4.5 and 104.2.1. This shall not prohibit the use of bends designed as creased or corrugated.

129.2 Forming

Piping components may be formed (swedging, lapping, or upsetting of pipe ends, extrusion of necks, etc.) by any suitable hot or cold working method, provided such processes result in formed surfaces which are uniform and free of cracks or other defects, as determined by method of inspection specified in the design.

129.3 Heat Treatment of Bends and Formed Components

129.3.1 Hot bending or forming is performed at a temperature above T_{crit} – 100°F (56°C) where T_{crit} is the lower critical temperature of the material. Cold bending or forming is performed at a temperature below T_{crit} – 100°F (56°C). (See Table 129.3.2 for lower critical temperatures.)

129.3.2 A postbending or postforming heat treatment at the time and temperature cycles listed for postweld heat treatment in Table 132 is required on all carbon steel (P-No. 1) materials with a nominal wall thickness in excess of $\frac{3}{4}$ in. (19.0 mm) unless the bending or forming operations are performed and completed at temperatures of 1650°F (900°C) or greater.

129.3.3 A postforming or postbending heat treatment as defined below is required for all ferritic alloy steel (excluding P-No. 1) materials with a nominal pipe size 4 in. and larger or with a nominal thickness of $\frac{1}{2}$ in. (13.0 mm) or greater.

(A) If hot bending or forming is performed, the material shall receive a full anneal, normalize and temper, or tempering heat treatment as specified by the designer.

(B) If cold bending or forming is performed, a heat treatment is required at the time and temperature cycle listed for the material in Table 132.

129.3.4 Postbending or postforming heat treatment of other materials including austenitic stainless steel is neither required nor prohibited. If a postbending or postforming heat treatment is to be performed, the designer shall fully describe the procedure to be used.

130 REQUIREMENTS FOR FABRICATING AND ATTACHING PIPE SUPPORTS

130.1

Standard pipe hangers and supports shall be fabricated in accordance with the requirements of MSS SP-58. Welders, welding operators, and WPSs shall be qualified in accordance with the requirements of the ASME Boiler and Pressure Vessel Code, Section IX.

130.2

Special hangers, supports, anchors, and guides, not defined as standard types of hanger components in MSS SP-58, shall be welded in accordance with the requirements of para. 127 (Paragraph 132 is not applicable except as required by the weld procedure used.) and inspected in accordance with the requirement of para. 136.4.2.

130.3

Welds attaching hangers, supports, guides, and anchors to the piping system shall conform to the requirements of Chapters V and VI of this Code.

131 WELDING PREHEAT

131.1

The preheat requirements listed herein are mandatory minimum values.

The base metal temperature prior to welding shall be at or above the specified minimum temperature in all directions from the point of welding for a distance of 3 in. or 1.5 times the base metal thickness (as defined in para. 131.4.1), whichever is greater.

The base metal temperature for tack welds shall be at or above the specified minimum temperature for a distance not less than 1 in. in all directions from the point of welding.

131.2

When welding two different P-Number materials, the minimum preheat temperature required shall be the higher temperature for the material to be welded.

131.3

The preheat temperature shall be checked by use of temperature-indicating crayons, thermocouple pyrometers, or other suitable methods to assure that the required preheat temperature is obtained prior to and uniformly maintained during the welding operation.

131.4 Preheat Temperature

The minimum preheat for all materials shall be 50°F (10°C) unless stated otherwise in the following paragraphs.

131.4.1 Thickness referred to is the greater of the nominal thicknesses at the weld of the parts to be joined.

131.4.2 P-No. 1. 175°F (80°C) for material which has both a specified maximum carbon content in excess of 0.30% and a thickness at the joint in excess of 1 in. (25.0 mm). Preheat may be based on the actual carbon content as determined from a ladle or product analysis in accordance with the material specification in lieu of the maximum carbon content specified in the material specification.

131.4.3 P-No. 3. 175°F (80°C) for material or product form which has either a specified minimum tensile strength in excess of 60,000 psi (413.7 MPa) or a thickness at the joint in excess of $\frac{1}{2}$ in. (13.0 mm).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:36 2005

131.4.4 P-No. 4. 250°F (120°C) for all materials.

131.4.5 P-Nos. 5A and 5B

(A) 400°F (200°C) for material which has either a specified minimum tensile strength in excess of 60,000 psi (413.7 MPa), or has both a specified minimum chromium content above 6.0% and a thickness at the joint in excess of $\frac{1}{2}$ in. (13.0 mm);

(B) 300°F (150°C) for all other materials having this P-Number.

131.4.6 P-No. 6. 400°F (200°C) for all materials.

131.4.7 P-Nos. 9A and 9B

(A) 250°F (120°C) for P-No. 9A materials;

(B) 300°F (150°C) for P-No. 9B materials.

131.4.8 P-No. 10I. 300°F (150°C) with an interpass temperature of 450°F (230°C) maximum.

131.5

For inert gas tungsten arc root pass welding, a lower preheat temperature in accordance with the temperature established in the WPS may be used.

131.6 Interruption of Welding

131.6.1 After welding commences, the minimum preheat temperature shall be maintained until any required PWHT is performed on P-Nos. 3, 4, 5A, 5B, and 6, except when all of the following conditions are satisfied.

(A) A minimum of at least $\frac{3}{8}$ in. thickness of weld is deposited or 25% of the welding groove is filled, whichever is less (the weldment shall be sufficiently supported to prevent overstressing the weld if the weldment is to be moved or otherwise loaded).

(B) For P-Nos. 3, 4, and 5A (with a chromium content of 3.0% maximum) materials, the weld is allowed to cool slowly to room temperature.

(C) For P-No. 5B (with a chromium content greater than 3.0%) and P-No. 6 materials, the weld is subjected to an adequate intermediate heat treatment with a controlled rate of cooling.

(D) After cooling and before welding is resumed, visual examination of the weld shall be performed to assure that no cracks have formed.

(E) Required preheat shall be applied before welding is resumed.

132 POSTWELD HEAT TREATMENT

132.1

Before applying the detailed requirements and exemptions in these paragraphs, satisfactory qualification of the WPS to be used shall be performed in accordance with the essential variables of the ASME Boiler and Pressure Vessel Code, Section IX including the conditions of postweld heat treatment or lack of postweld heat treatment and including other restrictions listed below. Except as otherwise provided in paras. 132.2 and 132.3, all welds in materials included in the P-Numbers listed in Table 132 shall be given a postweld heat treatment within the temperature range specified in Table 132. (The range specified in Table 132 may be modified by Table 132.1 for the lower limit and para. 132.2 for the upper limit.) The materials in Table 132 are listed in accordance with the material P-Number grouping of Appendix A. Welds of materials not included in Table 132 shall be heat treated in accordance with the WPS.

132.2

Heat treatment may be accomplished by a suitable heating method which will provide the desired heating and cooling rates, the required metal temperature, temperature uniformity, and temperature control.

(A) The upper limit of the PWHT temperature range in Table 132 is a recommended value which may be exceeded provided the actual temperature does not exceed the lower critical temperature of either material (see Table 129.3.2).

(B) When parts of two different P-Numbers are joined by welding, the postweld heat treatment shall be that specified for the material requiring the higher PWHT temperature. When a nonpressure part is welded to a pressure part and PWHT is required for either part, the maximum PWHT temperature shall not exceed the maximum temperature acceptable for the pressure retaining part.

(C) Caution is necessary to preclude metallurgical damage to some materials or welds not intended or qualified to withstand the PWHT temperatures required.

TABLE 132
POSTWELD HEAT TREATMENT

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 1 Gr. Nos. 1, 2, 3	1100 (600) to 1200 (650)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTES:
(A) PWHT of P-No. 1 materials is not mandatory, provided that all of the following conditions are met:
(1) the nominal thickness, as defined in para. 132.4.1, is $\frac{3}{4}$ in. (19.0 mm) or less;
(2) a minimum preheat of 200°F (95°C) is applied when the nominal material thickness of either of the base metals exceeds 1 in. (25.0 mm).
(B) When it is impractical to PWHT at the temperature range specified in Table 132, it is permissible to perform the PWHT of this material at lower temperatures for longer periods of time in accordance with Table 132.1.

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 3 Gr. Nos. 1, 2	1100 (600) to 1200 (650)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTES:
(A) PWHT of P-No. 3 materials is not mandatory, provided all of the following conditions are met:
(1) the nominal thickness, as defined in para. 132.4.1, is $\frac{5}{8}$ in. (16.0 mm) or less;
(2) a minimum preheat of 200°F (95°C) is applied when the nominal material thickness of either of the base metals exceeds $\frac{5}{8}$ in. (16.0 mm);
(3) the specified carbon content of the P-No. 3 base material is 0.25% or less.
(B) When it is impractical to PWHT at the temperature range specified in Table 132, it is permissible to perform the PWHT of this material at lower temperatures for longer periods of time in accordance with Table 132.1.

132.3 Exemptions to Mandatory PWHT Requirements

132.3.1 Postweld heat treatment is not required for the following conditions:

(A) welds in nonferrous materials;

(B) welds exempted in Table 132;

(C) welds subject to temperatures above the lower critical temperature (see Table 129.3.2) during fabrication provided the WPS has been qualified with PWHT (see para. 132.1) at the temperature range to be reached during fabrication.

132.3.2 The postweld heat treatment exemption of Table 132 may be based on the actual chemical composition as determined by a ladle or product analysis in accordance with the material specification in lieu of the specified or maximum specified chemical composition limits.

132.4 Definition of Thickness Governing PWHT

132.4.1 The term *nominal thickness* as used in Table 132 and Notes is the lesser thickness of (A) or (B) as follows:

(A) the thickness of the weld;

(B) the thicker of the materials being joined at the weld.

132.4.2 Thickness of the weld, which is a factor in determining the nominal thickness, is defined as follows:

(A) groove welds (girth and longitudinal)—the thicker of the two abutting ends after weld preparation, including I.D. machining;

(B) fillet welds—the throat thickness of the weld;

(C) partial penetration welds—the depth of the weld groove;

TABLE 132
POSTWELD HEAT TREATMENT (CONT'D)

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 4 Gr. Nos. 1, 2	1300 (700) to 1375 (750)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTE:
(A) PWHT is not mandatory for P-No. 4 material under the following conditions:
- (1) welds in pipe or attachment welds to pipe complying with all of the following conditions:
  - (A) a nominal material thickness of $\frac{1}{2}$ in. (13.0 mm) or less;
  - (B) a specified carbon content of the material to be welded of 0.15% or less;
  - (C) application of 250°F (120°C) minimum preheat during welding.
- (2) for seal welding of threaded or other mechanical joints provided:
  - (A) the seal weld has a throat thickness of $\frac{3}{8}$ in. (9.0 mm) or less;
  - (B) a minimum preheat of 250°F (120°C) is maintained during welding.
- (3) Attachment welds for non-load-carrying attachments provided in addition to (A)(2) and (A)(3) above:
  - (A) stud welds or fillet welds made by the SMAW or GTAW process shall be used;
  - (B) the hardened portion of the heat affected zone (HAZ) shall not encroach on the minimum wall thickness of the pipe, as determined by welding procedure qualification using the maximum welding heat input. The depth of the HAZ shall be taken as the point where the HAZ hardness does not exceed the average unaffected base metal hardness by more than 10%.
  - (C) if SMAW is used, the electrode shall be the low hydrogen type;
  - (D) the thickness of the test plate used in making the welding procedure qualification of Section IX shall not be less than that of the material to be welded;
  - (E) the attachment weld has a throat thickness of $\frac{3}{16}$ in. or less.

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 5A Gr. No. 1	1300 (700) to 1400 (760)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTE:
(A) PWHT is not mandatory for P-No. 5A material under the following conditions:
- (1) welds in pipe or attachment welds to pipe complying with all of the following conditions:
  - (A) a nominal material thickness of $\frac{1}{2}$ in. (13.0 mm) or less;
  - (B) a specified carbon content of the material to be welded of 0.15% or less;
  - (C) a minimum preheat of 300°F (150°C) is maintained during welding.
- (2) attachment welds for non-load-carrying attachments provided in addition to (A)(2) and (A)(3) above:
  - (A) stud welds or fillet welds made by the SMAW or GTAW process shall be used;
  - (B) the hardened portion of the heat affected zone (HAZ) shall not encroach on the minimum wall thickness of the pipe, as determined by welding procedure qualification using the maximum welding heat input. The depth of the HAZ shall be taken as the point where the HAZ hardness does not exceed the average unaffected base metal hardness by more than 10%.
  - (C) if SMAW is used, the electrode shall be the low hydrogen type;
  - (D) the thickness of the test plate used in making the welding procedure qualification of Section IX shall not be less than that of the material to be welded;
  - (E) the attachment weld has a throat thickness of $\frac{3}{16}$ in. or less.

TABLE 132
POSTWELD HEAT TREATMENT (CONT'D)

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 5B Gr. Nos. 1, 2	1300 (700) to 1400 (760)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 6 Gr. Nos. 1, 2, 3	1400 (760) to 1475 (800)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTE:
(A) PWHT is not mandatory for P-No. 6 Type 410 material provided all of the following conditions are met:
(1) the specified carbon content is not more than 0.08%;
(2) the nominal material thickness is $\frac{3}{8}$ in. (10 mm) or less;
(3) the weld is made with A-No. 8, A-No. 9, or F-No. 43 filler metal.

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 7 Gr. Nos. 1, 2	1350 (730) to 1425 (775)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTES:
(A) In lieu of the cooling rate described in para. 132.5, P-No. 7 material cooling rate shall be not greater than 100°F (55°C) per hr in the range above 1200°F (650°C) after which the cooling rate shall be sufficiently rapid to prevent embrittlement.
(B) PWHT is not mandatory for P-No. 7 Type 405 material provided all of the following conditions are met:
(1) the specified carbon content is not more than 0.08%;
(2) the nominal material thickness is $\frac{3}{8}$ in. (10 mm) or less;
(3) the weld is made with A-No. 8, A-No. 9, or F-No. 43 filler metal.

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 8 Gr. Nos. 1, 2, 3, 4	None	None	None

GENERAL NOTE:
(A) PWHT is neither required nor prohibited for joints between P-No. 8 austenitic stainless steels.

TABLE 132
POSTWELD HEAT TREATMENT (CONT'D)

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 9A Gr. No. 1	1100 (600) to 1200 (650)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTES:

(A) PWHT is not mandatory for P-No. 9A material when welds on pipe or attachment welds to pipe comply with all of the following conditions:
(1) a nominal material thickness of ½ in. (13.0 mm) or less;
(2) a specified carbon content of the material to be welded of 0.15% or less;
(3) a minimum preheat of 250°F (120°C) is maintained during welding.

(B) When it is impractical to PWHT at the temperature range specified in Table 132, it is permissible to perform the PWHT of this material at lower temperatures for longer periods of time in accordance with Table 132.1 but the minimum PWHT shall not be less than 1000°F (550°C).

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 9B Gr. No. 1	1100 (600) to 1175 (630)	1 hr/in. (25 mm) 15 min minimum	2 hr plus 15 min for each additional inch over 2 in. (50 mm)

GENERAL NOTES:

(A) PWHT of P-No. 9B material is not mandatory for a nominal material thickness of ⅝ in. (16.0 mm) or less provided the Welding Procedure Qualification has been made using material of thickness equal to or greater than the production weld.

(B) When it is impractical to PWHT at the temperature range specified in Table 132, it is permissible to perform the PWHT of this material at lower temperatures for longer periods of time in accordance with Table 132.1, but the minimum PWHT temperature shall not be less than 1000°F (550°C).

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 10H Gr. No. 1	...	...	...

GENERAL NOTE:

(A) Postweld heat treatment is neither required nor prohibited. If any heat treatment is performed after forming or welding, it shall be performed within the temperature range listed below for the particular alloy, followed by a rapid cool:

Alloy S31803	1870°F–2010°F
Alloy S32550	1900°F–2050°F
Alloy S32750	1880°F–2060°F
All others	1800°F–1900°F

01

TABLE 132
POSTWELD HEAT TREATMENT (CONT'D)

P-Number from Appendix A	Holding Temperature Range, °F (°C)	Holding Time Based on Nominal Thickness	
		Up to 2 in. (50 mm)	Over 2 in. (50 mm)
P-No. 10I Gr. No. 1	1350 (730) to 1500 (815)	1 hr/in. (25 mm) 15 min minimum	1 hr/in. (25 mm)

GENERAL NOTES:
(A) In lieu of the cooling rate described in para. 132.5, the P-No. 10 I material cooling rate shall be not greater than 100°F/hr in the range above 1200°F (650°C), after which the cooling rate shall be sufficiently rapid to prevent embrittlement.
(B) Postweld heat treatment is neither required nor prohibited for a nominal thickness of ½ in. or less.

(D) material repair welds—the depth of the cavity to be repaired;

(E) branch welds—the weld thickness is the dimension existing in the plane intersecting the longitudinal axes and is calculated as indicated for each detail using:

t_c = the smaller of ¼ in. or $0.7t_{nb}$

(1) for welds described in Fig. 127.4.8(D):

Detail (a)

$$\text{weld thickness} = t_{nb} + t_c$$

Detail (b)

$$\text{weld thickness} = t_{nh} + t_c$$

Detail (c)

$$\text{weld thickness} = \text{greater of } t_{nr} + t_c \text{ or } t_{nb} + t_c$$

Detail (d)

$$\text{weld thickness} = t_{nh} + t_{nr} + t_c$$

Detail (e)

$$\text{weld thickness} = t_{nb} + t_c$$

(2) for welds described in Figs. 127.4.8(E) and (F):

$$\text{weld thickness} = \text{depth of groove weld} + \text{throat thickness of cover fillet}$$

132.4.3 The term *nominal material thickness* as used in Table 132 is the thicker of the materials being joined at the weld.

132.5 PWHT Heating and Cooling Requirements

Above 600°F (315°C), the rate of heating and cooling shall not exceed 600°F (335°C) per hr divided by ½ the maximum thickness of material in inches at the weld but in no case shall the rate exceed 600°F (335°C) per hr. (See Table 132 for cooling rate requirements for P-Nos. 7 and 10I materials.)

132.6 Furnace Heating

(A) Heating an assembly in a furnace should be used when practical; however, the size or shape of the unit or the adverse effect of a desired heat treatment on one or more components where dissimilar materials are involved, may dictate alternative procedures such as heating a section before assembly, or by applying local heating in accordance with para. 132.7.

(B) An assembly may be postweld heat treated in more than one heat in a furnace provided there is at least a 1 ft (300 mm) overlap of the heated sections and the portion of the assembly outside the furnace is shielded so that the temperature gradient is not harmful.

(C) Direct impingement of flame on the assembly is prohibited.

132.7 Local Heating

Welds may be locally PWHT by heating a circumferential band around the entire component with the weld located in the center of the band. The width of the band heated to the PWHT temperature for girth welds shall be at least three times the wall thickness at the weld of the thickest part being joined. For nozzle and attachment welds, the width of the band heated to the PWHT temperature shall extend beyond the nozzle weld or attachment weld on each side at least two

TABLE 132.1
ALTERNATE POSTWELD HEAT TREATMENT REQUIREMENTS FOR CARBON AND LOW ALLOY STEELS

Decrease in Temperatures Below Minimum Specified Temperature, °F (°C)	Minimum Holding Time at Decreased Temperature, hr [Note (2)]
50 (28)	2
100 (56)	4
150 (84) [Note (1)]	10
200 (112) [Note (1)]	20

GENERAL NOTE:
Postweld heat treatment at lower temperatures for longer periods of time, in accordance with this Table, shall be used only where permitted in Table 132.

NOTES:
(1) A decrease of more than 100°F (56°C) below the minimum specified temperature is allowable only for P-No. 1, Gr. Nos. 1 and 2 materials.
(2) Times shown apply to thicknesses up to 1 in. (25 mm). Add 15 min/in. (15 min/25 mm) of thicknesses for thicknesses greater than 1 in. (25 mm).

times the header thickness and shall extend completely around the header.

133 STAMPING

Stamping, if used, shall be performed by a method that will not result in sharp discontinuities. In no case shall stamping infringe on the minimum wall thickness or result in dimpling or denting of the material being stamped.

CAUTIONARY NOTE: Detrimental effects can result from stamping of material which will be in operation under long term creep or creep fatigue conditions.

135 ASSEMBLY

135.1 General

The assembly of the various piping components, whether done in a shop or as field erection, shall be done so that the completely erected piping conforms with the requirements of the engineering design.

135.2 Alignment

135.2.1 Equipment Connections. When making connections to equipment, such as pumps or turbines or other piping components which are sensitive to externally induced loading, forcing the piping into alignment is prohibited if this action introduces end reactions which exceed those permitted by design.

135.2.2 Cold Springs. Before assembling joints in piping to be cold sprung, an examination shall be made of guides, supports, and anchors for obstructions which might interfere with the desired movement or result in undesired movement. The gap or overlap of piping prior to assembly shall be checked against the design specifications and corrected if necessary.

135.3 Bolted Flanged Connections

135.3.1 Fit Up. All flanged joints shall be fitted up so that the gasket contact surfaces bear uniformly on the gasket and then shall be made up with relatively uniform bolt stress.

135.3.2 Gasket Compression. When bolting gasketed flange joints, the gasket shall be properly compressed in accordance with the design principles applicable to the type of gasket being used.

135.3.3 Cast Iron to Steel Joints. Cast iron to steel flanged joints in accordance with para 108.3 shall be assembled with care to prevent damage to the cast iron flange.

135.3.4 Bolt Engagement. All bolts shall be engaged so that there is visible evidence of complete threading through the nut or threaded attachment.

135.3.5 Nonmetallic Lined Joints. When assembling nonmetallic lined joints, such as plastic lined steel pipe, consideration should be given to maintaining electrical continuity between flanged pipe sections where required.

135.4 Packed Joints and Caulked Joints

Care shall be used to assure adequate engagement of joint members. Where packed joints are used to absorb thermal expansion, proper clearance shall be provided at the bottom of the sockets to permit movement.

135.5 Threaded Piping

135.5.1 Thread Compound. Any compound or lubricant used in threaded joints shall be suitable for the service conditions, and shall be compatible with the piping material and the service fluid.

Copyright by the American Society Of Mechanical Engineers

GENERAL NOTE: Threads are ASME B1.1 straight threads.

FIG. 135.5.3 TYPICAL THREADED JOINTS USING STRAIGHT THREADS

135.5.2 Joints for Seal Welding. Threaded joints which are intended to be seal welded in accordance with para. 127.4.5 *should* be made up without any thread compound.

135.5.3 Joints Using Straight Threads. Some joints using straight threads, with sealing at a surface other than threads, are shown in Fig. 135.5.3. Care shall be used to avoid distorting the seal when incorporating such joints into piping assemblies by welding or brazing.

135.5.4 Backing Off. Backing off threaded joints to allow for alignment is prohibited.

135.6 Tubing Joints

135.6.1 Flared. The sealing surface shall be free of injurious defects before installation.

135.6.2 Flareless and Compression. Flareless and compression joints shall be assembled in accordance with manufacturer's recommendations.

CHAPTER VI
INSPECTION, EXAMINATION, AND TESTING

136 INSPECTION AND EXAMINATION

136.1 Inspection

136.1.1 General. This Code distinguishes between "examination" and "inspection." Inspection is the responsibility of the Owner and may be performed by employees of the Owner or a party authorized by the Owner, except for the inspections required by para. 136.2. Prior to initial operation, a piping installation shall be inspected to assure compliance with the engineering design and with the material, fabrication, assembly, examination, and test requirements of this Code.

136.1.2 Verification of Compliance. Compliance with the requirements of this Code shall be verified by an Authorized Inspector when a Code stamp is required by Section I of the ASME Boiler and Pressure Vessel Code. The rules of this Code and the quality control system requirements of Appendix A-300 of Section I of the ASME Boiler and Pressure Vessel Code shall apply. The quality control system requirments are shown in Appendix J of this Code. The duty of the Inspector shall be as defined in PG-90, Section I, of the ASME Boiler and Pressure Vessel Code. Data Report Forms are included in the Appendix of ASME Section I for use in developing the necessary inspection records. The Inspector shall assure himself/herself that the piping has been constructed in accordance with the applicable requirements of this Code.

136.1.3 Rights of Inspectors. Inspectors shall have access to any place where work concerned with the piping is being performed. This includes manufacture, fabrication, heat treatment, assembly, erection, examination, and testing of the piping. They shall have the right to audit any examination, to inspect the piping using any appropriate examination method required by the engineering design or this Code, and to review all certifications and records necessary to satisfy the Owner's responsibility as stated in para. 136.1.1.

136.1.4 Qualifications of the Owner's Inspector

(A) The Owner's Inspector shall be designated by the Owner and shall be an employee of the Owner, an employee of an engineering or scientific organization, or of a recognized insurance or inspection company acting as the Owner's agent. The Owner's Inspector shall not represent nor be an employee of the piping manufacturer, fabricator, or erector unless the Owner is also the manufacturer, fabricator, or erector.

(B) The Owner's Inspector shall have not less than 10 years experience in the design, manufacture, erection, fabrication, or inspection of power piping. Each year of satisfactorily completed work toward an engineering degree recognized by the Accreditation Board for Engineering and Technology shall be considered equivalent to 1 year of experience, up to 5 years total.

(C) In delegating the performance of inspections, the Owner is responsible for determining that a person to whom an inspection function is delegated is qualified to perform that function.

136.2 Inspection and Qualification of Authorized Inspector for Boiler External Piping

136.2.1 Piping for which inspection and stamping is required as determined in accordance with para. 100.1.2(A) shall be inspected during construction and after completion and at the option of the Authorized Inspector at such stages of the work as he/she may designate. For specific requirements see the applicable parts of Section I of the ASME Boiler and Pressure Vessel Code, PG-104 through PG-113. Each manufacturer, fabricator, or assembler is required to arrange for the services of Authorized Inspectors.

136.2.1.1 The inspections required by this Section shall be performed by an Inspector employed by an ASME accredited Authorized Inspection Agency.

136.2.2 Certification by stamping and Data Reports, where required, shall be as per PG-104, PG-105, PG-109, PG-110, PG-111, and PG-112 of Section I of the ASME Boiler and Pressure Vessel Code.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:40 2005

136.3 Examination

136.3.1 General. Examination denotes the functions performed by the manufacturer, fabricator, erector, or a party authorized by the Owner which include nondestructive examinations (NDE), such as visual, radiography, ultrasonic, eddy current, liquid penetrant, and magnetic particle methods. The degree of examination and the acceptance standards beyond the requirements of this Code shall be a matter of prior agreement between the manufacturer, fabricator, or erector and the Owner.

136.3.2 Qualification of NDE Personnel. Personnel who perform nondestructive examination of welds shall be qualified and certified for each examination method in accordance with a program established by the employer of the personnel being certified, which shall be based on the following minimum requirements:

(A) instruction in the fundamentals of the nondestructive examination method;

(B) on-the-job training to familiarize the NDE personnel with the appearance and interpretation of indications of weld defects. The length of time for such training shall be sufficient to assure adequate assimilation of the knowledge required;

(C) an eye examination performed at least once each year to determine optical capability of NDE personnel to perform the required examinations;

(D) upon completion of (A) and (B) above, the NDE personnel shall be given an oral or written examination and performance examination by the employer to determine if the NDE personnel are qualified to perform the required examinations and interpretation of results;

(E) certified NDE personnel whose work has not included performance of a specific examination method for a period of 1 year or more shall be recertified by successfully completing the examination of (D) above and also passing the visual examination of (C) above. Substantial changes in procedures or equipment shall require recertification of the NDE personnel.

The following may be used as alternatives to the preceding program, as applicable: SNT-TC-1A or CP-189; and personnel qualified to AWS QC-1 may be used for the visual examination of welds.

136.4 Examination Methods of Welds

136.4.1 Nondestructive Examination. Nondestructive examinations shall be performed in accordance with the requirements of this Chapter. The types and extent of mandatory examinations for pressure welds and welds to pressure retaining components are specified in Table 136.4. For welds other than those covered by Table 136.4, only visual examination is required. Welds requiring nondestructive examination shall comply with the applicable acceptance standards for indications as specified in paras. 136.4.2 through 136.4.6. As a guide, the detection capabilities for the examination method are shown in Table 136.4.1. Welds not requiring examination (i.e., RT, UT, MT, or PT) by this Code or the engineering design shall be judged acceptable if they meet the examination requirements of para. 136.4.2 and the pressure test requirements specified in para. 137.

136.4.2 Visual Examination. Visual examination as defined in para. 100.2. shall be performed, as necessary, during the fabrication and erection of piping components to provide verification that the design and WPS requirements are being met. In addition, visual examination shall be performed to verify that all completed welds in pipe and piping components comply with the acceptance standards specified in (A) below or with the limitations on imperfections specified in the material specification under which the pipe or component was furnished.

(A) Acceptance Standards. The following indications are unacceptable:

(A.1) cracks—external surface;

(A.2) undercut on surface which is greater than $^1/_{32}$ in. (1.0 mm) deep;

(A.3) weld reinforcement greater than specified in Table 127.4.2;

(A.4) lack of fusion on surface;

(A.5) incomplete penetration (applies only when inside surface is readily accessible);

(A.6) any other linear indications greater than $^3/_{16}$ in. (5.0 mm) long;

(A.7) surface porosity with rounded indications having dimensions greater than $^3/_{16}$ in. (5.0 mm) or four or more rounded indications separated by $^1/_{16}$ in. (2.0 mm) or less edge to edge in any direction. Rounded indications are indications which are circular or elliptical with their length less than three times their width.

136.4.3 Magnetic Particle Examination. Whenever required by this Chapter (see Table 136.4), magnetic particle examination shall be performed in accordance with the methods of Article 7, Section V, of the ASME Boiler and Pressure Vessel Code.

(A) Evaluation of Indications

(A.1) Mechanical discontinuities at the surface will be indicated by the retention of the examination medium. All indications are not necessarily defects; however,

TABLE 136.4
MANDATORY MINIMUM NONDESTRUCTIVE EXAMINATIONS FOR PRESSURE WELDS OR WELDS TO PRESSURE RETAINING COMPONENTS

	Piping Design Conditions and Nondestructive Examination		
Type Weld	Temperatures Over 750°F (400°C) and at All Pressures	Temperatures Between 350°F (175°C) and 750°F (400°C) Inclusive With All Pressures Over 1025 psig [7100 kPa (gage)]	All Others
Butt welds (girth and longitudinal) [Note (1)]	RT or UT for over NPS 2. MT or PT for NPS 2 and less [Note (2)]	RT or UT for over NPS 2 with thickness over 3/4 in. (19.0 mm). VT for all sizes with thickness 3/4 in. (19.0 mm) or less.	Visual for all sizes and thicknesses
Welded branch connections (size indicated is branch size) [Notes (3) and (4)]	RT or UT for over NPS 4. MT or PT for NPS 4 and less [Note (2)]	RT or UT for branch over NPS 4 and thickness of branch over 3/4 in. (19.0 mm) MT or PT for branch NPS 4 and less with thickness of branch over 3/4 in. (19 mm) VT for all sizes with branch thickness 3/4 in. (19.0 mm) or less	VT for all sizes and thicknesses
Fillet, socket, attachment, and seal welds	PT or MT for all sizes and thicknesses [Note (5)]	VT for all sizes and thicknesses	VT for all sizes and thicknesses

GENERAL NOTES:

(A) All welds shall be given a visual examination in addition to the type of specific nondestructive examination specified.

(B) NPS — nominal pipe size.

(C) RT — radiographic examination; UT — ultrasonic examination; MT — magnetic particle examination; PT — liquid penetrant examination; VT — visual examination.

(D) For nondestructive examinations of the pressure retaining component, refer to the standards listed in Table 126.1 or manufacturing specifications.

(E) Acceptance standards for nondestructive examinations performed are as follows: MT — see para. 136.4.3; PT — see para. 136.4.4; VT — see para. 136.4.2; RT — see para. 136.4.5; UT — see para. 136.4.6.

NOTES:

(1) The thickness of butt welds is defined as the thicker of the two abutting ends after end preparation.

(2) RT may be used as an alternative to PT or MT when it is performed in accordance with para. 136.4.5.

(3) RT or UT of branch welds shall be performed before any nonintegral reinforcing material is applied.

(4) In lieu of volumetric examination (RT, UT) of welded branch connections when required above, surface examination (PT, MT) is acceptable and, when used, shall be performed at the lesser of one-half of the weld thickness or each 1/2 in. (12.5 mm) of weld thickness and all accessible final weld surfaces.

(5) Fillet welds not exceeding 1/4 in. (6 mm) throat thickness which are used for the permanent attachment of nonpressure retaining parts are exempt from the PT or MT requirements of the above Table.

TABLE 136.4.1
WELD IMPERFECTIONS INDICATED BY VARIOUS TYPES OF EXAMINATION

Imperfection	Visual	Magnetic Particle	Liquid Penetrant	Radiography	Ultrasonic
Crack — surface	X [Note (1)]	X [Note (1)]	X [Note (1)]	X	X
Crack — internal	...	...	...	X	X
Undercut — surface	X [Note (1)]	X [Note (1)]	X [Note (1)]	X	...
Weld reinforcement	X [Note (1)]	...	...	X	...
Porosity	X [Notes (1), (2)]	X [Notes (1), (2)]	X [Notes (1), (2)]	X	...
Slag inclusion	X [Note (2)]	X [Note (2)]	X [Note (2)]	X	X
Lack of fusion (on surface)	X [Notes (1), (2)]	X [Notes (1), (2)]	X [Notes (1), (2)]	X	X
Incomplete penetration	X [Note (3)]	X [Note (3)]	X [Note (3)]	X	X

NOTES:
(1) Applies when the outside surface is accessible for examination and/or when the inside surface is readily accessible.
(2) Discontinuities are detectable when they are open to the surface.
(3) Applies *only* when the inside surface is readily accessible.

certain metallurgical discontinuities and magnetic permeability variations may produce similar indications which are not relevant to the detection of unacceptable discontinuities.

(A.2) Any indication which is believed to be nonrelevant shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications which would mask indications of defects are unacceptable.

(A.3) Relevant indications are those which result from unacceptable mechanical discontinuities. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length less than three times the width.

(A.4) An indication of a discontinuity may be larger than the discontinuity that causes it; however, the size of the indication and not the size of the discontinuity is the basis of acceptance or rejection.

(B) Acceptance Standards. The following relevant indications are unacceptable:

(B.1) any cracks or linear indications;

(B.2) rounded indications with dimensions greater than $^3/_{16}$ in. (5.0 mm);

(B.3) four or more rounded indications in a line separated by $^1/_{16}$ in. (2.0 mm) or less edge to edge;

(B.4) Ten or more rounded indications in any 6 sq in. (3870 mm^2) of surface with the major dimension of this area not to exceed 6 in. (150 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

136.4.4 Liquid Penetrant Examination. Whenever required by this Chapter (see Table 136.4), liquid penetrant examination shall be performed in accordance with the methods of Article 6, Section V, of the ASME Boiler and Pressure Vessel Code.

(A) Evaluation of Indications

(A.1) Mechanical discontinuities at the surface will be indicated by bleeding out of the penetrant; however, localized surface imperfections, such as may occur from machining marks or surface conditions, may produce similar indications which are nonrelevant to the detection of unacceptable discontinuities.

(A.2) Any indication which is believed to be nonrelevant shall be regarded as a defect and shall be reexamined to verify whether or not actual defects are present. Surface conditioning may precede the reexamination. Nonrelevant indications and broad areas of pigmentation which would mask indications of defects are unacceptable.

(A.3) Relevant indications are those which result from mechanical discontinuities. Linear indications are those indications in which the length is more than three times the width. Rounded indications are indications which are circular or elliptical with the length less than three times the width.

(A.4) An indication of a discontinuity may be larger

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:41 2005

than the discontinuity that causes it; however, the size of the indication and not the size of the discontinuity is the basis of acceptance or rejection.

(B) Acceptance Standards. Indications whose major dimensions are greater than $^1/_{16}$ in. (2.0 mm) shall be considered relevant. The following relevant indications are unacceptable:

(B.1) any cracks or linear indications;

(B.2) rounded indications with dimensions greater than $^3/_{16}$ in. (5.0 mm);

(B.3) four or more rounded indications in a line separated by $^1/_{16}$ in. (2.0 mm) or less edge to edge;

(B.4) ten or more rounded indications in any 6 sq in. (3870 mm^2) of surface with the major dimension of this area not to exceed 6 in. (150 mm) with the area taken in the most unfavorable location relative to the indications being evaluated.

136.4.5 Radiography. When required by this Chapter (see Table 136.4), radiographic examination shall be performed in accordance with Article 2 of Section V of the ASME Boiler and Pressure Vessel Code, except that the requirements of T-285 are to be used as a guide but not for the rejection of radiographs unless the geometrical unsharpness exceeds 0.07 in. (2.0 mm).

(A) Acceptance Standards. Welds that are shown by radiography to have any of the following types of discontinuities are unacceptable:

(A.1) any type of crack or zone of incomplete fusion or penetration;

(A.2) any other elongated indication which has a length greater than:

(A.2.1) $^1/_4$ in. (6.0 mm) for t up to $^3/_4$ in. (19.0 mm), inclusive;

(A.2.2) $^1/_3t$ for t from $^3/_4$ in. (19.0 mm) to $2^1/_4$ in. (57.0 mm), incl.;

(A.2.3) $^3/_4$ in. (19.0 mm) for t over $2^1/_4$ in. (57.0 mm) where t is the thickness of the thinner portion of the weld.

NOTE: t referred to in (A.2.1), (A.2.2), and (A.2.3) above pertains to the thickness of the weld being examined; if a weld joins two members having different thickness at the weld, t is the thinner of these two thickness.

(A.3) any group of indications in line that have an aggregate length greater than t in a length of $12t$, except where the distance between the successive indications exceeds $6L$ where L is the longest indication in the group;

(A.4) porosity in excess of that shown as acceptable in Appendix A-250 of Section I of the ASME Boiler and Pressure Vessel Code;

(A.5) root concavity when there is an abrupt change in density, as indicated on the radiograph.

136.4.6 Ultrasonic Examination. When required by this Chapter (see Table 136.4), ultrasonic examination (UT) shall be performed in accordance with the ASME Boiler and Pressure Vessel Code, Section V, Article 5 and the following additional requirements.

(A) The following criteria shall also be met when performing ultrasonic examinations.

(A.1) The nominal thickness of the material being examined shall be greater that $^1/_2$ in (12.5 mm).

(A.2) The equipment used to perform the examination shall be capable of recording the UT data including the scanning positions.

(A.3) NDE personnel collecting and analyzing UT data shall have demonstrated their ability to perform an acceptable examination using written procedures. The procedure shall have been demonstrated to perform acceptably on a qualification block with imbedded flaws.

(B) Acceptance Standards. Welds that are shown by ultrasonic examination to have discontinuities which produce an indication greater than 20% of the reference level shall be investigated to the extent that ultrasonic examination personnel can determine their shape, identity, and location so that they may evaluate each discontinuity for acceptance in accordance with (B.1) and (B.2) below.

(B.1) Discontinuities evaluated as being cracks, lack of fusion, or incomplete penetration are unacceptable regardless of length.

(B.2) Other discontinuities are unacceptable if the indication exceeds the reference level and their length exceeds the following:

(B.2.1) $^1/_4$ in. (6.0 mm) for t up to $^3/_4$ in. (19.0 mm);

(B.2.2) $^1/_3t$ for t from $^3/_4$ in. (19.0 mm) to $2^1/_4$ in. (57.0 mm)

(B.2.3) $^3/_4$ in. (19.0 mm) for t over $2^1/_4$ in. (57.0 mm) where t is the thickness of the weld being examined. If the weld joins two members having different thicknesses at the weld, t is the thinner of these two thicknesses.

137 PRESSURE TESTS

137.1 General Requirements

137.1.1 Subassemblies. When conducted in accordance with the requirements of this Code, the pressure testing of piping systems to ensure leak tightness shall

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:42 2005

be acceptable for the determination of any leaks in piping subassemblies.

137.1.2 Temperature of Test Medium. The temperature of the test medium shall be that of the available source unless otherwise specified by the Owner. The test pressure shall not be applied until the system and the pressurizing medium are approximately at the same temperature. When conducting pressure tests at low metal temperatures, the possibility of brittle fracture shall be considered.

137.1.3 Personnel Protection. Suitable precautions in the event of piping system rupture shall be taken to eliminate hazards to personnel in the proximity of lines being tested.

137.1.4 Maximum Stress During Test. At no time during the pressure test shall any part of the piping system be subjected to a stress greater than that permitted by para. 102.3.3(B).

137.1.5 Testing Schedule. Pressure testing shall be performed following the completion of postweld heat treatment, required by para. 132, nondestructive examinations required by Table 136.4, and all other fabrication, assembly and erection activities required to provide the system or portions thereof subjected to the pressure test with pressure retaining capability.

137.2 Preparation for Testing

137.2.1 Exposure of Joints. All joints including welds not previously pressure tested shall be left uninsulated and exposed for examination during the test. By prior agreement the complete system or portions thereof subject to test may be insulated prior to the test period provided an extended holding time pressurization of the system is performed to check for possible leakage through the insulation barrier.

137.2.2 Addition of Temporary Supports. Piping systems designed for vapor or gas shall be provided with additional temporary supports if necessary to support the weight of the test liquid. Such supports shall meet the requirements for testing and system cleanup procedures described in para. 122.10.

137.2.3 Restraint or Isolation of Expansion Joints. Expansion joints shall be provided with temporary restraint if required for the additional pressure load under test, or they shall be isolated during the system test.

137.2.4 Isolation of Equipment and Piping Not Subjected to Pressure Test. Equipment that is not to be subjected to the pressure test shall be either disconnected from the system or isolated by a blank or similar means. Valves may be used for this purpose provided that valve closure is suitable for the proposed test pressure. Owner shall be aware of the limitations of pressure and temperature for each valve subject to test conditions and as further described in para. 107.1(C). Isolated equipment and piping must be vented.

137.2.5 Treatment of Flanged Joints Containing Blanks. Flanged joints at which blanks are inserted to blank off other equipment during the test need not be tested after removal of the blank provided the requirements of para. 137.7.1 are subsequently performed.

137.2.6 Precautions Against Test Medium Expansion. If a pressure test is to be maintained for a period of time during which the test medium in the system is subject to thermal expansion, precautions shall be taken to avoid excessive pressure. A pressure relief device set at $1\frac{1}{3}$ times the test pressure is recommended during the pressure test provided the requirements of paras. 137.1.4, 137.4.5, and 137.5.5 are not exceeded.

137.3 Requirements for Specific Piping Systems

137.3.1 Boiler External Piping. Boiler external piping [see para. 100.1.2(A)] shall be hydrostatically tested in accordance with PG-99 of Section I of the ASME Boiler and Pressure Vessel Code. The test shall be conducted in the presence of the Authorized Inspector.

137.3.2 Nonboiler External Piping. All nonboiler external piping shall be hydrostatically tested in accordance with para. 137.4. As an alternative, when specified by the owner, the piping may be leak tested in accordance with para. 137.5, 137.6, or 137.7. Lines open to the atmosphere, such as vents or drains downstream of the last shutoff valve, need not be tested.

137.4 Hydrostatic Testing

137.4.1 Material. When permitted by the Material Specification, a system hydrostatic test may be performed in lieu of the hydrostatic test required by the material specifications for material used in the piping subassembly or system provided the minimum test pressure required for the piping system is met.

137.4.2 Provision of Air Vents at High Points. Vents shall be provided at all high points of the piping system in the position in which the test is to be

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:42 2005

conducted to purge air pockets while the component or system is filling. Venting during the filling of the system may be provided by the loosening of flanges having a minimum of four bolts or by the use of equipment vents.

137.4.3 Test Medium. Water shall normally be used as the test medium unless otherwise specified by the Owner. Test water shall be clean and shall be of such quality as to minimize corrosion of the materials in the piping system. Further recommended precautions on the quality of test water used for hydrotesting of austenitic (300 series) and ferritic (400 series) stainless steels are contained in Appendix IV, para. IV-3.4.

137.4.4 Check of Test Equipment Before Applying Pressure. The test equipment shall be examined before pressure is applied to ensure that it is tightly connected. All low-pressure filling lines and all other items not subject to the test pressure shall be disconnected or isolated by valves or other suitable means.

137.4.5 Required Hydrostatic Test Pressure. The hydrostatic test pressure at any point in the piping system shall not be less than 1.5 times the design pressure, but shall not exceed the maximum allowable test pressure of any nonisolated components, such as vessels, pumps, or valves, nor shall it exceed the limits imposed by para. 102.3.3(B). The pressure shall be continuously maintained for a minimum time of 10 minutes and may then be reduced to the design pressure and held for such time as may be necessary to conduct the examinations for leakage. Examinations for leakage shall be made of all joints and connections. The piping system, exclusive of possible localized instances at pump or valve packing, shall show no visual evidence of weeping or leaking.

137.5 Pneumatic Testing

137.5.1 General. Except for preliminary testing in accordance with para. 137.5.4, pneumatic testing shall not be used unless the Owner specifies pneumatic testing or permits its use as an alternative. It is recommended that pneumatic testing be used only when one of the following conditions exists:

(A) when piping systems are so designed that they cannot be filled with water;

(B) when piping systems are to be used in services where traces of the testing medium cannot be tolerated.

137.5.2 Test Medium. The gas used as the test medium shall be nonflammable and nontoxic. Since compressed gas may be hazardous when used as a testing medium, it is recommended that special precautions for protection of personnel be observed when a gas under pressure is used as the test medium.

137.5.3 Check of Test Equipment Before Applying Pressure. The test equipment shall be examined before pressure is applied to ensure that it is tightly connected. All items not subjected to the test pressure shall be disconnected or isolated by valves or other suitable means.

137.5.4 Preliminary Test. A preliminary pneumatic test not to exceed 25 psig [175 kPa (gage)] may be applied, prior to other methods of leak testing, as a means of locating major leaks. If used, the preliminary pneumatic test shall be performed in accordance with the requirements of paras. 137.5.2 and 137.5.3.

137.5.5 Required Pneumatic Test Pressure. The pneumatic test pressure shall be not less than 1.2 nor more than 1.5 times the design pressure of the piping system. The test pressure shall not exceed the maximum allowable test pressure of any nonisolated component, such as vessels, pumps, or valves, in the system. The pressure in the system shall gradually be increased to not more than one-half of the test pressure, after which the pressure shall be increased in steps of approximately one-tenth of the test pressure until the required test pressure has been reached. The pressure shall be continuously maintained for a minimum time of 10 minutes. It shall then be reduced to the lesser of design pressure or 100 psig [700 kPa (gage)] and held for such time as may be necessary to conduct the examination for leakage. Examination for leakage detected by soap bubble or equivalent method shall be made of all joints and connections. The piping system, exclusive of possible localized instances at pump or valve packing, shall show no evidence of leaking.

137.6 Mass-Spectrometer and Halide Testing

137.6.1 When specified by the Owner, systems with conditions of operation and design that require testing methods having a greater degree of sensitivity than can be obtained by a hydrostatic or pneumatic test shall be tested by a method, such as helium mass-spectrometer test or halide test, which has the required sensitivity.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:54:42 2005

137.6.2 When a mass-spectrometer or halide test is performed, it shall be conducted in accordance with the instructions of the manufacturer of the test equipment. In all cases a calibrated reference leak, with a leak rate not greater than the maximum permissible leakage from the system, shall be used. The equipment shall be calibrated against the reference leak in such a way that the system leakage measured by the equipment can be determined to be not greater than the leak rate of the reference leak.

137.7 Initial Service Testing

137.7.1 When specified by the owner, an initial service test and examination is acceptable when other types of tests are not practical or when leak tightness is demonstrable due to the nature of the service. One example is piping where shut-off valves are not available for isolating a line and where temporary closures are impractical. Others may be systems where during the course of checking out of pumps, compressors, or other equipment, ample opportunity is afforded for examination for leakage prior to full scale operation. An initial service test is not applicable to boiler external piping.

137.7.2 When performing an initial service test, the piping system shall be gradually brought up to normal operating pressure and continuously held for a minimum time of 10 minutes. Examination for leakage shall be made of all joints and connections. The piping system exclusive of possible localized instances at pump or valve packing shall show no visual evidence of weeping or leaking.

137.8 Retesting After Repair or Additions

137.8.1 Repairs may be made to the pressure parts of boiler external piping after the hydrostatic test required by para. 137.3.1, provided the requirements of PW-54.2 of Section I of the ASME Boiler and Pressure Vessel Code are met.

137.8.2 Nonpressure parts may be welded to the pressure parts of boiler external piping after the hydrostatic test required by para. 137.3.1, provided the requirements of PW-54.3 of Section I of the ASME Boiler and Pressure Vessel Code are met.

137.8.3 In the event repairs or additions to nonboiler external piping are made following a test, the affected piping shall be retested in accordance with the provisions of para. 137.3.2. However, a system need not be retested after seal welding or after attachments of lugs, brackets, insulation supports, nameplates, or other nonpressure retaining attachments provided:

(A) the attachment fillet weld does not exceed $^3/_8$ in. (10.0 mm) thickness or, if a full penetration weld is used, the material attached does not exceed the nominal thickness of the pressure retaining member or $^1/_2$ in. (12.0 mm), whichever is less;

(B) welds shall be preheated as required by para. 131;

(C) welds shall be examined as required by Table 136.4;

(D) seal welds shall be examined for leakage after system startup.

137.8.4 All weld defect repairs shall be made in accordance with para. 127.4.11.

TABLE A-1
CARBON STEEL (CONT'D)

Spec. No.	Grade	Type or Class	Nominal Composition	P-No.	Notes	Specified Minimum Tensile, ksi	Specified Minimum Yield, ksi	*E* or *F*
Bolts, Nuts, and Studs (Cont'd)								
A 307	B	...	C	...	(1)(13)(21)	60	...	...
A 449	...	...	C	...	(1)(17)(18)	120	...	...
	...	...	C	...	(1)(17)(19)	105	...	...
	...	...	C	...	(1)(17)(20)	90	...	...

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM, except API-5L. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers indicated in this Table are identical to those adopted by ASME Boiler and Pressure Vessel Code. Qualification of welding procedures, welders and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code (Section IX) except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given except as permitted by para. 122.6.2(G).

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure–temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) All the materials listed are classifed as ferritic [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR CONSTRUCTION OF PRESSURE RETAINING PARTS OF BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) AND (B).

(2) Upon prolonged exposure to temperatures above 775°F, the carbide phase of carbon steel may be converted to graphite.

(3) The allowable stress values given are for pipe fabricated from plate not exceeding $2^1/_2$ in. in thickness.

(4) This material shall not be used for flammable fluids. Refer to para. 105.2.1(A).

(5) Tensile value in parentheses is expected minimum.

(6) The 0.80 material quality factor for casting may be increased in accordance with para. 102.4.6.

7.0	7.0	7.0	7.0	...	...	...	...	...	...	...	B	A 307
23.0	23.0	23.0	23.0	23.0	23.0	23.0	...	...	...	...	...	A 449
23.0	20.3	20.3	20.3	20.3	20.3	20.3	...	...	...	...	...	
14.5	14.5	14.5	14.5	14.5	14.5	14.5	...	...	...	...	...	

NOTES (CONT'D)

(7) The stress values for structural quality plate include a material quality factor of 0.92. The allowable stresses for A 283 Grade D and A 36 plate have been limited to 12.7 ksi.
(8) These stress values are permitted only if killed or semikilled steels are used.
(9) A 254 is copper brazed (not welded) steel pipe.
(10) For saturated steam at 250 psi (406°F), the values given for 400°F may be used.
(11) For A 193 alloy and stainless steel bolts for use with carbon steel piping, see Tables A-2 and A-3.
(12) This is a product specification. Allowable stresses are not necessary. Limitations on metal temperature for materials covered by this specification for use under B31.1 are:

Grades 1 and 2	−20°F to 600°F
Grade 2H	−20°F to 800°F

(13) This material shall not be used above 400°F. The allowable stress value is 7000 psi.
(14) This material is not listed in the ASME Boiler and Pressure Vessel Code, Section IX. However, weld procedures shall be qualified in accordance with the P-Number shown. See para. 127.5.1.
(15) This material shall not be used in nominal wall thicknesses exceeding $^3/_4$ in.
(16) These allowable stress values are for pipe made using a butt-welded joint process. Pipe made by other processes shall not be used.
(17) These allowable stress values are established from a consideration of strength only and will be satisfactory for average service. For bolted joints, where freedom from leakage over a long period of time without retightening is required, lower stress values may be necessary as determined from the relative flexibility of the flange, bolts, and corresponding relaxation properties.
(18) These allowable stress values apply to bolting materials less than or equal to 1 in. diameter.
(19) These allowable stress values apply to bolting materials greater than 1 in. diameter and less than or equal to $1^1/_2$ in.
(20) These allowable stress values apply to bolting materials greater than $1^1/_2$ in. diameter and less than or equal to 3 in. diameter.
(21) The allowable stress values listed in MSS SP-58 for this material may be used for pipe supporting elements designed in accordance with MSS SP-58.
(22) These values apply to material less than or equal to 1 in. thick.
(23) These values apply to material greater than 1 in. thick.

TABLE A-2 (CONT'D)

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.
(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.
(c) The P-Numbers indicated in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5
(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."
(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.
(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.
(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.
(h) All the materials listed are classifed as ferritic [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) AND (B).
(2) Upon prolonged exposure to temperature above 875°F, the carbide phase of carbon-molybdenum steel may be converted to graphite.
(3) These allowable stress values apply to normalized and tempered material only.
(4) The material quality factors and allowable stress values for these materials may be increased in accordance with para. 102.4.6.
(5) At 400°F and below, the following allowable stress values apply:

Spec. No.	Grade	Type or Class	Specified Minimum Tensile, ksi	Specified Minimum Yield, ksi	E or F	Metal Temperature, °F: −20 to 100	200	300	400

	V	E	65	46	0.85	13.4	...	...	...

(6) If A 234 Grade WP-12 fittings are made from A 387 Grade 12 annealed plate, the allowable stress values shall be reduced by the ratio of 55 divided by 60 in the temperature range −20°F through 850°F. At 900°F through 1100°F, the values shown may be used.

(7) The mutual quality factor for centrifugally cast pipe (0.85) is based on all surfaces being machined, after heat treatment, to a surface finish of 250 μin. arithmetic average deviation or better.

(8) These allowable stress values are established from a consideration of strength only and will be satisfactory for average service. For bolted joints, where freedom from leakage over a long period of time without retightening is required, lower stress values may be necessary as determined from the relative flexibility of the flange and bolts and corresponding relaxation properties.

(9) Between temperatures of −20°F and 400°F, allowable stress values equal to the lower of the following may be used: 20% of the specified tensile strength, or 25% of the specified yield strength.

(10) This is a product specification. Allowable stress values are not necessary. Limitations on metal temperature for materials covered by this specification for use under ASME B31.1 are:

Grade 3	−20°F to 1100°F
Grade 4	−20°F to 900°F

(11) These allowable stress values are for pipe fabricated from ASTM A 387 Class 1 plate in the annealed condition.

(12) These allowable stress values are for pipe fabricated from ASTM A 387 Class 2 plate.

(13) These allowable stress values apply to bolting materials 4 in. in diameter and smaller.

(14) These allowable stress values apply to bolting materials $2^1/_2$ in. but not larger than 4 in. in diameter.

(15) These allowable stress values apply to bolting materials larger than $2^1/_2$ in. but not larger than 4 in. in diameter.

01 TABLE A-2 (CONT'D)

NOTES (CONT'D):

(16) These allowable stress values apply to bolting materials larger than 4 in. but not larger than 7 in. in diameter.
(17) For use at temperatures above 850°F, the carbon content of the base material and, where applicable, weld filler metal shall be 0.05% or higher. See para. 124.2(D).
(18) Minimum tempering temperature shall be 800°F.
(19) These allowable stress values apply to thickness less than 3 in.
(20) These allowable stress values apply to thickness 3 in. or greater.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.
(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.
(c) The P-Numbers indicated in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code. *Qualification of* welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.
(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."
(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.
(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. *Weld joint efficiency* factors are shown in Table 102.4.3.
(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) AND (B).
(2) Use of this material at temperatures above 650°F is not approved because of the possibility of temper embrittlement.
(3) This steel may be expected to develop embrittlement at room temperature after service at temperatures above 700°F. Consequently, its use at higher temperatures is not recommended unless due caution is observed.
(4) For fittings made from A 182 forgings over 5 in. in thickness, the allowable stress values tabulated shall be reduced by the ratio of 70 divided by 75.
(5) The material quality factors and allowable stress values for these materials may be increased in accordance with para. 102.4.6.
(6) Tensile strengths in parentheses are expected minimum values.
(7) See MSS SP-43 for requirements for lightweight stainless steel fittings. MSS SP-43 Schedule 5S fittings shall not be used for design temperatures above 400°F. MSS SP-43 Schedule 10S fittings shall not be used for design temperatures above 750°F.
(8) The material quality factor for centrifugally cast pipe (0.85) is based on all surfaces being machined after heat treatment. The surface finish, after machining, shall be 250 μin. arithmetic average deviation or smoother.
(9) Due to relatively low yield strength of these materials, these higher allowable stress values were established at temperatures where the short time tensile properties govern to permit the use of these alloys where slightly greater deformation is acceptable. These stress values exceed 67% but do not exceed 90% of the yield strength at temperature. Use of these stress values may result in dimensional changes due to permanent strain. These values should not be used for the flanges of gasketed joints or other applications where slight amounts of distortion can cause leakage or malfunction.
(10) The allowable stress vlaues tabulated for temperatures over 1000°F apply only if the carbon content of the material is 0.04% or higher.
(11) The allowable stress values tabulated for temperatures over 1000°F apply only if the material is heat treated by heating to a *minimum* temperature of 1900°F and quenching in water or rapidly cooling by other means.
(12) These allowable stress values apply to forgings over 5 in. in thickness.

																		Bar (Cont'd) Ferritic/Martensitic	
16.2	16.2	15.9	15.9	15.9	15.9	15.9	...	...	...	...	...	...	...	...	...	...	...	TPXM-27	A 479

NOTES (CONT'D):

(13) The allowable stress values tabulated for temperatures over 800°F apply only if the carbon content of the material is 0.04% or higher.

(14) These allowable stress values shall be used only when the grain size of the material is ASTM No. 6 or coarser.

(15) These allowable stress values shall be used when the grain size of the material is finer than ASTM No. 6 or when the grain size has not been determined.

(16) These stress values are established from a consideration of strength only and will be satisfactory for average service. For bolted joints, where freedom from leakage over a long period of time without retightening is required, lower stress values may be necessary as determined from the relative flexibility of the flange and bolts and corresponding relaxation properties.

(17) This is a product specification. Allowable stress values are not necessary. Limitations on metal temperature for materials covered by this specification for use under B31.1 are:

Grade 6 and 8F	−20°F to 800°F
Grades 8, 8C, 8M, & 8T	−20°F to 1200°F

(18) The hardness of this material, under the thread roots, shall not exceed Rockwell C35. The hardness shall be measured on a flat area, at least $^1/_8$ in. across, prepared by removing thread. No more material than necessary shall be removed to prepare the flat area. Hardness measurements shall be made at the same frequency as tensile test.

(19) These allowable stress values apply to bolting materials 4 in. in diameter and smaller.

(20) These allowable stress values apply to bolting materials $^3/_4$ in. in diameter and smaller.

(21) These allowable stress values apply to bolting materials larger than $^3/_4$ in. but not larger than 1 in. in diameter.

(22) These allowable stress values apply to bolting materials larger than 1 in. but not larger than $1^1/_4$ in. in diameter.

(23) These allowable stress values apply to bolting materials larger than $1^1/_4$ in. but not larger than $1^1/_2$ in. in diameter.

(24) These allowable stress values apply to bolting materials 8 in. in diameter and smaller.

(25) Use of external pressure charts for material in the form of barstock is permitted for stiffening rings only.

(26) At the ferrite levels tabulated below, these materials will have significant reductions in Charpy V-notch toughness values at room temperature and below following service exposure at the indicated temperatures. This reduction indicates the potential for brittle fracture with high rate loading in the presence of sharp notches or cracks.

Ferrite Content	Service Temperature
5% and less	1100°F and above
10%	900°F and above
15%	800°F and above
20%	700°F and above
25%–30%	600°F and above
35%–40%	500°F and above

(27) This stress values at 1050°F and above shall be used only when the grain size is ASTM No. 6 or coarser.

(28) These allowable stress values apply to material that has been carbide solution treated.

(29) These allowable stress values apply for single or double butt welded pipe with radiography per para. 136.4.5.

(30) These allowable stress values apply for double butt welded pipe.

(31) These allowable stress values apply for single butt welded pipe.

(32) This material is one of the highest tensile strength materials approved for use in ASME pressure component applications and little fatigue data is available for it in the ASME database. Therefore, the designer shall consider this when calculating the allowable stress range for expansion stresses and provide appropriate design margins.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers indicated in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code. Qualification of welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this table shall not be used at design temperatures above those for which allowable stress values are given.

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) The y coefficient = 0.4 except where Note (7) applies [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) AND (B).

(2) Due to the relatively low yield strengths of these materials, these higher allowable stress values were established at temperatures where the short time tensile properties govern to permit the use of these alloys where slightly greater deformation is acceptable. These stress values exceed 67% but do not exceed 90% of the yield strength at temperature. Use of these values may result in dimensional changes due to permanent strain. These values should not be used for flanges of gasketed joints or other applications where slight amounts ofdistortion can cause leakage or malfunction.

(3) The maximum temperature is limited to 500°F because harder temper adversely affects design stress in the creep rupture temperature range.

(4) These values may be used for plate material only.

(5) These values apply to sizes NPS 5 and smaller.

(6) These values apply to sizes larger than NPS 5.

(7) See Table 104.1.2(A) for y coefficient value.

(8) Heat treatment after forming or welding is neither required nor prohibited. However, if heat treatment is applied, the solution annealing treatment shall consist of heating to a minimum temperature of 2025°F and then quenching in water or rapidly cooling by other means.

(9) These values apply to thickness less than $^3/_{16}$ in.

(10) These values apply to thickness from $^3/_{16}$ in. up to and including $^3/_4$ in.

(11) These values apply to thickness more than $^3/_4$ in.

(12) All filler metal, including consumable insert material, shall comply with the requirements of Section IX of the ASME Boiler and Pressure Vessel Code.

(13) This material is one of the highest tensile strength materials approved for use in ASME pressure component applications and little fatigue data is available for it in the ASME database. Therefore, the designer shall consider this when calculating the allowable stress range for expansion stresses and provide appropriate design margins.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) Cast iron components shall not be welded during fabrication or assembly as part of the piping system.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.

(f) The tabulated stress values for ductile cast iron materials are $S \times F$ (material quality factor). Material quality factors are not applicable to other types of cast iron.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) The y coefficient = 0.4 [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) AND (B).

(2) Material quality factors are not applicable to these materials.

(3) For saturated steam at 250 psi (406°F), the stress values given at 400°F may be used.

(4) For limitations on the use of this material, see para. 124.4.

(5) This material shall not be used where the design pressure exceeds 250 psig [1725 kPa(gage)] or where the design temperature exceeds 450°F (230°C).

(6) This material shall not be used for boiler external piping where the design pressure exceeds 350 psig [2415 kPa (gage)] or where the design temperature exceeds 450°F (230°C).

(7) Piping components conforming to either ASME B16.1 or ASME B16.4 may be used for boiler external piping, subject to all the requirements of the particular standard.

(8) For limitations on the use of this material, see para. 124.6.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers listed in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code, Qualification of welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given. However, for saturated steam at 250 psi (406°F), the allowable stress values given for 400°F may be used.

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) For limitations on the use of copper and copper alloys for flammable liquids and gases, refer to paras. 122.7, 122.8, and 124.7.

(i) The y coefficient = 0.4 [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) and (B).

(2) This material may be used for Boiler External Piping provided that the nominal size does not exceed 3 in., and the design temperature does not exceed 406°F. This material shall not be used for blowoff piping. Where threaded brass or copper pipe is used for feed water piping, it shall have a wall thickness not less than that required for schedule 80 steel pipe of the same nominal size.

(3) Welding or brazing of this material is not permitted.

(4) When this material is used for welded or brazed construction, the allowable stress values used shall not exceed those given for the same material in the annealed condition.

(5) Castings which are welded or repair welded shall be heat treated at 1150°F–1200°F, followed by moving-air cooling. The required time at temperature is based on the cross section thicknesses as follows:

(a) $1\frac{1}{2}$ hr for the first inch, or fraction thereof;

(b) $\frac{1}{2}$ hr for each additional inch or fraction thereof.

(6) Welds must be made by an electric fusion welding process involving the addition of filler metal.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers listed in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code. Qualification of welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) Aluminum and aluminum alloys shall not be used for flammable fluids within the boiler plant structure (see para. 122.7).

(i) The y coefficient = 0.4 [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) and (B).

(2) These allowable stress values are not applicable when either welding or thermal cutting is employed.

(3) These allowable stress values are not applicable when either welding or thermal cutting is employed. In such cases, the corresponding stress values for the O temper shall be used.

(4) These allowable stress values are 90% of those for the corresponding core material.

(5) These allowable stress values apply only to seamless pipe smaller than NPS 1 which is extruded and then drawn.

(6) These allowable stress values are not applicable when either welding or thermal cutting is employed. In such cases, the corresponding stress values for the welded condition shall be used.

								Castings
3.2	3.2	3.2	3.0	2.8	2.5	2.2	A24430	B 26
6.0	6.0	6.0	5.0	...	...	...	A03560	
5.0	5.0	5.0	4.9	4.3	3.3	1.9	A03560	

NOTES (CONT'D):

(7) The strength of a reduced-section tensile specimen is required to qualify welding procedures. Refer to the ASME Boiler and Pressure Vessel Code, Section IX, QW-150.

(8) Refer to the ASME Boiler and Pressure Vessel Code, Section VIII, Part UNF, NF-13(b) regarding stress corrosion.

(9) For stress relieved tempers (T351, T3510, T3511,T451, T4510, T4511,T651, T6510, and T6511) stress values for the material in the basic temper shall be used.

(10) These allowable stress values apply to all thicknesses of and sizes of seamless pipe. They also apply to seamless extruded tube in thicknesses up to and including 1.000 in.

(11) These allowable stress values are for die forgings.

(12) These allowable stress values are for hand forgings.

(13) For temperatures up to 300°F, these allowable stress values are 83% of those for the corresponding core material. At temperatures of 350°F and 400°F, these allowable stress values are 90% of those for the corresponding core material.

(14) These allowable stress values are for the tempers listed in the welded condition and are identical to those for the O temper.

(15) These allowable stress values are based on 100% radiography of the longitudinal weld in accordance with ASTM B 547, para. 11.

(16) These allowable stress values are based on spot radiography of the longitudinal weld in accordance with ASTM B 547, para. 11.

(17) These allowable stress values are for the heat treated tempers listed in the welded condition.

(18) The tension test specimen from plate which is not less than 0.500 in. thick is machined from the core and does not include the cladding alloy. Therefore, the allowable stress values for thicknesses less than 0.500 in. shall be used.

(19) The tension test specimen from plate which is not less than 0.500 in thick is machined from the core and does not include the cladding alloy. Therefore, these allowable stress values are 90% of those for the core material of the same thickness.

(20) The allowable stress values for seamless pipe in sizes NPS 1 and larger are as follows:

100 °F	3.5 ksi
150 °F	3.5 ksi
200 °F	3.4 ksi

(21) Stress values in restricted shear such as dowel bolts, or similar construction in which the shearing member is so restricted that the section under consideration would fail without reduction of areas shall be 0.80 times the values in the above Table.

(22) Stress values in bearing shall be 1.60 times the values in the above Table.

(23) ASTM B 210 does not include this alloy/grade of material.

	WP348H	S34809	...	18Cr–10Ni–Cb	8	(1)	75	30

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers listed in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code. Qualification of welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) All the materials listed are classified as austenitic [see Table 104.1.2(A)].

NOTES:
(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) and (B).
(2) These allowable stress values shall be used only if the carbon content of the material is 0.04% or higher.
(3) These allowable stress values tabulated shall be used only if the material is heat treated by heating to a minimum temperature of 1900°F and quenching in water or rapidly cooling by other means.
(4) These allowable stress values shall be used only when the grain size of the material is ASTM No. 6 or coarser.

GENERAL NOTES:

(a) The tabulated specifications are ANSI/ASTM or ASTM. For ASME Boiler and Pressure Vessel Code applications, see related specifications in Section II of the ASME Code.

(b) The stress values in this Table may be interpolated to determine values for intermediate temperatures.

(c) The P-Numbers listed in this Table are identical to those adopted by the ASME Boiler and Pressure Vessel Code. Qualification of welding procedures, welders, and welding operators is required and shall comply with the ASME Boiler and Pressure Vessel Code, Section IX, except as modified by para. 127.5.

(d) Tensile strengths and allowable stresses shown in "ksi" are "thousands of pounds per square inch."

(e) The materials listed in this Table shall not be used at design temperatures above those for which allowable stress values are given.

(f) The tabulated stress values are $S \times E$ (weld joint efficiency factor) or $S \times F$ (material quality factor), as applicable. Weld joint efficiency factors are shown in Table 102.4.3.

(g) Pressure-temperature ratings of piping components, as published in standards referenced in this Code, may be used for components meeting the requirements of those standards. The allowable stress values given in this Table are for use in designing piping components which are not manufactured in accordance with referenced standards.

(h) The y coefficient = 0.4 [see Table 104.1.2(A)].

NOTES:

(1) THIS MATERIAL IS NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE FIGS. 100.1.2(A) and (B).

(2) Filler metal shall not be used in the manufacture of welded pipe or tubing.

(3) Welding of this material is not permitted.

01 TABLE B-1 (CONT'D)

NOTES:
(1) These data are for information and it is not to be implied that materials are suitable for all the temperature ranges shown.
(2) Group 1 alloys (by nominal composition):

Carbon steels
(C, C–Si, C–Mn, and C–Mn–Si)
C–½Mo
½Cr–⅕Mo–V
½Cr–¼Mo–Si
½Cr–½Mo
½Cr–½Ni–¼Mo
¾Cr–½Ni–Cu
¾Cr–¾Ni–Cu–Al
1Cr–⅕Mo
1Cr–⅕Mo–Si
1Cr–½Mo
1Cr–½Mo–V
1¼Cr–½Mo
1¼Cr–½Mo–Si
1¾Cr–½Mo–Cu
2Cr–½Mo
2¼Cr–1Mo
3Cr–1Mo
½Ni–½Mo–V
½Ni–½Cr–¼Mo–V
¾Ni–½Mo–Cr–V
¾Ni–½Mo–⅓Cr–v
¾Ni–½Cu–Mo
¾Ni–½Cr–½Mo–V
¾Ni–1Mo–¾Cr
1Ni–½Cr–½Mo
1¼Ni–1Cr–½Mo
1¾Ni–¾Cr–¼Mo
2Ni–¾Cr–¼Mo
2Ni–¾Cr–⅓Mo
2½Ni
3½Ni
3½Ni–1¾Cr–½Mo–V

(3) Group 2 alloys (by nominal composition):

M–V
Mn–¾Mo
Mn–½Mo
Mn–½Mo–¼Ni
Mn–½Mo–½Ni
Mn–½Mo–¾Ni

NOTES:
(1) These data are for information and it is not to be implied that materials are suitable for all the temperature ranges shown.
(2) Group 1 alloys (by nominal composition):

Carbon steels
(C, C–Si, C–Mn, and C–Mn–Si)
C–½Mo
½Cr–½Mo–V
½Cr–¼Mo–Si
½Cr–½Mo
½Cr–½Ni–¼Mo
¾Cr–½Ni–Cu
¾Cr–¾Ni–Cu–Al
1Cr–½Mo
1Cr–½Mo–Si
1Cr–½Mo
1Cr–½Mo–V
1¼Cr–½Mo
1¼Cr–½Mo–Si
1¾Cr–½Mo–Cu
2Cr–½Mo
2¼Cr–1Mo
3Cr–1Mo
½Ni–½Mo–V
½Ni–½Cr–¼Mo–V
¾Ni–½Mo–Cr–V
¾Ni–½Mo–⅓Cr–V
¾Ni–½Cu–Mo
¾Ni–½Cr–½Mo–V
¾Ni–1Mo–¾Cr
1Ni–½Cr–½Mo
1¼Ni–1Cr–½Mo
1¾Ni–¾Cr–¼Mo
2Ni–¾Cr–¼Mo
2Ni–¾Cr–⅓Mo
2½Ni
3½Ni
3½Ni–1¾Cr–½Mo–V

(3) Group 2 alloys (by nominal composition):

M–V
Mn–¼Mo
Mn–½Mo
Mn–½Mo–¼Ni
Mn–½Mo–½Ni
Mn–½Mo–¾Ni

TABLE D-1
FLEXIBILITY AND STRESS INTENSIFICATION FACTORS (CONT'D)

Description	Flexibility Factor k	Stress Intensification Factor i	Sketch
Tapered transition per para. 127.4.2(B) and ASME B16.25 [Note (1)]	1	1.9 max. or $1.3 + 0.0036\frac{D_o}{t_n} + 3.6\frac{\delta}{t_n}$	Concentric reducer per ASME B16.9 [Note (7)]	1	2.0 max. or $0.5 + 0.01\alpha\left(\frac{D_2}{t_2}\right)^{1/2}$	Threaded pipe joint, or threaded flange	1	2.3	...
Corrugated straight pipe, or corrugated or creased bend [Note (8)]	5	2.5	...

NOTES:

(1) The following nomenclature applies to Table D-1:

B = length of miter segment at crotch, in. (mm)
D_o = outside diameter, in.
D_{ob} = outside diameter of branch, in. (mm)
R = bend radius of elbow or pipe bend, in. (mm)
r = mean radius of pipe, in. (mm) (matching pipe for tees)
r_x = external crotch radius of welded-in contour inserts, in. (mm)
s = miter spacing at center line, in. (mm)
T_c = crotch thickness of welded-in contour inserts, in. (mm)
t_n = nominal wall thickness of pipe, in. (mm) (matching pipe for tees)
t_r = reinforcement pad or saddle thickness, in. (mm)
α = reducer cone angle, deg.
δ = mismatch, in. (mm)
θ = one-half angle between adjacent miter axes, deg.

(2) The flexibility factors k and stress intensification factors i in Table D-1 apply to bending in any plane for fittings and shall in no case be taken less than unity. Both factors apply over the effective arc length (shown by heavy center lines in the sketches) for curved and miter elbows, and to the intersection point for tees. The values of k and i can be read directly from Chart D-1 by entering with the characteristic h computed from the formulas given.

(3) Where flanges are attached to one or both ends, the values of k and i in Table D-1 shall be multiplied by the factor c given below, which can be read directly from Chart D-2, entering with the computed h: one end flanged, $c = h^{1/6}$; both ends flanged, $c = h^{1/3}$.

(4) Also includes single miter joints.

(5) When $t_e > 1.5t_n$, $h = 4.05t_n/r$.

TABLE D-1 (CONT'D)

NOTES (CONT'D):

(6) The equation applies only if the following conditions are met.
- (a) The reinforcement area requirements of para. 104.3 are met.
- (b) The axis of the branch pipe is normal to the surface of run pipe wall.
- (c) For branch connections in a pipe, the arc distance measured between the centers of adjacent branches along the surface of the run pipe is not less than three times the sum of their inside radii in the longitudinal direction or is not less than two times the sum of their radii along the circumference of the run pipe.
- (d) The inside corner radius r_1 (see Fig. D-1) is between 10% and 50% of t_{nh}.
- (e) The outer radius r_2 (see Fig. D-1) is not less than the larger of $T_b/2$, $(T_b + y)/2$ [shown in Fig. D-1 sketch (c)], or $t_{nh}/2$.
- (f) The outer radius r_3 (see Fig. D-1) is not less than the larger of:
  - (1) $0.002\theta d_o$;
  - (2) $2(\sin\theta)^3$ times the offset for the configurations shown in Fig. D-1 sketches (a) and (b).
- (g) $R_m/t_{nh} \le 50$ and $rt_m/R_m \le 0.5$.

(7) The equation applies only if the following conditions are met:
- (a) Cone angle α does not exceed 60 deg., and the reducer is concentric.
- (b) The larger of D_1/t_1 and D_2/t_2 does not exceed 100.
- (c) The wall thickness is not less than t_1 throughout the body of the reducer, except in and immediately adjacent to the cylindrical portion on the small end, where the thickness shall not be less than t_2.

(8) Factors shown apply to bending; flexibility factor for torsion equals 0.9.

(9) The designer is cautioned that cast butt welding elbows may have considerably heavier walls than those of the pipe with which they are used. Large errors may be introduced unless the effect of these greater thicknesses is considered.

(10) The stress intensification factors in the Table were obtained from tests on full size outlet connections. For less than full size outlets, the full size values should be used until more applicable values are developed.

(11) A stress intensification factor of 1.3 may be used for socket weld fitting if toe weld blends smoothly with no undercut in pipe wall as shown in the concave, unequal leg fillet weld of Fig. 127.4.4(A).

(12) The stress intensification factors apply to girth butt welds between two items for which the wall thicknesses are between $0.875t$ and $1.10t$ for an axial distance of $\sqrt{D_o t}$. D_o and t are nominal outside diameter and nominal wall thickness, respectively. δ_{avg} is the average mismatch or offset.

(13) In large diameter thin-wall elbows and bends, pressure can significantly affect magnitudes of k and i. Values from the table may be corrected by dividing k by

$$\left[1 + 6\left(\frac{P}{E_c}\right)\left(\frac{r}{t_n}\right)^{7/3}\left(\frac{R}{r}\right)^{1/3}\right]$$

and dividing i by

$$\left[1 + 3.25\left(\frac{P}{E_c}\right)\left(\frac{r}{t_n}\right)^{5/2}\left(\frac{R}{r}\right)^{2/3}\right]$$

APPENDIX F
REFERENCED STANDARDS[1]
ASME B31.1-2001, POWER PIPING

Specific editions of standards incorporated in this Code by reference are shown in this issue of Appendix F. It is not practical to refer to a specific edition of each standard throughout the Code text, but instead, the specific edition reference dates are shown here. Appendix F will be revised at intervals as needed and issued. The names and addresses of the sponsoring organizations are also shown in this issue.

APPENDIX G
NOMENCLATURE

This Appendix is a compliation of the nomenclature used within this Code. Included are the term definitions and units that can be uniformly applied. These terms are also defined at a convenient location within the Code. When used elsewhere within the Code, definitions given here shall be understood to apply.

Symbol	Definition	Units		References	
		US	SI	Paragraph	Table/Fig./App.
A	Corrosion, erosion, and mechanical allowances (including threading, grooving)	in.	mm	104.1.2(A)[Eqs.(3), (3A), (4), (4A)] 104.4.1(B) 104.5.2(B) 104.5.3(A) 104.3.1	...
Area available for reinforcement:					
A_1	in run pipe	in.^{2}	mm^2	104.3.1(D.2)	104.3.1(D) 104.3.1(G)
A_2	in branch pipe	in.^{2}	mm^2	104.3.1(D.2)	104.3.1(D) 104.3.1(G)
A_3	by deposited metal beyond outside diameter of run and branch and for fillet weld attachments of rings, pads, and saddles	in.^{2}	mm^2	104.3.1(d.2)	104.3.1(D)
A_4	by reinforcing ring, pad, or integral reinforcement	in.^{2}	mm^2	104.3.1(D.2)	104.3.1(D) 104.3.1(G)
A_5	in saddle on right angle connection	in.^{2}	mm^2	104.3.1(D.2)	104.3.1(D)
A_7	Required reinforcement area	in.^{2}	mm^2	104.3.1(D.2)	104.3.1(D) 104.3.1(G)
b	Subscript referring to branch	...	...	104.3.1(D.2)	104.3.1(D)
c	Flanged elbow correction factor	...	...	...	Table D-1 Chart D-2
C	Cold-spring factor	...	...	119.10.1[Eqs. (9), (10)]	...
C_x	Size of fillet weld for socket welding components other than flanges	in.	mm	...	127.4.4(C)
d	Inside diameter of pipe	in.	mm	104.1.2(A)[Eqs. (3A), (4A)]	...
d_1	Inside center line longitudinal direction of the finished branch opening in the run of the pipe	in.	mm	...	104.3.1(D)
d_2	Half-width of reinforcement zone	in.	mm	104.3.1(D.2)	104.3.1(D)
d_5	Diameter of finished opening	in.	mm	104.4.1(C)	...
d_6	Inside or pitch diameter of gasket	in.	mm	104.5.3(A)	...
d_b	Corroded internal diameter of branch pipe	in.	mm	104.3.1(G.4)	104.3.1(G)

APPENDIX H
PREPARATION OF TECHNICAL INQUIRIES

H-1 INTRODUCTION

The ASME B31 Committee, Code for Pressure Piping, will consider written requests for interpretations and revisions of the Code rules, and develop new rules if dictated by technical development. The Committee's activities in this regard are limited strictly to interpretations of the rules or to the consideration of revisions to the present rules on the basis of new data or technology. The Introduction to this Code states "It is the owner's responsibility to determine which Code Section is applicable to a piping installation." The Committee will not respond to inquiries requesting assignment of a Code Section to a piping installation. As a matter of published policy, ASME does not approve, certify, rate, or endorse any item, construction, proprietary device, or activity, and, accordingly, inquiries requiring such consideration will be returned. Moreover, ASME does not act as a consultant on specific engineering problems or on the general application or understanding of the Code rules. If, based on the inquiry information submitted, it is the opinion of the Committee that the inquirer should seek professional assistance, the inquiry will be returned with the recommendation that such assistance be obtained.

Inquiries that do not provide the information needed for the Committee's full understanding will be returned.

H-2 REQUIREMENTS

Inquiries shall be limited strictly to interpretations of the rules or to the consideration of revisions to the present rules on the basis of new data or technology. Inquiries shall meet the following requirements:

(a) Scope. Involve a single rule or closely related rules in the scope of the Code. An inquiry letter concerning unrelated subjects will be returned.

(b) Background. State the purpose of the inquiry, which may be either to obtain an interpretation of Code rules, or to propose consideration of a revision to the present rules. Provide concisely the information needed for the Committee's understanding of the inquiry, being sure to include reference to the applicable Code Section, Edition, Addenda, paragraphs, figures, and tables. If sketches are provided, they shall be limited to the scope of the inquiry.

(c) Inquiry Structure

(1) Proposed Question(s). The inquiry shall be stated in a condensed and precise question format, omitting superfluous background information, and, where appropriate, composed in such a way that "yes" or "no" (perhaps with provisos) would be an acceptable reply. The inquiry statement should be technically and editorially correct.

(2) Proposed Reply(ies). Provide a proposed reply stating what it is believed that the Code requires. If in the inquirer's opinion, a revision to the Code is needed, recommended wording shall be provided in addition to information justifying the change.

H-3 SUBMITTAL

Inquiries should be submitted in typewritten form; however, legible handwritten inquiries will be considered. They shall include the name and mailing address of the inquirer, and be mailed to the following address:

Secretary
ASME B31 Committee
Three Park Avenue
New York, NY 10016-5990

APPENDIX J
QUALITY CONTROL REQUIREMENTS FOR BOILER EXTERNAL PIPING (BEP)

FOREWORD

This Appendix contains the quality control requirements for boiler external piping. The following is that portion of Appendix A-300 Quality Control System of the ASME Boiler and Pressure Vessel Code, Section I, which is applicable to BEP.

J-1.0 QUALITY CONTROL SYSTEM

J-1.1 General

J-1.1.1 Quality Control System. The Manufacturer or assembler shall have and maintain a quality control system which will establish that all Code requirements, including material, design, fabrication, examination (by the Manufacturer), and inspection of boilers and boiler parts (by the Authorized Inspector), will be met. Provided that Code requirements are suitably identified, the system may include provisions for satisfying any requirements by the Manufacturer or user which exceed minimum Code requirements and may include provisions for quality control of non-Code work. In such systems, the Manufacturer may make changes in parts of the system which do not affect the Code requirements without securing acceptance by the Authorized Inspector. Before implementation, revisions to quality control systems of Manufacturers and assemblers of safety and safety relief valves shall have been found acceptable to an ASME designee if such revisions affect Code requirements.

The system that the Manufacturer or assembler uses to meet the requirements of this Section must be one suitable for his own circumstances. The necessary scope and detail of the system shall depend on the complexity of the work performed and on the size and complexity of the Manufacturer's (or assembler's) organization. A written description of the system the Manufacturer or assembler will use to produce a Code item shall be available for review. Depending upon the circumstances, the description may be brief or voluminous.

The written description may contain information of proprietary nature relating to the Manufacturer's (or assembler's) processes. Therefore, the Code does not require any distribution of this information, except for the Authorized Inspector or ASME designee.

It is intended that information learned about the system in connection with evaluation will be treated as confidential and that all loaned descriptions will be returned to the Manufacturer upon completion of the evaluation.

J-1.2 Outline of Features to Be Included in the Written Description of the Quality Control System

The following is a guide to some of the features which should be covered in the written description of the quality control system and which is equally applicable to both shop and field work.

J-1.2.1 Authority and Responsibility. The authority and responsibility of those in charge of the quality control system shall be clearly established. Persons performing quality control functions shall have sufficient and well-defined responsibility, the authority, and the organizational freedom to identify quality control problems and to initiate, recommend, and provide solutions.

J-1.2.2 Organization. An organization chart showing the relationship between management and engineering, purchasing, manufacturing, field assembling, inspection, and quality control is required to reflect the actual organization. The purpose of this chart is to identify and associate the various organizational groups with the particular function for which they are responsible. The Code does not intend to encroach on the Manufacturer's right to establish, and from time to time to alter, whatever form of organization the Manufacturer considers appropriate for its Code work.

J-1.2.3 Drawings, Design Calculations, and Specification Control. The Manufacturer's or assembler's quality control system shall provide procedures which will assure that the latest applicable drawings, design

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:44 2005

calculations, specifications, and instructions, required by the Code, as well as authorized changes, are used for manufacture, assembly, examination, inspection, and testing.

J-1.2.4 Material Control. The Manufacturer or assembler shall include a system of receiving control which will insure that the material received is properly identified and has documentation, including required material certifications or material test reports, to satisfy Code requirements as ordered. The material control system shall insure that only the intended material is used in Code construction.

J-1.2.5 Examination and Inspection Program. The Manufacturer's quality control system shall describe the fabrication operations, including examinations, sufficiently to permit the Authorized Inspector to determine at what stages specific inspections are to be performed.

J-1.2.6 Correction of Nonconformities. There shall be a system agreed upon with the Authorized Inspector for correction of nonconformities. A nonconformity is any condition which does not comply with the applicable rules of this Section. Nonconformities must be corrected or eliminated in some way before the completed component can be considered to comply with this Section.

J-1.2.7 Welding. The quality control system shall include provisions for indicating that welding conforms to requirements of Section IX as supplemented by this Section.

J-1.2.8 Nondestructive Examination. The quality control system shall include provisions for identifying nondestructive examination procedures the Manufacturer will apply to conform with requirements of this Section.

J-1.2.9 Heat Treatment. The quality control system shall provide controls to assure that heat treatments as required by the rules of this Section are applied. Means shall be indicated by which the Authorized Inspector can satisfy himself that these Code heat treatment requirements are met. This may be by review of furnace time – temperature records or by other methods as appropriate.

J-1.2.10 Calibration of Measurement and Test Equipment. The Manufacturer or assembler shall have a system for the calibration of examination, measuring, and test equipment used in fulfillment of requirements of this Section.

J-1.2.11 Records Retention. The Manufacturer or assembler shall have a system for the maintenance of radiographs and Manufacturers' Data Reports as required by this Section.

J-1.2.12 Sample Forms. The forms used in the quality control system and any detailed procedures for their use shall be available for review. The written description shall make necessary references to these forms.

J-1.2.13 Inspection of Boilers and Boiler Parts

J-1.2.13.1 Inspection of boilers and boiler parts shall be by the Authorized Inspector described in PG-91.

J-1.2.13.2 The written description of the quality control system shall include reference to the Authorized Inspector.

J-1.2.13.2.1 The Manufacturer (or assembler) shall make available to the Authorized Inspector at the Manufacturer's plant (or construction site) a current copy of the written description or the applicable quality control system.

J-1.2.13.2.2 The Manufacturer's quality control system shall provide for the Authorized Inspector at the Manufacturer's plant to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the Inspector to perform his duties in accordance with this Section. The Manufacturer may provide such access either to his own files of such documents or by providing copies to the Inspector.

J-1.2.14 Inspection of Safety and Safety Relief Valves

J-1.2.14.1 Inspection of safety and safety relief valves shall be by designated representative of the ASME, as described in PG-73.3.

J-1.2.14.2 The written description of the quality control system shall include reference to the ASME designee.

J-1.2.14.2.1 The valve Manufacturer (or assembler) shall make available to the ASME designee at the Manufacturer's plant a current copy of the written description of the applicable quality control system.

J-1.2.14.2.2 The valve Manufacturer's (or assembler's) quality control system shall provide for the ASME designee to have access to all drawings, calculations, specifications, procedures, process sheets, repair procedures, records, test results, and any other documents as necessary for the designee to perform his duties in accordance with this Section. The Manufacturer may provide such access either to his own files of such documents or by providing copies to the designee.

NONMANDATORY APPENDIX II[1]
RULES FOR THE DESIGN OF SAFETY VALVE INSTALLATIONS

FOREWORD

ASME B31.1 contains rules governing the design, fabrication, materials, erection, and examination of power piping systems. Experience over the years has demonstrated that these rules may be reasonably applied to safety valve installations. Nevertheless, instances have occurred wherein the design of safety valve installations may not have properly and fully applied the ASME B31.1 rules. Accordingly, this nonmandatory Appendix to ASME B31.1 has been prepared to illustrate and clarify the application of ASME B31.1 rules to safety valve installations. To this end, Appendix II presents the designer with design guidelines and alternative design methods.

II-1.0 SCOPE AND DEFINITION

II-1.1 Scope

The scope of Appendix II is confined to the design of the safety valve installations as defined in para. 1.2 of this Appendix. The loads acting at the safety valve station will affect the bending moments and stresses in the complete piping system, out to its anchors and/or extremities, and it is the designer's responsibility to consider these loads. Appendix II, however, deals primarily with the safety valve installation, and not the complete piping system.

The design of the safety valve installation requires that careful attention be paid to:

(1) all loads acting on the system;

(2) the forces and bending moments in the piping and piping components resulting from the loads;

(3) the loading and stress criteria; and

(4) general design practices.

All components in the safety valve installation must be given consideration, including the complete piping system, the connection to the main header, the safety valve, valve and pipe flanges, the downstream discharge or vent piping, and the system supports. The scope of this Appendix is intended to cover all loads on all components. It is assumed that the safety valve complies with the requirements of American National Standards prescribed by ASME B31.1 for structural integrity.

This Appendix has application to either safety, relief, or safety-relief valve installations. For convenience, however, the overpressure protection device is generally referred to as a safety valve. The loads associated with relief or safety-relief valve operation may differ significantly from those of safety valve operation, but otherwise the rules contained herein are equally applicable to each type of valve installation. See para. II-1.2 for definition.

This Appendix provides analytic and nomenclature definition figures to assist the designer, and is not intended to provide actual design layout (drains, drip pans, suspension, air gaps, flanges, weld ends, and other design details are not shown). Sample problems have been provided at the end of the text to assist the designer in application of the rules in this Appendix.

II-1.2 Definitions (Valve Descriptions Follow the Definitions Given in Section I of the ASME Boiler and Pressure Vessel Code)

Safety Valve: an automatic pressure relieving device actuated by the static pressure upstream of the valve and characterized by full opening pop action. It is used for gas or vapor service.

Relief Valve: an automatic pressure relieving device actuated by the static pressure upstream of the valve which opens further with the increase in pressure over the opening pressure. It is used primarily for liquid service.

Safety Relief Valve: an automatic pressure actuated relieving device suitable for use either as a safety valve or relief valve, depending on application.

Power-Actuated Pressure Relieving Valve: a relieving device whose movements to open or close are fully controlled by a source of power (electricity, air, steam,

[1] Nonmandatory Appendices are identified by a Roman numeral; mandatory Appendices are identified by a letter. Therefore, Roman numeral I is not used in order to avoid confusion with the letter I.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:44 2005

or hydraulic). The valve may discharge to atmosphere or to a container at lower pressure. The discharge capacity may be affected by the downstream conditions, and such effects shall be taken into account. If the power-actuated pressure relieving valves are also positioned in response to other control signals, the control impulse to prevent overpressure shall be responsive only to pressure and shall override any other control function.

Open Discharge Installation: an installation where the fluid is discharged directly to the atmosphere or to a vent pipe that is uncoupled from the safety valve. Figure II-1-2(A) shows a typical open discharge installation with an elbow installed at the valve discharge to direct the flow into a vent pipe. The values for l and m on Fig. II-1-2(A) are upper limits for which the rules for open discharge systems may be used. l shall be limited to a value less than or equal to $4D_o$; m shall be limited to a value less than or equal to $6D_o$ where D_o is the outside diameter of the discharge pipe. Open discharge systems which do not conform to these limits shall be evaluated by the designer for the applicability of these rules.

Closed Discharge Installation: an installation where the effluent is carried to a distant spot by a discharge pipe which is connected directly to the safety valve. Figure II-1-2(B) shows a typical closed discharge system.

Safety Valve Installation: the safety valve installation is defined as that portion of the system shown on Figs. II-1-2(A) and II-1-2(B). It includes the run pipe, branch connection, the inlet pipe, the valve, the discharge piping, and the vent pipe. Also included are the components used to support the system for all static and dynamic loads.

II-2.0 LOADS

II-2.1 Thermal Expansion

Loads acting on the components in the safety valve installation and the displacements at various points due to thermal expansion of the piping shall be determined by analyzing the complete piping system out to its anchors, in accordance with procedures in para. 119.

II-2.1.1 Installations with Open Discharge. For safety valve installations with open discharge, there will be no thermal expansion loads acting on the discharge elbow, the valve, or the valve inlet other than that from restraint to thermal expansion as described below. Restraint to thermal expansion can sometimes occur due to drain lines, or when structural supports are provided to carry the reaction forces associated with safety valve lift. Examples of such structural supports are shown in Fig. II-6-1 sketch (b). When such restraints exist, the thermal expansion loads and stresses shall be calculated and effects evaluated.

II-2.1.2 Installations with Closed Discharge. Loads due to thermal expansion and back pressure of a safety valve installation with a closed discharge can be high enough to cause malfunction of the valve, excessive leakage of the valve or flange, or overstress of other components. The loads due to thermal expansion shall be evaluated for all significant temperature combinations, including the cases where the discharge piping is hot following safety valve operation.

II-2.2 Pressure

Pressure loads acting on the safety valve installation are important from two main considerations. The first consideration is that the pressure acting on the walls of the safety valve installation can cause membrane stresses which could result in rupture of the pressure retaining parts. The second consideration is that the pressure effects associated with discharge can cause high loads acting on the system which create bending moments throughout the piping system. These pressure effects are covered in para. II-2.3.

All parts of the safety valve installation must be designed to withstand the design pressures without exceeding the Code allowable stresses. The branch connection, the inlet pipe, and the inlet flanges shall be designed for the same design pressure as that of the run pipe. The design pressure of the discharge system will depend on the safety valve rating and on the configuration of the discharge piping. The open discharge installation and the closed discharge installation present somewhat different problems in the determination of design pressures, and these problems are discussed in the paragraphs below.

II-2.2.1 Design Pressure and Velocity for Open Discharge Installation Discharge Elbows and Vent Pipes. There are several methods available to the designer for determining the design pressure and velocity in the discharge elbow and vent pipe. It is the responsibility of the designer to assure himself that the method used yields conservative results. A method for determining the design pressures and velocities in the discharge elbow and vent pipe for open discharge

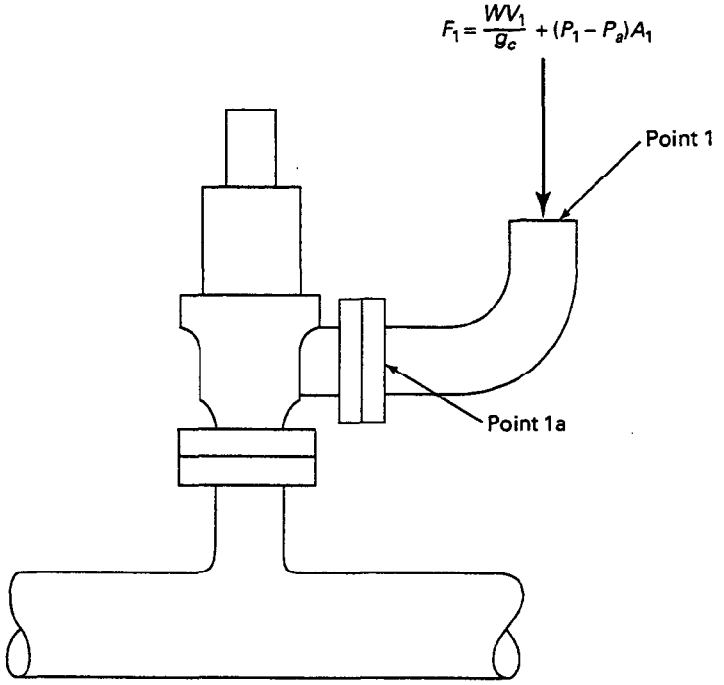

FIG. II-2-1

installation is shown below and illustrated in the sample problem.

First, calculate the design pressure and velocity for the discharge elbow.

(1) Determine the pressure P_1 that exists at the discharge elbow outlet (Fig. II-2-1).

$$P_1 = \frac{W}{A_1}\frac{(b-1)}{b}\sqrt{\frac{2(h_o - a)J}{g_c(2b-1)}}$$

(2) Determine the velocity V_1 that exists at the discharge elbow outlet (Fig. II-2-1).

$$V_1 = \sqrt{\frac{2g_cJ(h_o - a)}{(2b-1)}}$$

where

W = actual mass flow rate, lbm/sec
A_1 = discharge elbow area, in.^{2}
h_o = stagnation enthalpy at the safety valve inlet, Btu/lbm
J = 778.16 ft-lbf/Btu
g_c = gravitational constant = 32.2 lbm-ft/lbf-sec^2
P_1 = pressure, psia (lbf/in.^{2}, absolute)
V_1 = ft/sec

TABLE II-2.2.1

Steam Condition	*a*, Btu/lbm	*b*
Wet steam, < 90% quality	291	11
Saturated steam, ≥ 90% quality, 15 psia ≤ P_1 ≤ 1000 psia	823	4.33
Superheated steam, ≥ 90% quality, 1000 psia < P_1 ≤ 2000 psia[1]	831	4.33

NOTE:
(1) This method may be used as an approximation for pressures > 2000 psi, but an alternate method should be used for verification.

Common values of a and b are listed in Table II-2.2.1.

(3) Determine the safety valve outlet pressure P_{1a} at the inlet to the discharge elbow (Fig. II-2-1).

(3.1) Determine the length to diameter ratio (dimensionless) for the pipe sections in the discharge elbow (L/D).

$$L/D = \frac{L_{max.}}{D}$$

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:46 2005

(3.2) Determine a Darcy-Weisbach friction factor f to be used. (For steam, a value of 0.013 can be used as a good estimate since f will vary slightly in turbulent pipe flow.)

(3.3) Determine a specific heat ratio (for superheated steam, $k = 1.3$ can be used as an estimate — for saturated steam, $k = 1.1$).

(3.4) Calculate:

$$f\left(\frac{L_{max.}}{D}\right)$$

(3.5) Enter Chart II-1 with value of

$$f\left(\frac{L_{max.}}{D}\right)$$

and determine P/P^*.

(3.6) $P_{1a} = P_1\ (P/P^*)$

(3.7) P_{1a} is the maximum operating pressure of the discharge elbow.

Secondly, determine the design pressure and velocity for the vent pipe.

(1) Determine the pressure P_3 that exists at the vent pipe outlet (Fig. II-2-2).

$$P_3 = P_1\left(\frac{A_1}{A_3}\right)$$

(2) Determine the velocity V_3 that exists at the vent pipe outlet (Fig. II-2-2).

$$V_3 = V_1$$

(3) Repeat Steps (3.1) to (3.7) in the calculation of the discharge elbow maximum operating pressure to determine the maximum operating pressure of the vent pipe.

(4) Determine the velocity V_2 and pressure P_2 that exists at the inlet to the vent pipe (Fig. II-2-2).

(4.1) Enter Chart II-1[2] with value of

$$f\left(\frac{L_{max.}}{D}\right)$$

from Step (3.4) and determine value of V/V^* and P/P^*.

(4.2) Calculate V_2

$$V_2 = V_3\ (V/V^*)$$

(4.3) P_2, $P_2 = P_3\ (P/P^*)$. This is the highest pressure the vent stack will see and should be used in calculating vent pipe blow back (see para. II-2.3.1.2).

II-2.2.2 Pressure for Closed Discharge Installations. The pressures in a closed discharge pipe during steady state flow may be determined by the methods described in para. II-2.2.1. However, when a safety valve discharge is connected to a relatively long run of pipe and is suddenly opened, there is a period of transient flow until the steady state discharge condition is reached. During this transient period, the pressure and flow will not be uniform. When the safety valve is initially opened, the discharge pipe may be filled with air. If the safety valve is on a steam system, the steam discharge from the valve must purge the air from the pipe before steady state steam flow is established and, as the pressure builds up at the valve outlet flange and waves start to travel down the discharge pipe, the pressure wave initially emanating from the valve will steepen as it propagates, and it may steepen into a shock wave before it reaches the exit. Because of this, it is recommended that the design pressure of the closed discharge pipe be greater than the steady state operating pressure by a factor of at least 2.

II-2.3 Reaction Forces From Valve Discharge

It is the responsibility of the piping system designer to determine the reaction forces associated with valve discharge. These forces can create bending moments at various points in the piping system so high as to cause catastrophic failure of the pressure boundary parts. Since the magnitude of the forces may differ substantially, depending on the type of discharge system, each system type is discussed in the paragraphs below.

II-2.3.1 Reaction Forces With Open Discharge Systems

II-2.3.1.1 Discharge Elbow. The reaction force F due to steady state flow following the opening of the safety valve includes both momentum and pressure effects. The reaction force applied is shown in Fig. II-2-1, and may be computed by the following equation.

[2] Chart II-1 may be extended to other values of f (L_{max}/D) by use of the Keenan and Kaye Gas Tables for Fanno lines. The Darcy-Weisbach friction factor is used in Chart II-1, whereas the Gas Tables use the Fanning factor which is one-fourth the value of the Darcy-Weisbach factor.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:46 2005

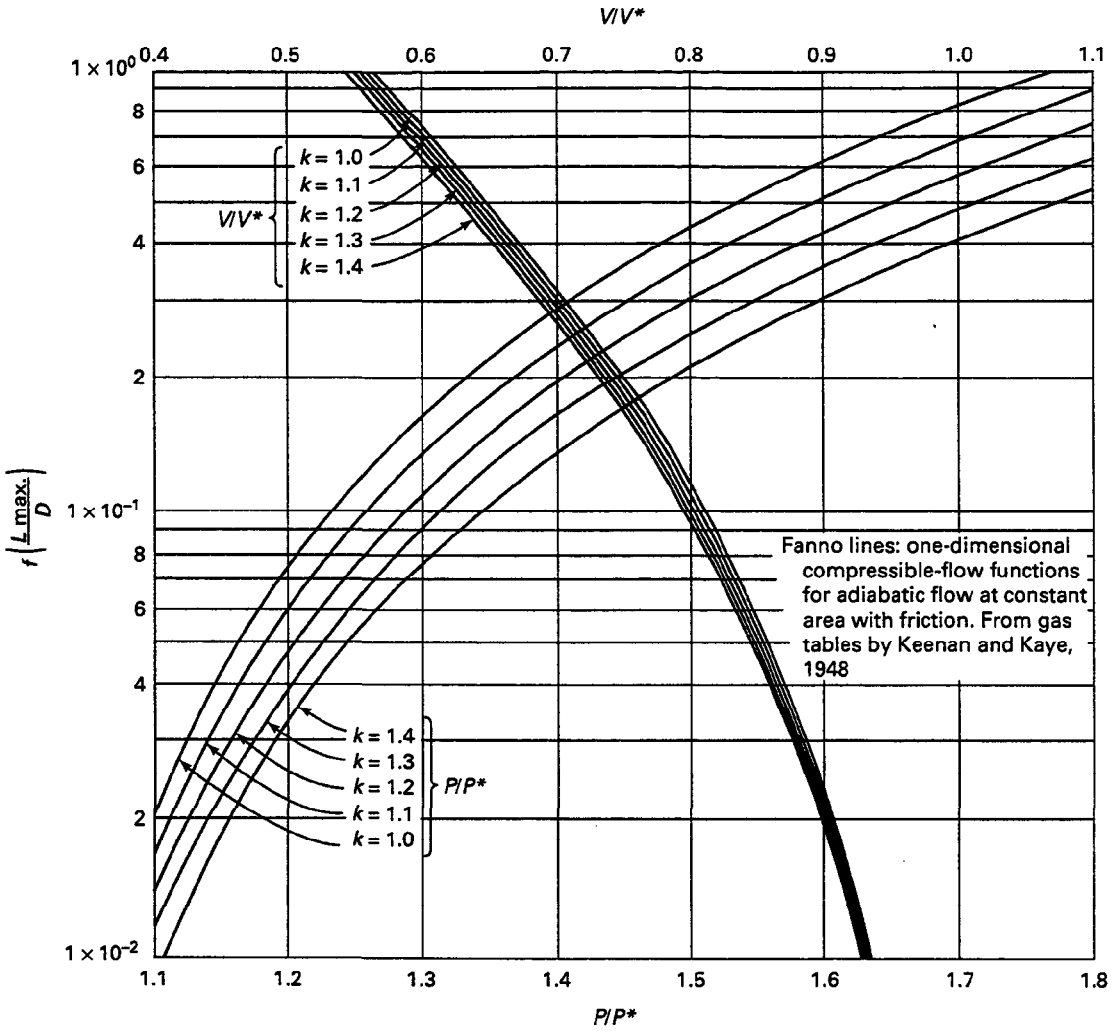

CHART II-1

$$F_1 = \frac{W}{g_c} V_1 + (P_1 - P_a) A_1$$

where

F_1 = reaction force, lbf at Point 1
W = mass flow rate, (relieving capacity stamped on the valve × 1.11), lbm/sec
g_c = gravitational constant
= 32.2 lbm-ft/lbf-sec^2
V_1 = exit velocity at Point 1, ft/sec
P_1 = static pressure at Point 1, psia
A_1 = exit flow area at Point 1, in.^{2}
P_a = atmospheric pressure, psia

To insure consideration of the effects of the suddenly applied load F, a dynamic load factor DLF should be applied (see para. II-3.5.1.3).

The methods for calculating the velocities and pressures at the exit point of the discharge elbow are the same as those discussed in para. II-2.2 of this Appendix.

II-2.3.1.2 Vent Pipe. Figure II-2-2 shows the external forces resulting from a safety valve discharge, which act on the vent pipe. The methods for calculating F_2 and F_3 are the same as those previously described. The vent pipe anchor and restraint system must be capable of taking the moments caused by these two forces, and also be capable of sustaining the unbalanced forces in the vertical and horizontal directions.

A bevel of the vent pipe will result in a flow that is not vertical. The equations shown are based on vertical flow. To take account for the effect of a bevel at the exit, the exit force will act at an angle ϕ, with

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:46 2005

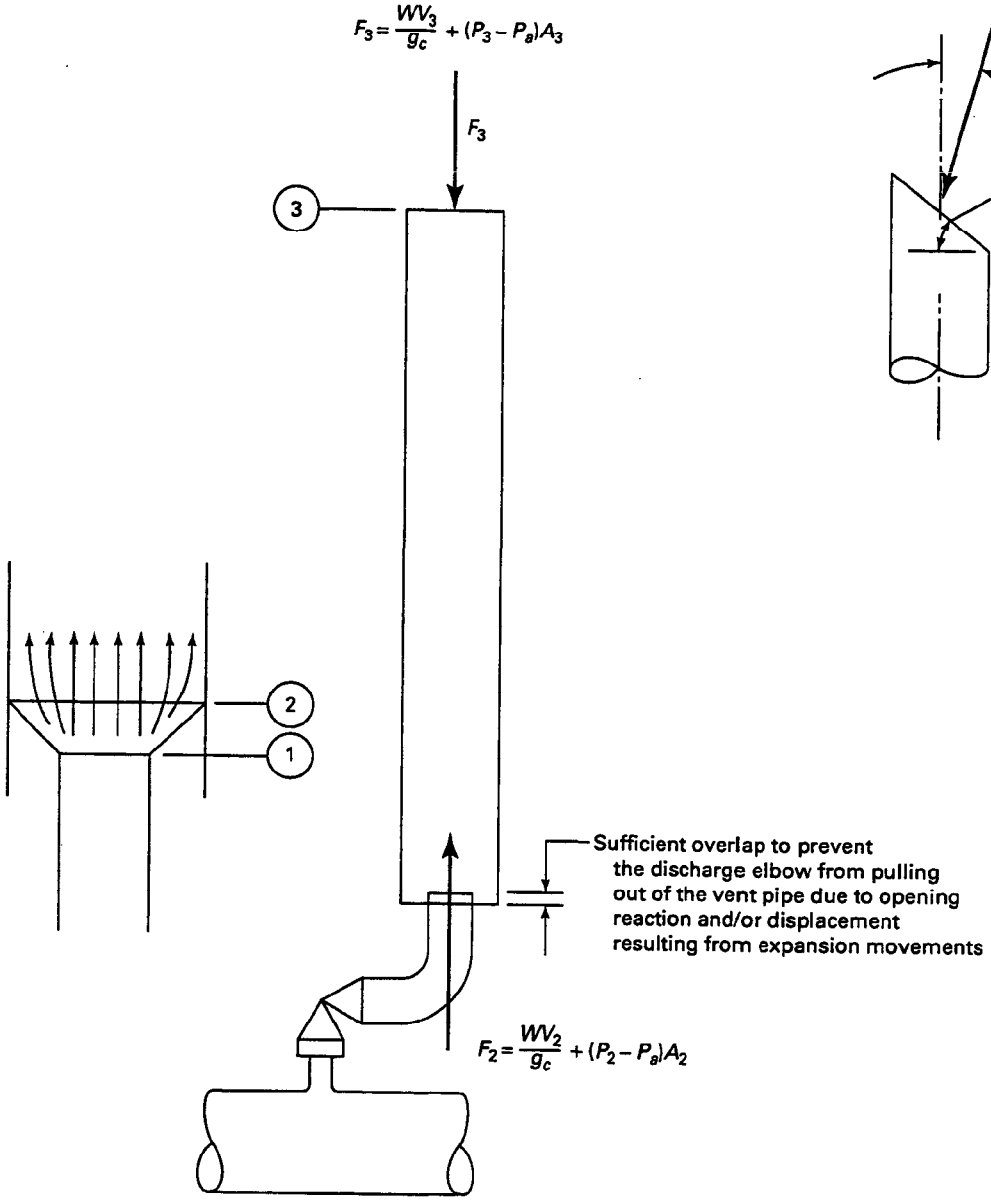

FIG. II-2-2

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:47 2005

the axis of the vent pipe discharge which is a function of the bevel angle θ. The beveled top of the vent deflects the jet approximately 30 deg off the vertical for a 60 deg bevel, and this will introduce a horizontal component force on the vent pipe systems.

The terms in the equations shown on Fig. II-2-2 are the same as those defined in para. II-2.3.1. above.

The vent pipe must be sized so that no steam is blown back at the vent line entrance. The criteria which may be used as a guide to prevent this condition are listed below.

$$\frac{W(V_1 - V_2)}{g_c} > (P_2 - P_a)A_2 - (P_1 - P_a)A_1$$

P_a = standard atmospheric pressure, psia
W = mass flow rate, lbm/sec
V = velocity, ft/sec
P_1, P_2 = local absolute pressure, psia
A = area, in.^{2}
g_c = gravitational constant
= 32.2 lbm-ft/lbf-sec^2

The inequality states that the momentum at Point 1 has to be greater than the momentum at Point 2 in order that air is educted into the vent pipe. If the momentum at Point 1 equalled the momentum at Point 2, no air would be educted into the vent pipe. If the momentum at Point 1 was less than the momentum at Point 2, steam would "blow back" from the vent pipe.

The educting effect of the vent pipe is especially important for indoor installation of safety valves. The steam being vented from the upper body during safety valve operation will be removed from the area through the vent pipe. For that reason, the fluid momentum at 1 should exceed the fluid momentum at 2, not just be equal.

If this inequality is satisfied, "blow back" will not occur. The pressures and velocities are those calculated in para. II-2.2.1.

II-2.3.2 Reaction Forces with Closed Discharge Systems. When safety valves discharge a closed piping system, the forces acting on the piping system under steady state flow will be self-equilibrated, and do not create significant bending moments on the piping system. The large steady state force will act only at the point of discharge, and the magnitude of this force may be determined as described for open discharge systems.

Relief valves discharging into an enclosed piping system create momentary unbalanced forces which act on the piping system during the first few milliseconds following relief valve lift. The pressure waves traveling through the piping system following the rapid opening of the safety valve will cause bending moments in the safety valve discharge piping and throughout the remainder of the piping system. In such a case, the designer must compute the magnitude of the loads, and perform appropriate evaluation of their effects.

II-2.4 Other Mechanical Loads

Other design mechanical loads that must be considered by the piping designer include the following:

II-2.4.1 Interaction loads on the pipe run when more than one valve opens.

II-2.4.2 Loads due to earthquake and/or piping system vibration (see para. II-3.4).

II-3.0 BENDING MOMENT COMPUTATIONS

II-3.1 General

One of the most important considerations related to the mechanical design and analysis of safety valve installation is the identification and calculation of the moments at critical points in the installation. If the bending moments are not properly calculated, it will not be possible to meet the loading and stress criteria contained in ASME B31.1. As a minimum, the following loads, previously discussed in para. II-2.0 of this Appendix, should be considered in determining these moments:

(1) thermal expansion
(2) dead weight
(3) earthquake
(4) reaction force from valve discharge
(5) other mechanical loads

The analysis of the safety valve installation should include all critical sections, such as intersection points, elbows, transition sections, etc., and any related piping, vessels, and their supports which may interact with the safety valve installation. It is often most appropriate to model the safety valve installation and its related piping as a lumped mass system joined by straight or curved elements.

II-3.2 Thermal Expansion Analysis

There are many standard and acceptable methods for determination of moments due to thermal expansion of the piping installation. The thermal expansion analysis must comply with the requirements in para. 119. The

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:47 2005

safety valve installation often presents a special problem in that there may be a variety of operational modes to consider where each mode represents a different combination of temperatures in various sections of the piping system. The design condition shall be selected so that none of the operational modes represents a condition that gives thermal expansion bending moments greater than the design condition.

The design of the safety valve installation should consider the differential thermal growth and expansion loads, as well as the local effects of reinforcing and supports. The design should also consider the differential thermal growth and expansion loads existing after any combination of safety valves (one valve to all valves) operates, raising the temperature of the discharge piping.

II-3.3 Dead Weight Analysis

The methods used for determination of bending moments due to dead weight in a safety valve installation are not different from the methods used in any other piping installation. If the support system meets the requirements in para. 121, the bending moments due to dead weight may be assumed to be $1500Z$ (in.-lb) where Z is the section modulus (in.^{3}) of the pipe or fitting being considered. However, bending moments due to dead weight are easily determined and should always be calculated in systems where stresses exceed 90% of the allowable stress limits in meeting the requirements of Eqs. (11) and (12) of para. 104.8.

II-3.4 Earthquake Analysis

Seismic loads must be known in order to calculate bending moments at critical points in the safety valve installation. If a design specification exists, it should stipulate if the piping system must be designed for earthquake. If so, it should specify the magnitude of the earthquake, the plant conditions under which the earthquake is assumed to occur, and the type earthquake analysis to be used (equivalent static or dynamic). If a design specification does not exist, it is the responsibility of the designer to determine what consideration must be given to earthquake analysis. It is beyond the scope of this Appendix to provide rules for calculating moments due to earthquake. The literature contains satisfactory references for determining moments by use of static seismic coefficients and how to perform more sophisticated dynamic analyses of the piping system using inputs in such form as time histories of displacement, velocity, and acceleration or response spectra where displacement, velocity, or acceleration is presented as a function of frequency.

Two types of seismic bending moments occur. One type is due to inertia effects and the other type is due to seismic motions of pipe anchors and other attachments. As will be shown later, the moments due to inertia effects must be considered in Eq. (12), para. 104.8, in the kS_h category. Moments due to seismic motions of the attachments may be combined with thermal expansion stress and considered in Eq. (13), para. 104.8 in the S_A category. For this reason, it may sometimes be justified for the designer to consider the moments separately; otherwise both sets of moments would have to be included in the kS_h category.

II-3.5 Analysis for Reaction Forces due to Valve Discharge

II-3.5.1 Open Discharge Systems

II-3.5.1.1 The moments due to valve reaction forces may be calculated by simply multiplying the force, calculated as described in para. II-2.3.1.1, times the distance from the point in the piping system being analyzed, times a suitable dynamic load factor. In no case shall the reaction moment used in para. II-4.2 at the branch connection below the valve be taken at less than the product of

$$(DLF)\ (F_1)\ (D)$$

where

F_1 = force calculated per para. II-2.3.1.1
D = nominal O.D. of inlet pipe
DLF = dynamic load factor (see para. II-3.5.1.3)

Reaction force and resultant moment effects on the header, supports, and nozzles for each valve or combination of valves blowing shall be considered.

II-3.5.1.2 Multiple Valve Arrangements. Reaction force and moment effects on the run pipe, header, supports, vessel, and connecting nozzles for each valve blowing, and when appropriate, for combinations of valves blowing should be considered. In multiple valve arrangements, each valve will open at a different time, and since all valves may not be required to open during an overpressure transient, several possible combinations of forces can exist. It may be desirable to vary the direction of discharge of several safety valves on the same header to reduce the maximum possible forces when all valves are blowing.

II-3.5.1.3 Dynamic Amplification of Reaction Forces. In a piping system acted upon by time varying loads, the internal forces and moments are generally greater than those produced under static application of

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:47 2005

the load. This amplification is often expressed as the dynamic load factor *DLF* and is defined as the maximum ratio of the dynamic deflection at any time to the deflection which would have resulted from the static application of the load. For structures having essentially one degree-of-freedom and a single load application, the *DLF* value will range between one and two depending on the time-history of the applied load and the natural frequency of the structure. If the run pipe is rigidly supported, the safety valve installation can be idealized as a one degree-of-freedom system and the time-history of the applied loads can often be assumed to be a single ramp function between the no-load and steady state condition. In this case the *DLF* may be determined in the following manner.

(1) Calculate the safety valve installation period T using the following equation and Fig. II-3-1.

$$T = 0.1846 \sqrt{\frac{Wh^3}{EI}}$$

where

T = safety valve installation period, sec
W = weight of safety valve, installation piping, flanges, attachments, etc., lb
h = distance from run pipe to center line of outlet piping, in.
E = Young's modulus of inlet pipe, lb/in.^{2}, at design temperature
I = moment of inertia of inlet pipe, in.^{4}

(2) Calculate ratio of safety valve opening time to installation period (t_o/T) where t_o is the time the safety valve takes to go from fully closed to fully open, sec, and T is determined in (1) above.

(3) Enter Fig. II-3-2 with the ratio of safety valve opening time to installation period and read the *DLF* from the ordinate. The *DLF* shall never be taken less than 1.1.

If a less conservative *DLF* is used, the *DLF* shall be determined by calculation or test.

II-3.5.1.4 Valve Cycling. Often, safety valves are full lift, pop-type valves, and are essentially full-flow devices, with no capability for flow modulation. In actual pressure transients, the steam flow required to prevent overpressure is a varying quantity, from zero to the full rated capacity of the safety valves. As a result, the valves may be required to open and close a number of times during the transient. Since each opening and closing produces a reaction force, consideration should be given to the effects of multiple valve operations on the piping system, including supports.

II-3.5.1.5 Time-History Analysis. The reaction force effects are dynamic in nature. A time-history dynamic solution, incorporating a multidegree of freedom lumped mass model solved for the transient hydraulic forces is considered to be more accurate than the form of analysis presented in this Appendix.

II-3.5.2 Closed Discharge Systems. Closed discharge systems do not easily lend themselves to simplified analysis techniques. The discussions on pressure in para. II-2.2.2 and on forces in para. II-2.3.2 indicate that a time-history analysis of the piping system may be required to achieve realistic values of moments.

II-3.5.3 Water Seals. To reduce the problem of steam or gas leakage through the safety valve seats, the valve inlet piping may be shaped to form a water seal below each valve seat. If the valves are required to open to prevent overpressure, the water from the seal is discharged ahead of the steam as the valve disk lifts. The subsequent flow of water and steam through the discharge piping produces a significant pressure and momentum transient. Each straight run of discharge piping experiences a resulting force cycle as the water mass moves from one end of the run to the other.

For most plants which employ water seals, only the first cycle of each occurrence has a force transient based on water in the seal. The remaining cycles of each occurrence would be based on steam occupying the seal piping, and the transient forces would be reduced in magnitude.

II-4.0 LOADING CRITERIA AND STRESS COMPUTATION

II-4.1

All critical points in the safety valve installation shall meet the following loading criteria.

$$S_{lp} + S_{SL} \le S_h \quad (1)$$

$$S_{lp} + S_{SL} + S_{OL} \le kS_h \quad (2)$$

$$S_{lp} + S_{SL} + S_E \le S_A + S_h \quad (3)$$

where

S_{lp} = longitudinal pressure stress
S_{SL} = bending stresses due to sustained loads, such as dead weight

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:48 2005

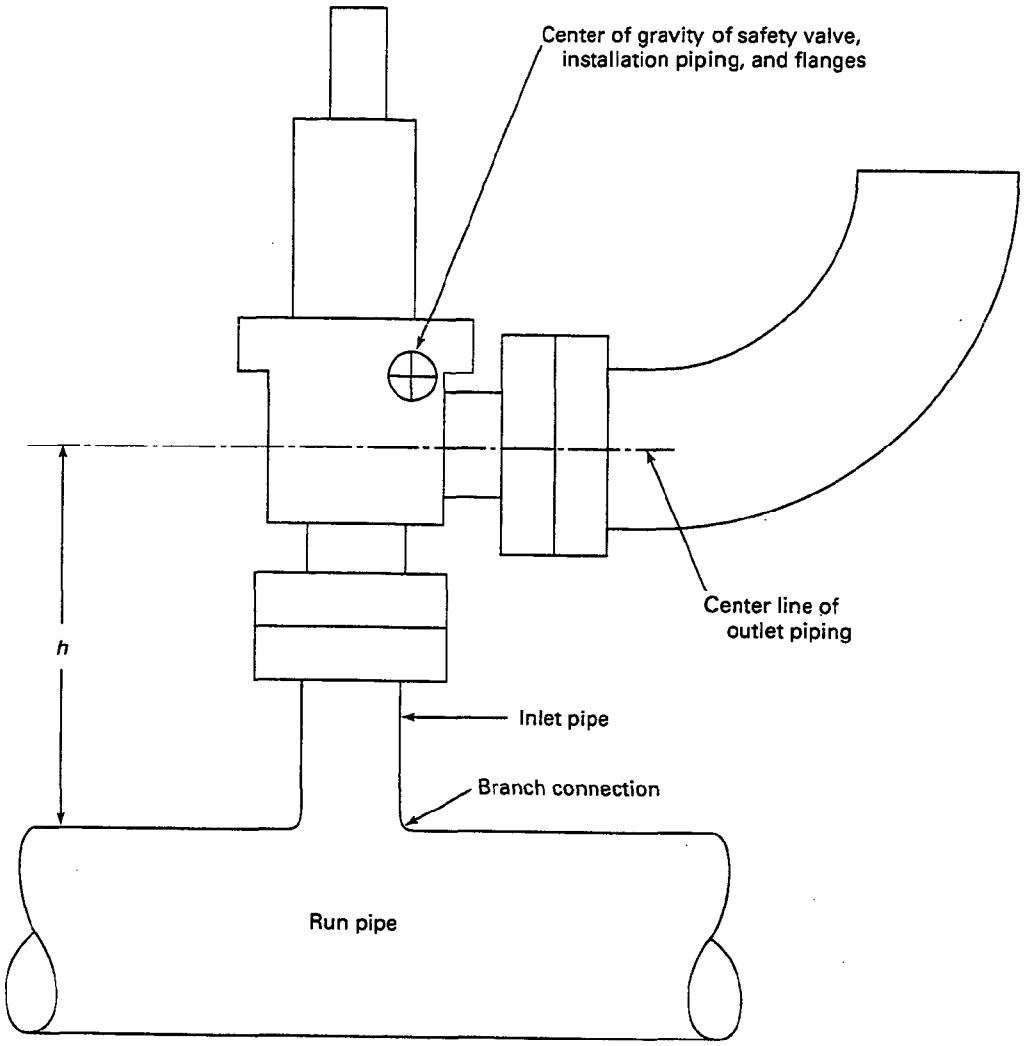

FIG. II-3-1 SAFETY VALVE INSTALLATION (OPEN DISCHARGE SYSTEM)

S_{OL} = bending stresses due to occasional loads, such as earthquake, reaction from safety valve discharge and impact loads

S_E = bending stresses due to thermal expansion

S_h, k, and S_A are as defined in ASME B31.1

The three loading criteria defined above are represented by Eqs. (11) and (12) in para. 104.8.

II-4.2 Stress Calculations

II-4.2.1 Pressure Stresses. The Code does not require determination of the pressure stresses that could cause failure of the pressure containing membrane. Instead, the Code provides rules to insure that sufficient wall thickness is provided to prevent failures due to pressure. It is not necessary to repeat these rules in this Appendix; however, some of the more important are listed below for reference.

(1) All pipe (plus other components) must satisfy the minimum required wall thickness of Eq. (3) of para. 104.1.2. In addition, wall thickness must be adequate to satisfy Eqs. (11) and (12) in para. 104.8. These two equations may govern determination of wall thickness in low pressure systems.

(2) No minimum wall thickness calculations are needed for components purchased to approved standards in Table 126.1.

(3) Pipe bends must meet the requirements of (1) above *after* bending.

GENERAL NOTE: This figure is based on curves from *Introduction to Structural Dynamics,* J. M. Biggs, McGraw-Hill Book Co., 1964.

FIG. II-3-2 DYNAMIC LOAD FACTORS FOR OPEN DISCHARGE SYSTEM
This Figure Is Based on Curves From *Introduction to Structural Dynamics,* J. M. Biggs, McGraw-Hill Book Co., 1964

(4) Branch connections which do not meet the requirements of (2) above must meet the area replacement requirements of para. 104.3.

II-4.2.2 Pressure Plus Bending Stresses. In order to guard against membrane failures (catastrophic), prevent fatigue (leak) failures, and to assure shakedown, the equations in para. 104.8 must be satisfied. These equations apply to all components in the safety valve installation and will not be repeated here. However, some additional explanation of these equations in regard to the very critical points upstream of the safety valve are in the paragraphs below.

II-4.2.2.1 Additive Stresses at Branch Connection. For purposes of Eqs. (11), (12), and (13) in para. 104.8 the section modulus and moments for application to branch connections, such as safety valve inlet pipes, are:

(1) For branch connections the Z should be the effective section modulus for the branch as defined in para. 104.8.

Thus,

$$Z = Z_b = \pi r_b^2 t_s \text{ (effective section modulus)}$$

where

r_b = mean branch cross-sectional radius, in.
t_s = lesser of t_r and it_b where
t_r = nominal thickness of run pipe
i = the branch connection stress intensification factor

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:49 2005

t_b = nominal thickness of branch pipe

(2) Moment terms shall be defined as follows:

$$M_B = \sqrt{M_{x3}^2 + M_{y3}^2 + M_{z3}^2}$$

where M_B, M_{x3}, M_{y3}, and M_{z3} are defined in para. 104.8.

(3) Where the D_o/t_n of the branch connection differs from the D_o/t_n header or run, the larger of the two D_o/t_n values should be used in the first term of Eqs. (11) and (12) where D_o and t_n are defined in paras. 104.1 and 104.8, respectively.

II-4.2.2.2 Additive Stresses in Inlet Pipe. Equations (11), (12), and (13) in para. 104.8 may be applied to the inlet pipe in the same manner as described above for the branch connection, except that the values for D_o/t_n and Z should be for the inlet pipe and the stress intensification factor used will be different. It should be noted that the values D_o, t_n, and Z should be taken from a point on the inlet pipe such that D_o/t_n will have a maximum and Z a minimum value for the inlet pipe.

II-4.2.3 Analysis of Flange. It is important that the moments from the various loading conditions described in para. II-4.2.2 do not overload the flanges on the safety valve inlet and outlet. One method of doing this is to convert the moments into an equivalent pressure that is then added to the internal pressure. The sum of these two pressures P_{FD} would be acceptable if either of the following criteria are met.

(1) P_{FD} does not exceed the ASME B16.5 flange rating.

(2) S_H, S_R, and S_T should be less than the yield stress at design temperature, where S_H, S_R, and S_T are as defined in 2-7 of ASME Section VIII, Division 1 with these exceptions.

(A) P_{FD} should be used in the ASME Section VIII, Division 1 equations instead of the design pressure.

(B) S_H should include the longitudinal pressure stress at the flange hub.

II-4.2.4 Analysis of Valve. The allowable forces and moments which the piping system may place on the safety valves must be determined from the valve manufacturer. In some cases, the valve flanges are limiting rather than the valve body.

II-5.0 DESIGN CONSIDERATIONS

II-5.1 General

The design of safety valve installations shall be in accordance with para. 104 except that consideration be given to the rules provided in the following subparagraphs. These rules are particularly concerned with that portion of the piping system attached to and between the safety valve and the run pipe, header, or vessel which the valve services and includes the branch connection to the run pipe, header, or vessel.

II-5.2 Geometry

II-5.2.1 Locations of Safety Valve Installations. Safety valve installations should be located at least eight pipe diameters (based on I.D.) downstream from any bend in a high velocity steam line to help prevent sonic vibrations. This distance should be increased if the direction of the change of the steam flow is from vertical upwards to horizontal in such a manner as to increase density of the flow in the area directly beneath the station nozzles. Similarly, safety valve installation should not be located closer than eight pipe diameters (based on I.D.) either upstream or downstream from fittings.

II-5.2.2 Spacing of Safety Valve Installation. Spacing of safety valve installations must meet the requirements in Note (6)(c), Appendix D, Table D-1.

II-5.3 Types of Valves and Installations

II-5.3.1 Installations With Single Outlet Valves. Locate unsupported valves as close to the run pipe or header as is physically possible to minimize reaction moment effects.

Orientation of valve outlet should preferably be parallel to the longitudinal axis of the run pipe or header.

Angular discharge elbows oriented to minimize the reaction force moment shall have a straight pipe of at least one pipe diameter provided on the end of the elbow to assure that the reaction force is developed at the desired angle. Cut the discharge pipe square with the center line. Fabrication tolerances, realistic field erection tolerances, and reaction force angle tolerances must be considered when evaluating the magnitude of the reaction moment.

The length of unsupported discharge piping between the valve outlet and the first outlet elbow [Fig. II-1-2(A), distance *l*] should be as short as practical to minimize reaction moment effects.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:49 2005

II-5.3.2 Installations with Double Outlet Valves. Double outlet valves with symmetrical tail-pipes and vent stacks will eliminate the bending moment in the nozzle and the run pipe or header providing there is equal and steady flow from each outlet. If equal flow cannot be guaranteed, the bending moment due to the unbalanced flow must be considered. Thrust loads must also be considered.

II-5.3.3 Multiple Installations. The effects of the discharge of multiple safety valves on the same header shall be such as to tend to balance one another for all modes of operation.

II-5.4 Installation Branch Connections

Standard branch connections shall as a minimum meet the requirements of para. 104.3. It should be noted that branch connections on headers frequently do not have sufficient reinforcement when used as a connection for a safety valve. It may be necessary to provide additional reinforcing (weld deposit buildup) or special headers that will satisfactorily withstand the reaction moments applied.

Material used for the branch connection and its reinforcement shall be the same or of higher strength than that of the run pipe or header.

It is strongly recommended that branch connections intersect the run pipe or header normal to the surface of the run pipe or header at $\alpha = 90$ deg, where α is defined as the angle between the longitudinal axis of the branch connection and the normal surface of the run pipe or header. Branch connections that intersect the run pipe or headers at angles,

$$90 \text{ deg} > \alpha \geq 45 \text{ deg}$$

should be avoided. Branch connections should not in any case intersect the run pipe or header at angles,

$$\alpha < 45 \text{ deg}$$

II-5.5 Water in Installation Piping

II-5.5.1 Drainage of Discharge Piping. Drains shall be provided so that condensed leakage, rain, or other water sources will not collect on the discharge side of the valve and adversely affect the reaction force. Safety valves are generally provided with drain plugs that can be used for a drain connection. Discharge piping shall be sloped and provided with adequate drains if low points are unavoidable in the layout.

II-5.5.2 Water Seals. Where water seals are used ahead of the safety valve, the total water volume in the seals shall be minimized. To minimize forces due to slug flow or water seal excursion, the number of changes of direction and the lengths of straight runs of installation piping shall be limited. The use of short radius elbows is also discouraged; the pressure differential across the cross section is a function of the elbow radius.

II-5.6 Discharge Stacks

If telescopic or uncoupled discharge stacks, or equivalent arrangements, are used then care should be taken to insure that forces on the stack are not transmitted to the valve discharge elbow. Stack clearances shall be checked for interference from thermal expansion, earthquake displacements, etc. Discharge stacks shall be supported adequately for the forces resulting from valve discharge so that the stack is not deflected, allowing steam to escape in the vicinity of the valve. In addition, the deflection of the safety valve discharge nozzle (elbow) and the associated piping system when subjected to the reaction force of the blowing valve shall be calculated. This deflection shall be considered in the design of the discharge stacks slip-joint to assure that the discharge nozzle remains in the stack, preventing steam from escaping in the vicinity of the valve.

To prevent blowback of discharging steam from inlet end of vent stack, consider the use of an antiblowback device that still permits thermal movements of header.

II-5.7 Support Design

Supports provided for safety valves and the associated piping require analysis to determine their role in restraint as well as support. These analyses shall consider at least the following effects:

(A) differential thermal expansion of the associated piping, headers, and vessels;

(B) dynamic response characteristics of the support in relation to the equipment being supported and the structure to which it is attached, during seismic events and valve operation. Maximum relative motions of various portions of the building and structures to which supports are attached resulting from seismic excitation must be considered in selecting, locating, and analyzing support systems.

(C) capability of the support to provide or not provide torsional rigidity, per the support design requirements.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:49 2005

II-5.7.1 Pipe Supports. Where necessary, it is recommended that the support near the valve discharge be connected to the run pipe, header, or vessel rather than to adjacent structures in order to minimize differential thermal expansion and seismic interactions.

Each straight leg of discharge piping should have a support to take the force along that leg. If the support is not on the leg itself, it should be as near as possible on an adjacent leg.

When a large portion of the system lies in a plane, the piping if possible should be supported normal to that plane even though static calculations do not identify a direct force requiring restraint in that direction. Dynamic analyses of these systems have shown that out-of-plane motions can occur.

II-5.7.2 Snubbers. Snubbers are often used to provide a support or a stop against a rapidly applied load, such as the reaction force of a blowing valve or the pressure-momentum transient in a closed piping system. Since snubbers generally displace a small distance before becoming rigid, the displacement must be considered in the analysis. In addition, if the load is applied to the snubber for a relatively long time, the snubber performance characteristics shall be reviewed to assure that the snubber will not permit motion during the time period of interest, or the additional displacement must be considered in the analysis. The snubber performance shall also be reviewed for response to repetitive load applications caused by the safety valve cycling open and closed several times during a pressure transient.

II-5.8 Silencer Installation

Silencers are occasionally installed on safety valve discharges to dissipate the noise generated by the sonic velocity attained by the fluid flowing through the valve.

Silencers must be properly sized to avoid excessive backpressure on the safety valve causing improper valve action or reducing relieving capacity.

Safety valve discharge piping, silencers, and vent stacks shall be properly supported to avoid excessive loading on the valve discharge flange.

II-6.0 SAMPLE DESIGNS

Examples of various safety valve installations that a designer may encounter in practice are presented in Figs. II-1-2(A) and II-6-1.

II-7.0 SAMPLE PROBLEM (SEE FIGS. II-7-1 AND II-7-2)

II-7.1 Procedure

(1) Determine pressure and velocity at discharge elbow exit.

(2) Calculate maximum operating pressure for discharge exit.

(3) Calculate reaction force at discharge elbow exit.

(4) Calculate bending moments of Points (1) and (2) from reaction force and seismic motion.

(5) Determine stress intensification factors at Points (1) and (2).

(6) Calculate predicted stresses at Points (1) and (2) and compare with allowable stress.

(7) Calculate maximum operating pressure for vent pipe.

(8) Check for blowback.

(9) Calculate forces and moments on vent pipe.

(1) Pressure and Velocity at Discharge Elbow Exit (Para. II-2.2.1)

$$P_1 = \frac{W}{A_1}\frac{(b-1)}{b}\sqrt{\frac{2(h_o - a)J}{g_c(2b-1)}}$$

$$V_1 = \sqrt{\frac{2g_c J(h_o - a)}{(2b-1)}}$$

W = flow rate
= 116.38 lbm/sec
A_1 = 50.03 in.^{2}
h_o = stagnation enthalpy for steam at 925 psia, 1000°F
= 1507.3 Btu/lbm
a = 823 Btu/lbm for $15 \le P_1 \le 1000$ psia and $h_o \le 1600$ Btu/lbm
b = 4.33 for $15 \le P_1 \le 1000$ psia and $h_o \le 1600$ Btu/lbm
J = 778 ft-lbf/Btu
g_c = 32.2 lbm-ft/lbf-sec^2
P_1 = 118 psia
V_1 = 2116 ft/sec

(2) Discharge Elbow Maximum Operating Pressure

L/D for 8 in. Class 150 ASME weld neck flange

$$i = 1.5 \left(\frac{R_m}{T_r}\right)^{2/3} \left(\frac{r'_m}{R_m}\right)^{1/2} \left(\frac{T'_b}{T_r}\right) \left(\frac{r'_m}{r_p}\right)$$

R_m, T_r, r'_m, T'_b, and r_p are shown in sketch below:

$$i_{(1)} = 1.5 \left(\frac{15.375}{2.5}\right)^{2/3} \left(\frac{4.25}{15.375}\right)^{1/2} \left(\frac{2.5}{2.5}\right) \left(\frac{4.25}{5.5}\right)$$

$$i_{(1)} = 2.05$$

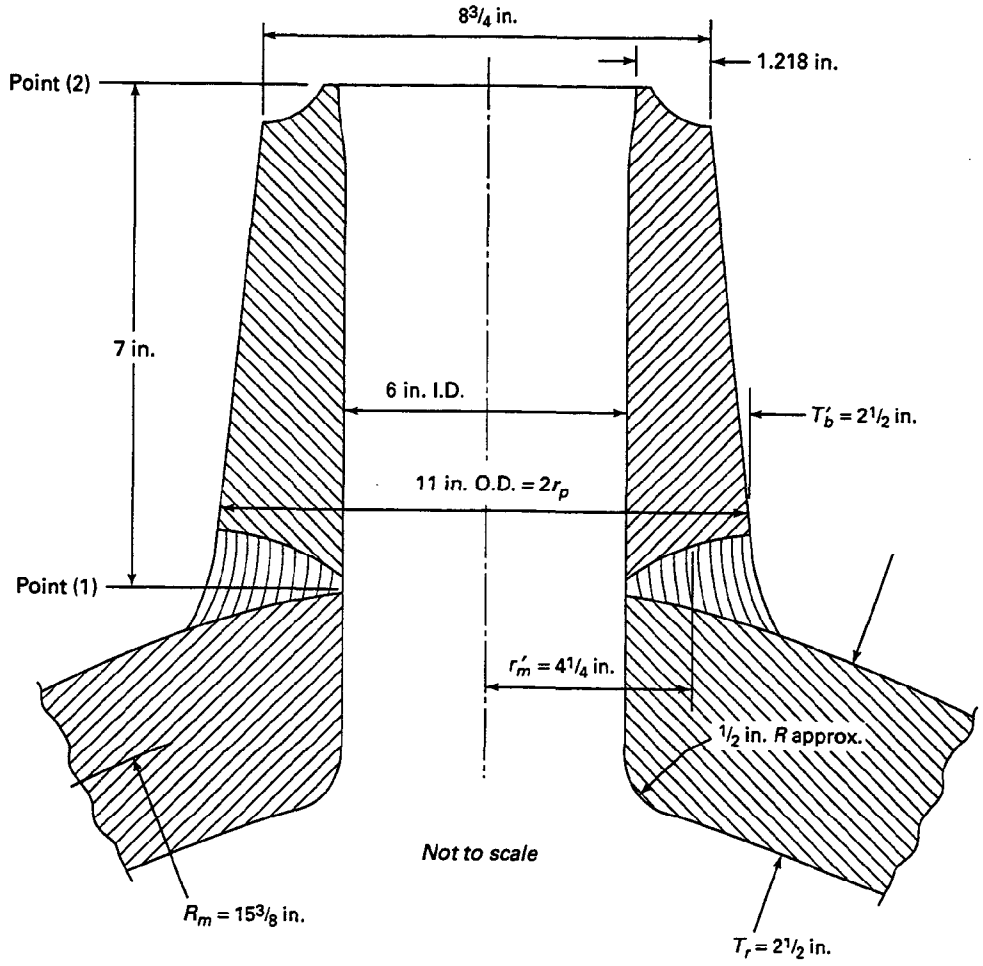

FIG. II-7-2

$$(P_1 - P_a) = 118 - 15$$
$$= 103 \text{ psig}$$
$$WV_1/g_c = 7648 \text{ lbf}$$
$$(P_1 - P_a)\, A_1 = 5153 \text{ lbf}$$
$$F_1 = 12{,}801 \text{ lbf}$$

(4) Bending Moments at Points (1) and (2)

(A) Bending Moment at Points (1) and (2) due to Reaction at Point (1):

$$M_{1(1)} = M_{1(2)}$$
$$= F_1 \times L \times DLF$$
$$L = \text{moment arm}$$
$$= 24 \text{ in.}$$

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:50 2005

DLF = dynamic load factor

To determine DLF, first determine the safety valve installation period T:

$$T = 0.1846 \sqrt{\frac{Wh^3}{EI}}$$

where

W = weight of valve
= 800 lb
h = distance from run pipe to center line of outlet piping
= 19 in.
E = Young's modulus of inlet pipe at design temperature
= 23×10^6 psi
I = moment of inertia of inlet pipe
= $\frac{\pi}{64}(D_o^4 - D_i^4)$
Use average O.D. and I.D. to determine I.
D_o = 9.875 in. avg.; D_i = 6 in. avg.
= 403.2 in.^{4}
T = 0.00449 sec

For a valve rise time of 0.040 sec = t_o, the ratio t_o/T is 8.9. From Fig. II-3-2, DLF = 1.11.

Using F_1 = 12,801 lbf, L = 24 in., and DLF = 1.11.

$$M_{1(1)} = M_{1(2)} = 341{,}018 \text{ in.-lb}$$

(B) Bending Moments at Points (1) and (2) due to Seismic Loading

Seismic force,

$$F_S = \text{mass} \times \text{acceleration}$$

$$= \left[\frac{800 \text{ lbm}}{32.2 \text{ lbm-ft/lbf-sec}^2}\right] \times 1.5(32.2 \text{ ft/sec}^2)$$

$$= 1200 \text{ lbf}$$

Moment arm for Point (1) = 19 in.

$$M_{S(1)} = 1200 \text{ lbf (19 in.)} = 22{,}800 \text{ in.-lb}$$

Moment arm for Point (2) = 12 in.

$$M_{S(2)} = 1200 \text{ lbf (12 in.)} = 14{,}400 \text{ in.-lb}$$

(C) Combined Bending Moments at Points (1) and (2)

$$M_{(1)} = M_{1(1)} + M_{S(1)} = 363{,}819 \text{ in.-lb}$$

$$M_{(2)} = M_{1(2)} + M_{S(2)} = 355{,}419 \text{ in.-lb}$$

(5) Stress Intensification Factors at Points (1) and (2)

(A) At Point (1), Branch Connection

$$i_{(1)} = 2.05$$

(B) Stress Intensification Factors at Point (2), Buttweld

$$i_{(2)} = 1.0$$

(6) Predicted Stresses at Points (1) and (2)

(A) Predicted Stresses at Point (1), Branch Connection

$$\text{Predicted stress} = \frac{PD_o}{4t_n}$$

$$\frac{D_o}{t_n} \text{ for run pipe} = \frac{33.25 \text{ in.}}{2.5 \text{ in.}} = 13.3$$

$$\frac{D_o}{t_n} \text{ for branch pipe} = \frac{11 \text{ in.}}{2.5 \text{ in.}} = 4.4$$

Use larger value with P = 910 psig.

$$\text{Pressure stress}_{(1)} = 3030 \text{ psi}$$

$$\text{Flexure stress}_{(1)} = \frac{0.75i\,M_{(1)}}{Z_{(1)}}$$

$$Z_{(1)} = \pi r_b^2 t_s$$

t_S = lesser of t_r or $(i)\,t_b$

t_R = 2.5 in.; $(i)\,t_b$ = (2.05) 2.5 in.

t_S = 2.5 in.

r_b = 4.25 in.

$Z_{(1)}$ = 142 in.^{3}

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:51 2005

$$i_{(1)} = 2.05;\ M_{(1)} = 363{,}819 \text{ in.-lb}$$

$$\text{Flexure stress}_{(1)} = 3939 \text{ psi}$$

$$\text{Combined stress}_{(1)} = \text{pressure stress}_{(1)} + \text{flexure stress}_{(1)} = 6969 \text{ psi}$$

(B) Predicted Stresses at Point (2), Buttweld

$$\text{Pressure stress} = \frac{P\,D_o}{4\,t_n}$$

$$P = 910 \text{ psig}$$

$$D_o = 8.75 \text{ in.}$$

$$t_n = 1.218 \text{ in.}$$

$$\text{Pressure stress}_{(2)} = 1635 \text{ psi}$$

$$\text{Flexure stress}_{(2)} = \frac{0.75\,i\,M_{(2)}}{Z_{(2)}}$$

$$Z_{(2)} = \frac{\pi}{32}\,\frac{D_o^4 - D_i^4}{D_o}$$

$$D_o = 8.75 \text{ in.}$$

$$D_i = 6 \text{ in.}$$

$$Z_{(2)} = 51.1 \text{ in.}^3$$

$$i_{(2)} = 1.0$$

$$M_{(2)} = 355{,}419 \text{ in.-lb}$$

$$\text{Flexure stress}_{(2)} = 6955 \text{ psi}$$

(Note that $0.75i$ is set equal to 1.0 whenever $0.75i$ is less than 1.0, as in this case.)

$$\text{Combined stress}_{(2)} = \text{pressure stress}_{(2)} + \text{flexure stress}_{(2)} = 8590 \text{ psi}$$

(C) Comparison of Predicted Stress with Allowable Stress. Allowable stress of nozzle material at 1000°F is

$$S_h = 7800 \text{ psi}$$

$$k = 1.2$$

$$kS_h = 9360 \text{ psi}$$

$$\text{Combined stress}_{(1)} = 6969 \text{ psi}$$

$$\text{Combined stress}_{(2)} = 8590 \text{ psi}$$

(7) Calculate the Maximum Operating Pressure for Vent Pipe

$$P_3 = P_1\left(\frac{A_1}{A_3}\right) = 118 \text{ psia}\left(\frac{50.03 \text{ in.}^2}{114.80 \text{ in.}^2}\right)$$

$$= 51.4 \text{ psia}$$

L/D for 20 ft 0 in. of 12 in. SCH 30 pipe = 19.85.

$$\Sigma(L/D) = \left(\frac{L_{\max.}}{D}\right) = 19.85$$

$$f = 0.013$$

$$k = 1.3$$

$$f\left(\frac{L_{\max.}}{D}\right) = 0.258$$

From Chart II-1, $P/P^* = 1.506$.

$$P_2 = P_3\,(P/P^*) = 77.4 \text{ psia}$$

(8) Check for Blowback From Vent Pipe. Calculate the velocity V_2 that exists at the inlet to the vent pipe (para. II-2.2.1.4).

$$f\left(\frac{L_{\max.}}{D}\right) = 0.258 \text{ from Step (7)}$$

$$V_3 = V_1 = 2116 \text{ ft/sec}$$

From Chart II-1, $V/V^* = 0.7120$.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:51 2005

$$V_2 = V_3 (V/V^*) = 1507 \text{ ft/sec}$$

Check the inequality from para. II-2.3.1.2.

$$\frac{W (V_1 - V_2)}{g_c} > (P_2 - P_a) A_2 - (P_1 - P_a) A_1$$

$$\frac{116.38 (2116 - 1507)}{32.2} > (77.4 - 14.7)(114.8) - (118 - 14.7)(50.03)$$

$$2201 > 2030$$

The inequality has been satisfied but the designer may require a design margin that would make 14 in. SCH 30 more acceptable. If a larger vent pipe is chosen, then the vent pipe analysis would have to be repeated for the 14 in. SCH 30 pipe.

(9) Calculate Forces and Moments on Vent Pipe Anchor (a)

$$F_2 = \frac{WV_2}{g_c} + (P_2 - P_a) A_2$$

$$= \frac{(116.38)(1507)}{32.2} + (77.4 - 14.7)(114.8)$$

$$= 5447 + 7198.0 = 12{,}645 \text{ lbf}$$

$$F_3 = \frac{(116.38)(2116)}{32.2} + (51.4 - 14.7)(114.8)$$

$$= 7648 + 4213 = 11{,}861 \text{ lbf}$$

Assume a 30 deg jet deflection angle for vent pipe outlet.

Vertical component of F_3

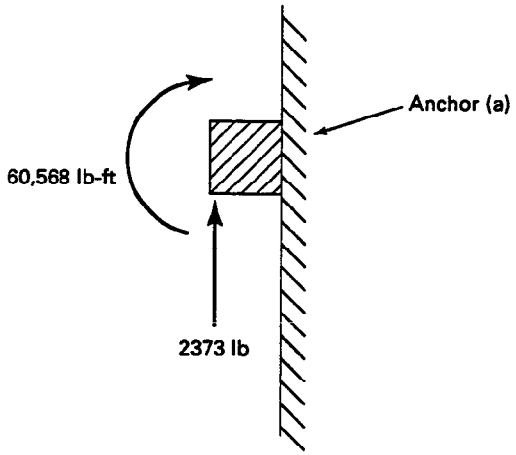

FIG. II-7-3

$$F_{3V} = F_3 \cos 30 \text{ deg} = 10{,}272 \text{ lbf}$$

Horizontal component of F_3

$$F_{3H} = F_3 \sin 30 \text{ deg} = 5931 \text{ lbf}$$

Net imbalance on the vent pipe in the vertical direction is

$$F_2 - F_{3V} = 2373 \text{ lbf}$$

Moment on vent pipe anchor

$$\Sigma M = (F_2 - F_{3V}) \frac{D_o}{2} + F_{3H} \times [\text{distance from (a) to point 3}]$$

$$= (2373)\left(\frac{1.06}{2}\right) + (5931)(10.0)$$

$$= 60{,}568 \text{ ft-lb}$$

The vent pipe anchor would then be designed for the loads shown in Fig. II-7-3 for safety valve operation.

Conclusion

Branch connection stresses at Points (1) and (2) due to seismic and relief valve discharge are within 1.2 S_h. Blowback will not occur with the 12 in. standard weight vent pipe. The vent pipe anchor loads have been identified.

NONMANDATORY APPENDIX III[1]
RULES FOR NONMETALLIC PIPING

FOREWORD

ASME B31.1 contains rules governing the design, fabrication, materials, erection, and examination of power piping systems. Experience in the application of nonmetallic materials for piping systems has shown that a number of considerations exist for the use of these materials that are not addressed in the current body of the Code. In order to address these, the requirements and recommendations for the use of nonmetallic piping (except in paras. 105.3, 108.4, 116, and 118) have been separately assembled in this nonmandatory Appendix.

III-1.0 SCOPE AND DEFINITION

III-1.1 General

III-1.1.1 This Appendix provides minimum requirements for the design, materials, fabrication, erection, testing, examination, and inspection of nonmetallic piping within the jurisdiction of the ASME B31.1 Power Piping Code. All references to the Code or to Code paragraphs in this Appendix are to the Section B31.1 Power Piping Code. In this Appendix, nonmetallic piping shall be limited to plastic and elastomerbased piping materials, with or without fabric or fibrous material added for pressure reinforcement.

III-1.1.2 Standards and specifications incorporated in this Appendix are listed in Table III-4.1.1. The effective date of these documents shall correspond to the date of this Appendix.

III-1.1.3 The provisions in Chapters I through VI and in Appendices A through F are requirements of this Appendix only when specifically referenced herein.

[1] Nonmandatory Appendices are identified by a Roman numeral; mandatory Appendices are identified by a letter. Therefore, Roman numeral I is not used in order to avoid confusion with the letter I.

III-1.2 Scope

III-1.2.1 All applicable requirements of para. 100.1 and the limitations of para. 105.3 shall be met in addition to those in this Appendix.

III-1.2.2 Use of this Appendix is limited to:

(A) water service;

(B) nonflammable and nontoxic liquid, dry material, and slurry systems;

(C) reinforced thermosetting resin pipe in buried flammable and combustible liquid service systems [refer to para. 122.7.3(F)]; and

(D) polyethylene pipe in buried flammable and combustible liquid and gas service. Refer to paras. 122.7.3(F) and 122.8.1(G).

III-1.2.3 Nonmetallic piping systems shall not be installed in a confined space where toxic gases could be produced and accumulate, either from combustion of the piping materials or from exposure to flame or elevated temperatures from fire.

III-1.3 Definitions and Abbreviations

III-1.3.1 Terms and definitions relating to plastic and other nonmetallic piping materials shall be in accordance with ASTM D 883. The following terms and definitions are in addition to those provided in the ASTM standard.

adhesive: a material designed to join two other component materials together by surface attachment (bonding)

adhesive joint: a bonded joint made using an adhesive on the surfaces to be joined

bonder: one who performs a manual or semiautomatic bonding operation

bonding operator: one who operates a machine or automatic bonding equipment

bonding procedure: the detailed methods and practices involved in the production of a bonded joint

Bonding Procedure Specification (BPS): the document that lists the parameters to be used in the construction

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:51 2005

of bonded joints in accordance with the requirements of this Code

butt-and-wrapped joint: a joint made by applying plies of reinforcement saturated with resin to the surfaces to be joined

chopped roving: a collection of noncontinuous glass strands gathered without mechanical twist. Each strand is made up of glass filaments bonded together with a finish or size for application by chopper gun

chopped strand mat: a collection of randomly oriented glass fiber strands, chopped or swirled together with a binder in the form of a blanket

continuous roving: a collection of continuous glass strands wound into a cylindrical package without mechanical twist

curing agent: a reactive material which when combined with a resin material reacts or polymerizes (cross-links) with the resin; also referred to as a hardener

diluent: a reactive modifying material, usually liquid, which reduces the concentration of a resin material to facilitate handling characteristics and improve wetting

fire retardant resin: a specially compounded material combined with a resin material designed to reduce or eliminate the tendency to burn

flexibilizer: a modifying liquid material added to a resinous mixture designed to allow the finished component the ability to be flexed or less rigid and more prone to bending

grout: a heavily filled paste material used to fill crevices and transitions between piping components

heat fusion joint: a joint made by heating the surfaces to be joined and pressing them together so they fuse and become essentially one piece

hot gas welded joint: a joint made by simultaneously heating a filler material and the surfaces to be joined with a stream of hot air or hot inert gas until the materials soften, after which the surfaces to be joined are pressed together and welded with the molten filler material

liner: a coating or layer of material constructed as, applied to, or inserted within the inside surface of a piping component intended to protect the structure from chemical attack, to inhibit erosion, or to prevent leakage under strain

seal weld: the addition of material external to a joint by welding or bonding for the purpose of enhancing leak tightness

solvent cement joint: a joint using a solvent cement to soften the surfaces to be joined, after which the joining surfaces are pressed together and become essentially one piece as the solvent evaporates

stiffness factor: the measurement of a pipe's ability to resist deflection as determined in accordance with ASTM D 2412

thixatropic agent: a material added to resin to impart high static shear strength (viscosity) and low dynamic shear strength

ultraviolet absorber: a material which when combined in a resin mixture will selectively absorb ultraviolet radiation

woven roving: a heavy glass fiber fabric reinforcing material made by the weaving of glass fiber roving

III-1.3.2 Abbreviations used in this Appendix denote materials and terms as follows:

Abbreviation	Term
ABS[2]	Acrylonitrile-butadiene-styrene
AP	Polyacetal
CP	Chlorinated polyether
CPVC[2]	Chlorinated poly (vinyl chloride)
DS	Design stress
FEP[2]	Perfluoro (ethylene propylene)
HDB	Hydrostatic design basis
HDS	Hydrostatic design stress
PA[2]	Polyamide (nylon)
PB	Polybutylene
PE[2]	Polyethylene
PFA	Poly (perfluoroalkoxy)
POP	Poly (phenylene oxide)
PP[2]	Polypropylene
PPS	Polyphenylene
PR	Pressure rated
PTFE[2]	Polytetrafluoroethylene
PVC[2]	Poly (vinyl chloride)
PVDC	Poly (vinylidene chloride)
PVDF	Poly(vinylidene fluoride)
RTR	Reinforced thermosetting resin
SDR	Standard dimensional ratio

[2] Abbreviations in accordance with ASTM D 1600.

III-2.0 DESIGN

III-2.1 Conditions and Criteria

III-2.1.1 General

(A) The Design Conditions of para. 101 shall apply for the design of nonmetallic piping systems.

(B) The design of nonmetallic piping systems must ensure the adequacy of material and its manufacture, considering at least the following:

(B.1) tensile, compressive, flexural, shear strength, and modulus of elasticity at design temperature (long-term and short-term);

(B.2) creep characteristics for the service conditions;

(B.3) design stress and its basis;

(B.4) coefficient of thermal expansion;

(B.5) ductility and plasticity;

(B.6) impact and thermal shock properties;

(B.7) temperature limits for the service;

(B.8) transition temperatures: melting and vaporization;

(B.9) toxicity of the material or of the gases produced by its combustion or exposure to elevated temperatures;

(B.10) porosity and permeability;

(B.11) test methods;

(B.12) methods of making joints and their efficiency;

(B.13) deterioration in the service environment;

(B.14) the effects on unprotected piping from external heat sources (particularly solar radiation).

III-2.1.2 Pressure-Temperature Ratings for Components

(A) Components having specific pressure-temperature ratings have been established in the standards listed in Table III-4.1.1. Other components may be used in accordance with para. III-2.1.2(B).

(A.1) Except as qualified in paras. III-2.1.3, the ratings of Tables III-4.2.1, III-4.2.2, and III-4.2.3 are the limiting values for allowable stresses at temperature in this Appendix.

(A.2) The application of pressures exceeding the pressure-temperature ratings of valves is not permitted. Valves shall be selected for operation within the limits defined in para III-2.1.2(C)

(B) Components Not Having Specific Ratings

(B.1) Pipe and other piping components for which allowable stresses have been developed in accordance with para. III-2.1.3, but which do not have specific pressure-temperature ratings, shall be rated by the rules for pressure design in para. III-2.2 within the range of temperatures for which stresses are listed in Tables III-4.2.1, III-4.2.2, and III-4.2.3.

(B.2) Custom-molded pipe and other piping components that do not have allowable stresses or pressure-temperature ratings shall be qualified for pressure design as required in para. III-2.2.9.

(C) Allowances for Pressure and Temperature Variations. Allowances for variations of pressure, or temperature, or both, above design conditions are not permitted. The most severe conditions of coincident pressure and temperature shall be used to determine the design conditions.

(D) Considerations for Local Conditions. Where two services that operate at different pressure-temperature conditions are connected, the valve segregating the two services shall be rated for the most severe service conditions. Other requirements of para. 102.2.5 must be considered where applicable.

III-2.1.3 Allowable Stresses and Other Stress Limits

(A) General. Tables III-4.2.1, III-4.2.2, and III-4.2.3 list recommended maximum allowable stresses in the form of hydrostatic design stresses (HDS), allowable design stresses (DS), and the hydrostatic design basis (HDB), which may be used in design calculations except where modified by other provisions of this Appendix. The use of hydrostatic design stresses for calculations other than pressure design has not been established. The basis for determining allowable stresses and pressures is outlined in para. III-2.1.3(B). The allowable stresses are grouped by materials and listed for stated temperatures. Where sufficient data have been provided, straight-line interpolation between temperatures is permissible. The materials listed are available from one or more manufacturers and may be obtained with maximum allowable stresses varying from those listed in Tables III-4.2.1, III-4.2.2, and III-4.2.3. These materials and values are acceptable for use where they have been established in accordance with (B) below and para. III-2.2.9.

(B) Basis for Allowable Stresses for Internal Pressure

(B.1) Thermoplastics. A method of determining hydrostatic design stress (HDS) and pressure rating (PR) is described in ASTM D 2837. Hydrostatic design stresses are provided in Table III-4.2.1 for those materials and temperatures for which sufficient data have been compiled to substantiate a determination of stress. Data on these materials at other temperatures, and on other materials, are being developed. Pending publication of additional data, the limitations in para. III-2.1.2(B) shall be observed.

(B.2) Reinforced Thermosetting Resin (Laminated). For laminated piping components, the design stresses

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:52 2005

(DS) are listed in Table III-4.2.2. These typically are based on one-tenth of the minimum tensile strengths specified in Table 1 of ASTM C 582.

(B.3) Reinforced Thermosetting Resin (Filament Wound and Centrifugally Cast). For filament wound and centrifugally cast piping components, hydrostatic design basis (HDB) values are listed in Table III-4.2.3. These values may be obtained by procedures in ASTM D 2992. HDS may be obtained by multiplying the HDB by a service (design) factor[3] selected for the application, in accordance with procedures described in ASTM D 2992, within the following limits.

(B.3.1) When using the cyclic HDB from Table III-4.2.3, the service (design) factor shall not exceed 1.0.

(B.3.2) When using the static HDB from Table III-4.2.3, the service (design) factor shall not exceed 0.5.

III-2.1.4 Limits of Calculated Stresses due to Sustained Loads

(A) Internal Pressure Stresses. The limits for stress due to internal pressure are provided in para. III-2.2.2.

(B) External Pressure Stresses. Stresses due to uniform external pressures shall be considered safe when the wall thickness of the component, and means of stiffening, have been established in accordance with para. III-2.2.9.

(C) External Loading Stresses. Design of reinforced thermosetting resin (RTR) and thermoplastic piping under external loading shall be based on the results of the parallel plate loading test in ASTM D 2412. The allowable deflection for RTR and thermoplastic pipe shall be 5% of the pipe diameter. Where other nonmetallic piping is intended for use under conditions of external loading, it shall be subject to a crushing or three-edge bearing test, in accordance with ASTM C 14 or C 301, and the allowable load shall be 25% of the minimum value obtained.

III-2.1.5 Limits of Calculated Stresses due to Occasional Loads

(A) Operation. The total stress produced by pressure, live and dead loads, and by occasional loads, such as wind or earthquake, shall not exceed the considerations and recommendations in para. III-2.5. Wind and earthquake forces need not be considered as acting concurrently.

(B) Test. Stresses due to test conditions are not subject to the limitations in (A) above. It is not necessary to consider other occasional loads, such as wind and earthquake, as occurring concurrently with test loads.

III-2.1.6 Allowances

(A) Erosion, Corrosion, Threading, and Grooving. In determining the minimum required thickness of a piping component, allowances shall be included for erosion and for thread depth or groove depth.

(B) Mechanical Strength. When necessary, pipe wall thicknesses shall be increased to prevent overstress, damage, collapse, or buckling due to superimposed loads from supports, ice formation, backfill, or other causes. Where increasing thickness will cause excessive local stress, or is otherwise impractical, the required strength may be obtained through the use of additional supports, braces, or other means without an increased wall thickness. Particular consideration should be given to the mechanical strength of a small branch connected to large piping or to equipment.

III-2.2 Pressure Design of Piping Components

III-2.2.1 Criteria for Pressure Design. The design of piping components shall consider the effects of pressure and temperature in accordance with para. III-2.1.2, and provide for allowances in accordance with para. III-2.1.6. In addition, the design shall be checked for adequacy of mechanical strength under other applicable loadings as required in paras. III-2.1.4 and III-2.1.5.

(A) The required minimum wall thickness of straight sections of pipe t_m shall be determined in accordance with Eq. (1).

$$t_m = t + c \quad (1)$$

where

t_m = minimum required thickness, in.

t = pressure design thickness, in., as calculated in para. III-2.2.2 for internal pressure, or in accordance with para. III-2.2.3 for external pressure

c = the sum of the mechanical allowances (thread or groove depth), plus erosion and/or corrosion allowance, and the manufacturer's minus tolerance for product wall thickness, in. For threaded components, the nominal thread depth shall apply. For machined surfaces or grooves where a tolerance is not specified, the tolerance shall be assumed to be 0.02 in., in addition to the specified depth of the thread or groove.

[3] The service (design) factor should be selected by the designer after evaluating fully the service conditions and the engineering properties of the specific material under consideration. Aside from the limits in paras. III-2.1.3.(B.3.1) and (B.3.2), it is not the intent of the Code to specify service (design) factors.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:52 2005

III-2.2.2 Straight Pipe Under Internal Pressure

(A) The internal pressure design thickness t shall not be less than that calculated by the following equations.

(A.1) Thermoplastic Pipe

$$t = \frac{D}{2S_a/P + 1} \quad (2)$$

(A.2) Reinforced Thermosetting Resin (Laminated)

$$t = \frac{D}{2S_b/P + 1} \quad (3)$$

(A.3) Reinforced Thermosetting Resin (Filament Wound and Centrifugally Cast)

$$t = \frac{D}{2S_cF/P + 1} \quad (4)$$

where

D = outside diameter of pipe, in.
F = service design factor in accordance with para. III-2.1.3(B.3)
P = internal design gage pressure, psi
S_a = hydrostatic design stress from Table III-4.2.1
S_b = design stress from Table III-4.2.2
S_c = hydrostatic design basis from Table III-4.2.3

(B) The internal pressure design thickness t in (A.1) and (A.2) above shall not include any thickness of pipe wall reinforced with less than 30% (by weight) of reinforcing fibers, or added liner thickness.

III-2.2.3 Straight Pipe Under External Pressure

(A) Thermoplastic Pipe. The external pressure design thickness t shall be qualified as required by para. III-2.2.9

(B) Reinforced Thermosetting Resin Pipe

(B.1) Above Ground. For determining design pressure thickness for straight pipe under external pressure, the procedures outlined in ASTM D 2924 shall be followed. A safety factor of at least 4 shall be used.

(B.2) Below Ground. For determining design pressure thickness for straight pipe under external pressure in a buried condition, the procedures outlined in AWWA C-950, Appendix A, Sections A-2.5 and A-2.6 shall be followed.

(C) Metallic Pipe Lined With Nonmetals

(C.1) The external pressure design thickness for the base (outer) material shall be determined in accordance with para. 104.1.3.

(C.2) The external pressure design thickness t for the lining material shall be qualified as required by para. III-2.2.9.

III-2.2.4 Curved and Mitered Segments of Pipe

(A) Pipe Bends. The minimum required thickness t_m of a pipe bend after bending shall be determined as for straight pipe in accordance with para. III-2.2.1.

(B) Elbows. Manufactured elbows not in accordance with para. III-2.1.2 shall meet the requirements of para. III-2.2.9.

(C) Mitered Bends. Mitered bend sections shall meet the requirements of para. III-2.2.9.

III-2.2.5 Branch Connections

(A) General. A pipe having a branch connection is weakened by the opening that must be made in it, and unless the wall thickness of the pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide added reinforcement. The amount of reinforcement required shall be in accordance with the requirements of para. III-2.2.9 except as provided in (B) and (C) below.

(B) Branch Connections Using Fittings. A branch connection shall be considered to have adequate strength to sustain the internal and external pressure which will be applied to it if a fitting (a tee, lateral, or cross) is utilized in accordance with para. III-2.1.2(A).

(C) Additional Considerations. The requirements of (A) and (B) above are designed to assure satisfactory performance of a branch connection subjected only to internal or external pressure. The designer shall also consider the following:

(C.1) external forces and moments which may be applied to a branch connection by thermal expansion and contraction, by dead and live loads, by vibration or pulsating pressure, or by movement of piping terminals, supports, and anchors;

(C.2) adequate flexibility shall be provided in branch piping to accommodate movements of the run piping;

(C.3) ribs, gussets, or clamps may be used for pressure-strengthening a branch connection in lieu of the reinforcement required by (A) above if the adequacy of the design is established in accordance with para. III-2.2.9.

III-2.2.6 Closures. Closures in piping systems, such as those provided for temporary or future lateral or end-point branches, shall be made using fittings, flanges, or parts in accordance with paras. III-2.2.7 and III-2.2.9.

III-2.2.7 Pressure Design of Flanges

(A) General

(A.1) Nonmetallic flanges that are rated in accordance with published ASTM standards listed in Table III-4.1.1 shall be considered suitable for use within the limitations specified in this Appendix. Alternatively,

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:52 2005

flanges shall be in accordance with para. 103, or may be designed in conformance with the requirements of para. III-2.2.7 or III-2.2.9.

(A.2) Flanges for use with ring type gaskets may be designed in accordance with Section VIII, Division 1, Appendix 2 of the ASME Boiler and Pressure Vessel Code, except that the allowable stresses for nonmetallic components shall govern. All nomenclature shall be as defined in the ASME Code except the following:

P = design gage pressure
S_a = bolt design stress at atmospheric temperature. (Bolt design stresses shall not exceed those in Appendix A.)
S_b = bolt design stress at design temperature. (Bolt design stresses shall not exceed those in Appendix A.)
S_f = allowable stress for flange material from Para. III-4.2

(A.3) The flange design rules in (A.2) above are not applicable for designs employing full-face gaskets that extend beyond the bolts or where flanges are in solid contact beyond the bolts. The forces and reactions in such a joint differ from those joints employing ring type gaskets, and the flanges should be designed in accordance with Section VIII, Division 1, Appendix Y of the ASME Boiler and Pressure Vessel Code. (Note that the plastic flange sealing surface may be more irregular than the sealing surface of a steel flange. For this reason, thicker and softer gaskets may be required for plastic flanges.)

(B) Blind Flanges. Blind flanges shall be in accordance with para. 103, or alternatively, may be designed in accordance with para. 104.5.2, except that the allowable stress for nonmetallic components shall be taken from the data in para. III-4.2. Otherwise, the design of blind flanges shall meet the requirements of para. III-2.2.9.

III-2.2.8 Reducers. Reducers not in compliance with para. 103 shall meet the requirements of para. III-2.2.9.

III-2.2.9 Design of Other Components

(A) Listed Components. Other pressure-retaining components manufactured in accordance with standards listed in Table III-4.1.1 may be utilized in accordance with para. III-2.1.2.

(B) Unlisted Components and Products. For pressure-retaining components and piping products not in accordance with the standards and specifications in Table III-4.1.1, and for proprietary components and joints for which the rules in paras. III-2.2.1 through III-2.2.8 do not apply, pressure design shall be based on calculations consistent with the design criteria of the Code. This must be substantiated by one or more of the following, with consideration given to applicable dynamic effects, such as vibration and cyclic operation, the effects of thermal expansion or contraction, and the load effects of impact and thermal shock:

(B.1) extensive successful service experience under comparable design conditions with similarly proportioned components or piping elements made of the same or like material;

(B.2) performance tests under design conditions, including applicable dynamic and creep effects, continued for a time period sufficient to determine the acceptability of the component or piping element for its design life;

(B.3) for either (B.1) or (B.2) above, reasonable interpolations between sizes and pressure classes and reasonable analogies among related materials are permitted.

III-2.3 Selection of Piping Components

III-2.3.1 General. Nonmetallic pipe, tubing, fittings, and miscellaneous items conforming to the standards and specifications listed in Table III-4.1.1 shall be used within the limitations of para. III-4.0 of this Appendix.

III-2.4 Selection of Piping Joints

III-2.4.1 General. Joints shall be suitable for the pressure-temperature design conditions and shall be selected giving consideration to joint tightness and mechanical strength under those conditions (including external loadings), the materials of construction, the nature of the fluid service, and the limitations of paras. III-2.4.2 through III-2.4.7.

III-2.4.2 Bonded Joints

(A) General Limitations. Unless limited elsewhere in para. III-2.4.2, joints made by bonding in accordance with para. III-5.1, and examined in accordance with para. III-6.2, may be used within other limitations on materials and piping components in this Appendix.

(B) Specific Limitations

(B.1) Fillet Joints. Fillet bonded joints may be used in hot gas welded joints, only, if in conformance with the requirements of para. III-5.1.3(A).

(B.2) Butt-and-Wrapped Joints. Butt-and-wrapped joints in RTR piping shall be made with sufficient strength to withstand pressure and external loadings.

III-2.4.3 Flanged Joints

(A) General Limitations. Unless limited elsewhere in

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:53 2005

para. III-2.4.3, flanged joints may be used, considering the requirements for materials in para. III-3.0, and for piping components in para. III-2.3, within the following limitations.

(A.1) Joints With Flanges of Different Ratings. Where flanges of different ratings are bolted together, the rating of the joint shall be that of the lower rated flange. Bolting torque shall be limited so that excessive loads will not be imposed on the lower rated flange in obtaining a tight joint.

(A.2) Metallic to Nonmetallic Flanged Joints. Where metallic and nonmetallic flanges are to be joined, both should be flat-faced. Full-faced gaskets are preferred. If full-faced gaskets are not used, bolting torque shall be limited so that the nonmetallic flange is not overloaded.

III-2.4.4 Expanded or Rolled Joints. Expanded or rolled joints are not permitted in nonmetallic piping systems.

III-2.4.5 Threaded Joints

(A) General Limitations

(A.1) Threaded joints may be used within the requirements for materials in para. III-3.0, and on piping components in para. III-2.3, within the following limitations.

(A.2) Threaded joints shall be avoided in any service where severe erosion or cyclic loading may occur, unless the joint has been specifically designed for these conditions.

(A.3) Where threaded joints are designed to be seal welded, thread sealing compound shall not be used.

(A.4) Layout of piping should minimize reaction loads on threaded joints, giving special consideration to stresses due to thermal expansion and the operation of valves.

(A.5) Metallic-to-nonmetallic and dissimilar nonmetallic threaded joints are not permitted in piping $2\frac{1}{2}$ in. NPS, and larger.

(A.6) Threaded joints are not permitted at design temperatures above 150°F.

(B) Specific Limitations

(B.1) Thermoplastic Resin Piping. Threaded joints in thermoplastic piping shall conform to the following requirements.

(B.1.1) The pipe wall shall be at least Schedule 80 thickness.

(B.1.2) Pipe threads shall conform to ASME B1.20.1 NPT. Threaded fittings shall be compatible with that standard.

(B.1.3) A suitable thread lubricant and sealant shall be specified.

(B.1.4) Threaded piping joints are not permitted in polyolefin materials[4] because of creep characteristics that must be considered.

(B.2) Thermosetting Resin Piping. Threaded joints in thermosetting resin piping shall conform to the following requirements.

(B.2.1) Threads shall be factory cut or molded on pipe ends and in matching fittings, with allowance for thread depth in accordance with para. III-2.2.1(A).

(B.2.2) Threading of plain ends of piping is not permitted except where such male threads are limited to the function of forming a mechanical lock with matching female threads during bonding.

(B.2.3) Factory cut or molded threaded nipples, couplings, or adapters bonded to plain end components, may be used where necessary to provide connections to threaded metallic piping.

III-2.4.6 Caulked Joints. In liquid service, bell and spigot and other caulked joints shall be used within the pressure-temperature limitations of the joints and the components. Provisions shall be made to prevent disengagement of the joints at bends and dead ends and to support lateral reactions produced by branch connections or other causes.

III-2.4.7 Proprietary Joints. Metal coupling, mechanical, gland and other proprietary joints may be used within the limitations on materials in para. III-3.0, on components in para. III-2.3, and the following.

(A) Adequate provisions shall be made to prevent the separation of joints under internal pressure, temperature and external loads.

(B) Prior to acceptance for use, a prototype joint shall be subjected to performance tests to determine the safety of the joint under test conditions simulating all expected fluid service conditions.

III-2.5 Expansion and Flexibility

III-2.5.1 General Concepts

(A) Elastic Behavior. The concept of piping strain imposed by the restraint of thermal expansion or contraction, and by external movements, applies in principle to nonmetals. Nevertheless, the assumption that stresses can be predicted from these strains in a nonmetallic piping system, based on the linear elastic characteristics of the material, is generally not valid. The variation in elastic characteristics between otherwise similar material types, between source manufacturers, and between batch

[4] The polyolefin group of materials includes polyethylene, polypropylene, and polybutylene.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:53 2005

lots of the same source material, can at times be significant. If a method of flexibility analysis that assumes elastic behavior is used, the designer must be able to demonstrate its validity for the system and must establish conservative limits for the computed stresses.

(B) Overstrained Behavior. Stresses cannot be considered proportional to displacement strains in nonmetallic piping systems where an excessive level of strain may be produced in a localized area of the system, and in which elastic behavior of the piping material is uncertain. (See unbalanced systems in para. 119.3 of the Code.) Overstrain must be minimized by effective system routing in order to avoid the necessity of a requirement for special joints or expansion devices for accommodating excessive displacements.

(C) Progressive Failure. In thermoplastics and some thermosetting resins, displacement strains are not likely to produce immediate failure of piping but may produce unacceptable distortion. Thermoplastics, particularly, are prone to progressive deformation that may occur upon repeated thermal cycling or under prolonged exposure to elevated temperature.

(D) Brittle Failure. In brittle thermosetting resins, the materials are essentially rigid in behavior and may readily develop high-displacement stresses, to the point of sudden breakage or fracture, under moderate levels of strain.

III-2.5.2 Properties for Flexibility Analysis

(A) Thermal Expansion Data. Table III-4.3.1 of this Appendix lists coefficients of thermal expansion for several nonmetallic materials. More precise values in some instances may be obtained from the manufacturers of these materials. If these values are to be used in stress analysis, the thermal displacements shall be determined as indicated in para. 119.

(B) Modulus of Elasticity. Table III-4.3.2 lists representative data on the tensile modulus of elasticity E for several nonmetals. More precise values in some instances may be obtained from the materials manufacturer. (Note that the modulus may vary with the geometrical orientation of a test sample for filler-reinforced, filament-wound, or impregnated nonmetallic materials.) For materials and temperatures not listed, refer to an authoritative source, such as publications of the National Bureau of Standards.

(C) Poisson's Ratio. For nonmetals, Poisson's ratio will vary widely, depending upon materials and temperature. For that reason formulas used in linear elastic stress analysis can be used only if the manufacturer has test data to substantiate the use of a specific Poisson's ratio for that application.

(D) Dimensions. The nominal thickness and outside diameters of pipe and fittings shall be used in flexibility calculations.

III-2.5.3 Analysis

(A) Formal stress analysis is not required for systems that:

(A.1) are duplicates, or replacements without significant change, of successfully operating installations; or

(A.2) can readily be judged adequate by comparison with previously analyzed systems; or

(A.3) are routed with a conservative margin of inherent flexibility, or employ joining methods or expansion joint devices, or a combination of these methods, in accordance with applicable manufacturer's instruction.

(B) A substantiating stress analysis is required for a system not meeting the above criteria. The designer may demonstrate that adequate flexibility exists by employing a simplified, approximate, or comprehensive stress analysis, using a method that can be shown to be valid for the specific case. If essentially elastic behavior can be demonstrated for a piping system [see para. III-2.5.1(A)], the methods outlined in para. 119 may be applicable.

(C) Special attention shall be given to movement (displacement or rotation) of the piping with respect to supports and points of close clearance. Movements of a run at the junction of a small branch shall be considered in determining the need for flexibility in the branch.

III-2.5.4 Flexibility

(A) Piping systems shall have sufficient flexibility to prevent the effects of thermal expansion or contraction, the movement of pipe supports or terminal points, or pressure elongation from causing:

(A.1) failure of piping or supports from overstrain or fatigue;

(A.2) leakage at joints; or

(A.3) unacceptable stresses or distortion in the piping or in connected equipment.

(B) Where nonmetallic piping and components are used, piping systems must be designed and routed so that flexural stresses resulting from displacements due to expansion, contraction and other causes are minimized. This concept requires special attention for supports and restraints, the terminal connections, and for the techniques outlined in para. 119.5.1. Further infor-

Copyright by the American Society Of Mechanical Engineers

mation on the design of thermoplastic piping can be found in PPI Technical Report TR-21.

III-2.6 Design of Pipe Supporting Elements

III-2.6.1 General. In addition to the other applicable requirements of paras. 120 and 121, supports, guides, and anchors shall be selected and applied to comply with the requirements of para. III-2.5, and the following.

(A) Support or restraint loads shall be transmitted to piping attachment or bearing points in a manner that will preclude pipe wall deformation or damage. Padding or other isolation material should be installed in support or restraint clearance spaces for added protection.

(B) Valves and in-line components shall be independently supported to prevent the imposition of high load effects on the piping or adjacent supports.

(C) Nonmetallic piping should be guarded where such systems are exposed to casual damage from traffic or other work activities.

(D) A manufacturer's recommendations for support shall be considered.

III-2.6.2 Thermoplastic and RTR Piping. Supports shall be spaced to avoid excessive displacement at design temperature and within the design life of the piping system. Decreases in the modulus of elasticity, with increasing temperature, and creep of the material, with time, shall be considered where applicable. The coefficient of thermal expansion of most plastic materials is high and must be considered in the design and location of supports and restraints.

III-2.7 Burial of RTR Pipe

III-2.7.1 Design. The design procedures of ANSI/AWWA C-950, Appendix A shall apply. A minimum pipe stiffness shall meet the requirements in Table 6 of ANSI/AWWA C-950. The minimum stiffness ($F/\Delta y$) shall be determined at 5% deflection using the apparatus and procedures of ASTM D 2412.

III-2.7.2 Installation. The pipe manufacturer's recommendations shall be equal to or more stringent than those described in ASTM D 3839 for RTR pipe or ASTM D 2774 for thermoplastic pipe. The manufacturer's recommendations should be followed.

III-3.0 MATERIALS

III-3.1 General Requirements

Paragraph III-3.0 provides limitations and qualifications for materials based on their inherent properties. The use of these materials in piping may also be subject to requirements and limitations in other parts of the Code.

III-3.2 Materials and Specifications

III-3.2.1 Listed Materials. Listed materials used in pressure containing piping shall have basic allowable stresses and other design limits as covered in para. III-2.1.

III-3.2.2 Unlisted Materials. Unlisted materials used in pressure containing piping shall have basic allowable stresses and other design limits determined in accordance with para. III-2.1, or on a more conservative basis.

III-3.2.3 Unknown Materials. Materials of an unknown specification or standard shall not be used.

III-3.2.4 Reclaimed Materials. Reclaimed piping components may be used provided they are properly identified as conforming to a listed specification and otherwise meet the requirements of this Appendix. Sufficient cleaning and examination shall be performed to determine that the components are acceptable for the intended service, considering at least the following:

(A.1) minimum available wall thickness;

(A.2) extent of any imperfections;

(A.3) possible loss of strength;

(A.4) chemical absorption.

III-3.3 Temperature Limitations

The designer shall determine that materials which meet other requirements of this Appendix are suitable for the fluid service throughout the operating temperature range of the systems in which the materials will be used.

III-3.3.1 Upper Temperature Limitations

(A) The maximum design temperature for a listed material shall not exceed maximum temperatures listed in Tables III-4.2.1, III-4.2.2, or III-4.2.3, as applicable, except as provided in para. III-2.1.3(A).

(B) An unlisted material acceptable under para. III-3.2.2 shall have upper temperature limits established in accordance with para. III-2.1.2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:54 2005

III-3.3.2 Lower Temperature Limitations

(A) The minimum design temperature for a listed material shall not be lower than the minimum temperatures listed in Tables III-4.2.1 and III-4.2.2, as applicable, except as provided in para. III-2.1.3(A).

(B) An unlisted material acceptable under para. III-3.2.2 shall have lower temperature limits established in accordance with the manufacturer's recommendation but in no case less than –20°F.

III-3.4 Fluid Service Limitations

III-3.4.1 General Limitations. The use of nonmetallic piping materials and components, under the scope of this Appendix, shall be limited to those services and conditions stated in para. III-1.2.2. In addition:

(A) nonmetallic materials shall not be used under severe cyclic conditions unless it can be demonstrated that the materials are suitable for the intended service in accordance with para. III-2.2.9;

(B) these materials shall be appropriately protected against transient or operating temperatures and pressures beyond design limits, and shall be adequately protected against mechanical damage;

(C) limitations on the use or application of materials in this Appendix apply to pressure containing parts. They do not apply to the use of materials for supports, linings, gaskets, or packing.

III-3.4.2 Specific Material Limitations

(A) Thermoplastics shall be installed and protected against elevated temperatures.

(B) Thermosetting and fiber-reinforced thermosetting resins shall be limited to the services stated in para. III-1.2.3 and shall be installed and protected against mechanical damage, vibration, and excessive cyclic strain in service.

III-3.4.3 Miscellaneous Materials: Joining and Auxiliary Materials. When selecting materials, such as cements, solvents, packing, and O-rings for making or sealing joints, the designer shall consider their suitability for the fluid service.

III-3.5 Piping Component Requirements

III-3.5.1 Dimensions of Piping Components

(A) Listed Piping Components. Dimensions of listed piping components, including tolerances, shall conform to the applicable piping component specification or standard listed in Table III-4.1.1.

(B) Unlisted Piping Components. Dimensions of unlisted piping components, including tolerances, shall conform to those of comparable listed piping components insofar as practical. In all cases, dimensions shall be such as to provide strength and performance equivalent to listed piping components and shall meet the requirements of para. III-2.2.9.

(C) Threads. Dimensions of piping connection threads not covered by a governing component specification or standard shall conform to para. III-2.4.5.

III-4.0 SPECIFICATIONS AND STANDARD DATA

III-4.1 Material Specifications and Standards

III-4.1.1 Standard Piping Components. Dimensions of standard piping components shall comply with the standards and specifications listed in Table III-4.1.1, in accordance with the requirements of para. III-2.1.2(A). Abbreviations used in this Appendix and in Table III-4.1.1 are listed in para. III-1.3.2.

III-4.1.2 Nonstandard Piping Components. Where nonstandard piping components are designed in accordance with para. III-2.2, adherence to dimensional standards of ANSI and ASME is strongly recommended where practical.

III-4.1.3 Reference Documents

(A) The documents listed in Table III-4.1.1 may contain references to codes, standards, or specifications not listed in the Table. Such unlisted codes, standards, or specifications are to be used only in the context of the listed documents in which they appear.

(B) Where documents listed in Table III-4.1.1 contain design rules that are in conflict with this Appendix, the design rules of this Appendix shall govern.

(C) The fabrication, assembly, examination, inspection, and testing requirements of Parts 5 and 6 of this Appendix apply to the construction of piping systems. These requirements are not applicable to the manufacture of material or components listed in Table III-4.1.1, unless specifically stated.

III-4.2 Stress and Temperature Limits

Tables III-4.2.1, III-4.2.2, and III-4.2.3 provide listings of the stress and recommended temperature limits for the following, in accordance with paras. III-2.1.3(A) and (B).

III-4.2.1 Thermoplastic Piping Components. Table III-4.2.1 provides hydrostatic design stresses (HDS) and recommended temperature limits for thermoplastic piping components.

Notes for this Table follow below Table III-4.2.3

any marking paint or ink shall not be detrimental to the piping material. In lieu of marking the bond, appropriate records shall be filed.

III-5.1.2 Qualification

(A) Qualification of the BPS to be used, and of the performance of bonders and bonding operators, is required. Bonding Procedure Specifications shall specify, for both the bonding operation and qualification testing requirements, all required materials, including material storage requirements; the fixtures and tools required, including the care of tools; and the temperature requirements for all operations, including the methods required for temperature measurement.

(B) Bonding Responsibility. An employer of bonding personnel is responsible for the bonding done by members of his organization and, except as provided in (C) below, shall conduct the required performance qualification tests to qualify the bonding procedure specifications and the bonders or bonding operators.

(C) Qualification by Others

(C.1) Bonding Procedure Specification (BPS). The piping system erector shall be responsible for qualifying a BPS that personnel of his organization will use. Subject to the specific approval of the designer, a BPS qualified by others may be used if the following conditions apply.

(C.1.1) The designer accepts that the proposed qualified BPS has been prepared and executed by a responsible recognized organization with expertise in the field of bonding.

(C.1.2) The designer accepts both the BPS and Procedure Qualification Record (PQR) by signature as his own.

(C.1.3) The piping erector has at least one bonder, currently employed, who has satisfactorily passed a performance qualification test using the proposed qualified BPS.

(C.2) Bonding Performance Qualification. A piping erector shall not accept a performance qualification test made by a bonder or bonding operator for another piping erector without the designer's specific approval. If approval is given, acceptance is limited to performance qualification tests on piping using the same or an equivalent BPS. The piping erector accepting such performance qualification tests shall obtain a copy of the PQR from the previous erector, showing the name of the piping erector by whom bonders or bonding operators were qualified, the dates of such qualification, and the date the bonder or bonding operator last assembled pressure piping under the previous performance qualification.

(D) Qualification tests for the bonding procedure and operator performance shall comply with the requirements of the BPS and the following.

(D.1) A test assembly shall be fabricated in accordance with the bonding procedure specification. The test assembly shall consist of at least one pipe-to-pipe joint and one pipe-to-fitting joint. The size of the pipe used for the test assembly shall be as follows.

NOTES TO TABLES III-4.2.1, III-4.2.2, AND III-4.2.3:
(1) These recommended limits are for low pressure applications with water and other fluids that do not significantly affect the properties of the thermoplastic material. In conservative practice, the upper temperature limits may be reduced at higher pressures depending on the required service and expected life. Lower temperature limits are affected more by the environment, safeguarding, and installation conditions than by strength.
(2) Because of low thermal conductivity, temperature gradients through the piping component wall may be substantial. Tabulated limits apply where more than half the wall thickness is at or below the stated temperature.
(3) These recommended limits apply only to listed materials. Manufacturers should be consulted for temperature limits on specific types and kinds of materials not listed.
(4) Minimum for installation.
(5) Maximum for operation.
(6) Use these hydrostatic design stress values at all lower temperatures.
(7) The design stress (DS) values apply only in the temperature range of −20°F through 180°F.
(8) A service (design) factor must be applied to these HDB values to obtain the HDS.
(9) These HDB values apply only at 73°F.
(10) Recommended temperature limits for these materials are shown in Table III-4.2.2.
(11) When using the cyclic design basis, the service factor shall not exceed 1.0.
(12) When using the static design basis, the service factor shall not exceed 0.5.

(D.1.1) When the largest size to be joined (within the BPS) is 4 in. NPS or smaller, the test assembly shall be the same NPS as the largest size to be joined.

(D.1.2) When the largest size to be joined within the BPS is greater than 4 in. NPS, the test assembly shall be made of piping components either 4 in. NPS or a minimum of 25% of the NPS of the largest piping component to be joined, whichever is larger.

(D.2) The test assembly shall be subjected to one of the following qualification test operations.

(D.2.1) When the test assembly has been cured, it shall be subjected to a hydrostatic pressure test of the

NOTE:
(1) The modulus of elasticity values for thermosetting resin pipe are given in the longitudinal direction; different values may apply in the circumferential or hoop direction. The modulus of elasticity values for thermoplastic resin pipe are temperature-dependent and stress-time related. Values noted with an asterisk (*) have not been confirmed by industry-accepted standards. In all cases for materials listed in this Table, manufacturers may be consulted for specific product information.

maximum of either 150 psig or 1.5 times an equivalent allowable pressure which shall be calculated using the least nominal wall thickness and outside diameter of the pipe in the test assembly. This pressure shall be determined using the equation in para. III-2.2.2(A) for the test material. The test shall be conducted so that the joint is loaded in both the circumferential and longitudinal directions. Joints shall not leak or separate when tested.

(D.2.2) When a test assembly is joined by heat fusion, the fusion joints may be tested by cutting a minimum of three coupons containing the joint and bending the strips using a procedure which shall be defined in the BPS. As a minimum requirement, the test strips shall not break when bent a minimum of 90 deg, at ambient temperature, over an inside bend radius of 1.5 times the nominal diameter of the tested pipe.

(E) Performance Requalification

(E.1) Renewal of a bonding performance qualification is required when:

(E.1.1) a bonder or bonding operator has not used

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:57 2005

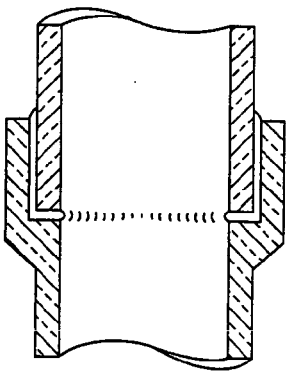

FIG. III-5.1.3(A)

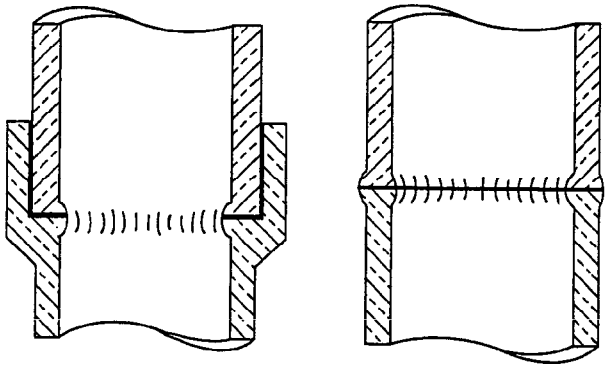

FIG. III-5.1.3(B)

the specific bonding process for a period of time greater than 6 months, or a specific maximum period of time otherwise permitted in the BPS for the work;

(E.1.2) there is a specific reason to question a bonder or bonding operator's ability to make bonds that meet the BPS.

(E.2) Renewal of a bonding performance qualification for a specific bonding process may be made in only a single test assembly.

(F) Qualification Records. An erector using bonders, or bonder operators, shall maintain a record of the procedures used and of operators employed by him who are qualified in these procedures.

III-5.1.3 Thermoplastic Joints

(A) Solvent-Cemented Joints

(A.1) Preparation. PVC and CPVC surfaces to be cemented shall be cleaned by wiping with a clean cloth moistened with acetone or methylethyl ketone. Cleaning for ABS shall conform to ASTM D 2235. Cuts shall be free of burrs and circumferential cuts shall be as square as those obtained by the use of a saw with a miter box or a square-end sawing vise. A slight interference fit between the pipe and a fitting socket is preferred, and the diametral clearance between a pipe and the entrance of a mating socket shall not exceed 0.04 in. This fit shall be checked before solvent cementing.

(A.2) Procedure. Joints shall be made in accordance with a qualified BPS. ASTM D 2855 provides a suitable basis for such a procedure. Solvent cements for PVC, CPVC, and ABS shall conform to ASTM D 2564, D 2846, and D 2235, respectively. Cement shall be applied to both joint surfaces. The amount of cement shall be sufficient to produce a small continuous fillet of cement at the outer limits of the joints. See Fig. III-5.1.3(A)

(A.3) Branch Connections. For branch connections not using a tee, a manufactured full reinforcement saddle with an integral branch socket shall be solvent cemented to the run pipe over its entire contact surface.

(A.4) Limitations on Imperfections. Imperfections exceeding the following limitations are considered defects and shall be repaired and reexamined in accordance with para. III-5.1.5:

(A.4.A) protrusion of dried cement exceeding 50% of pipe wall thickness into the bore of the pipe; or

(A.4.B) unfilled or unbonded areas in a joint as indicated by the lack or interruption of the continuous fillet noted in (A.2) above.

(B) Heat Fusion Joints

(B.1) Preparation. Surfaces to be heat fused together shall be cleaned of any foreign material. Cuts shall be free of burrs, and circumferential cuts shall be as square as those obtained by the use of a saw with a miter box or a square-end sawing vise.

(B.2) Procedure. Joints shall be made in accordance with a qualified BPS. The general procedures in ASTM D 2657, Technique I-Socket Fusion, II-Butt Fusion, and III-Saddle Fusion provide a suitable basis for such a procedure. Both surfaces to be joined shall be uniformly heated to produce a continuous homogeneous bond between them. This will produce a small continuous fillet of fused material at the outer limits of the joints. See Fig. III-5.1.3(B).

(B.3) Branch Connections. Branch connections shall be made only with the use of molded fittings in sizes that are commercially available.

(B.4) Limitations on Imperfections. Imperfections exceeding the following limitations are considered defects and shall be repaired and reexamined in accordance with para. III-5.1.5:

(B.4.A) protrusion of fused material exceeding 25% of the pipe wall thickness into the bore of the pipe; or

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:58 2005

01 *(B.4.B)* unfilled or unbonded areas in a joint as indicated by the lack or interruption of the continuous fillet noted in (B.2) above.

III-5.1.4 Thermosetting Resin Joints

(A) Preparation. Cutting of pipe and preparation of bonding surfaces shall be done, as recommended by the manufacturer, without chipping or cracking of the cut ends; particularly, the inner surface of centrifugally cast pipe. Pipe may be preheated, if necessary, to comply with the above requirements. Cuts shall be free of burrs, and circumferential cuts shall be as square as required by the purchaser's specifications or the recommendations of the manufacturer, whichever requires the closer squareness. For branch connections, holes in the run pipe may be made with a hole saw. Mold release agent and any other material which may interfere with adhesion shall be removed from surfaces to be bonded.

(B) Joining Procedures

(B.1) Socket and Spigot Joints. Joints shall be made in accordance with a qualified BPS based on the manufacturer's recommended procedure. Application of adhesive to the surfaces to be joined, and assembly of those surfaces shall produce a continuous bond between them. Cut ends of the pipe and edges of the laminate fabric shall be sealed to prevent fluid penetration of the pipe wall or the laminate material.

(B.2) Butt-and-Wrap Joints. Joints shall be made in accordance with a qualified BPS. The general procedures in ASTM C 582 Contact-Molded Reinforced Thermosetting Plastic (RTP) Laminates for Corrosion Resistant Equipment provide a suitable basis for the development of such a procedure. Application of plies of reinforcement, saturated with catalyzed resin, to the surfaces to be joined shall produce a continuous structure with the surfaces. Cut ends shall be sealed as required in (B.1) above.

(C) Branch Connections. Branch connections shall be made using a manufactured tee fitting or a full reinforcement saddle having suitable provisions for joining as in (B) above. The cut edges of any hole in the run pipe shall be sealed with adhesive at the time the saddle is bonded to the run pipe.

(D) Limitations on Imperfections. Imperfections exceeding the following limitations are considered defects and shall be repaired and reexamined in accordance with para. III-5.1.5:

(D.1) protrusion of adhesive exceeding 25% of pipe wall thickness into the bore at the bottom of a socket, or inside a branch connection; or

(D.2) unfilled or unbonded areas in the joint.

III-5.1.5 Repair of Defects. Defective material, joints and other workmanship in piping which fail to meet the requirements of paras. III-3.0 and III-5.0, and of the engineering design, shall be repaired or replaced. Limitations on imperfections, and the method and extent of the required examination of repairs and replacements, shall be the same as for the original work.

III-5.2 Bending

III-5.2.1 Pipe Bending. Flattening of a bend is defined as the difference between the maximum and minimum outside diameters, at any cross section, expressed as a percentage of the nominal outside diameter. Flattening shall not exceed 8% for pipe exposed to internal pressure. For pipe under external pressure, flattening shall not exceed 3%. The thickness after bending shall not be less than that required in para. III-2.2.4(A).

III-5.2.2 Bending Methods. Pipe may be bent by any suitable hot or cold method permissible by radii limitations and material characteristics of the pipe being bent. Hot bending shall be done within a temperature range consistent with material characteristics, end-use requirements, and the pipe manufacturer's recommendations.

III-5.3 Component Forming

Piping components may be formed by any suitable hot or cold method permissible by the characteristics of the material being formed. Forming shall be done within a temperature range consistent with the material characteristics, end-use requirements, and the component manufacturer's recommendations. The thickness after forming shall not be less than that required by the engineering design.

III-5.4 Assembly and Erection

III-5.4.1 General. The assembly and erection of nonmetallic piping systems shall comply with the requirements of para. 135 of the Code and para. III-5.0 of this Appendix. In addition:

(A) when assembling nonmetallic flanges, flat washers shall be used under all bolt heads and nuts. The specified maximum bolt torque shall not be exceeded.

(B) full circumference wrenches shall be used to tighten threaded pipe joints. Tools and other devices used to hold or apply forces to the pipe shall be such that pipe surfaces are not scored or deeply scratched. For thermosetting resin piping, threads shall be coated

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:58 2005

with sufficient adhesive to cover the threads and completely fill the clearance between the pipe and fittings.

III-6.0 EXAMINATION, INSPECTION, AND TESTING

III-6.1 General

The general requirements of Chapter VI with regard to visual examination and leak testing are basically applicable to nonmetallic piping systems.

III-6.2 Examination and Inspection

III-6.2.1 Visual Examination

(A) Visual examination is observation of the portion of components, joints, and other piping elements that are or can be exposed to view before, during, or after manufacture, fabrication, assembly, erection, inspection, or testing.

(B) Visual examination shall be performed in accordance with Article 9, Section V of the ASME Boiler and Pressure Vessel Code.

III-6.2.2 Examination Required

(A) Piping shall be examined at least to the extent required herein, or to any greater extent specified in the engineering design.

(A.1) Visually examine at least 5% of fabrication. For bonds (joints) each bonder or bonding operator's work shall be represented and shall include each type of bond for each bonder or bonding operator.

(A.2) Visually examine 100% of fabrication for bonds, other than circumferential bonds, and other than those in components made to material specifications recognized in this Code.

(A.3) Perform a random visual examination of the assembly of threaded, bolted, and other joints to satisfy the inspector that these conform to the requirements of para. III-5.4.1

(A.4) Perform a random visual examination during erection of piping, including checking of alignment and supports.

(A.5) Examine erected piping for evidence of damage that would require repair or replacement and for other deviations from the design.

(B) The inspector shall be assured, by examination of certifications, records, or other evidence that the materials and components are of the specified grades and that they have received the required examination and testing.

III-6.2.3 Extent of Required Examination. When visual examination reveals a defect requiring repair:

(A) two additional examinations of the same type shall be made of the same kind of item (if of a bond, others by the same bonder or bonding operator); and

(B) if the additional items examined as required by (A) above are acceptable, the item requiring repair shall be replaced or repaired and reexamined to meet the requirements of the Code, and all items represented by this additional examination shall be accepted; or

(C) if either of the items examined as required by (A) above reveals a defect, two additional items shall be examined; and

(D) if the additional items examined as required by (C) above are acceptable, the items requiring repair shall be replaced or repaired and reexamined to meet the requirements of the Code, and all items represented by this additional examination shall be accepted; or

(E) if either of the additional items examined as required by (C) above reveals a defect, all comparable items shall be replaced or they shall be fully examined, and all items requiring repair shall be repaired and reexamined to meet the requirements of the Code.

III-6.3 Pressure Tests

Leak tests, when specified shall be performed in accordance with para. 137.

NONMANDATORY APPENDIX IV[1]
CORROSION CONTROL FOR ASME B31.1 POWER PIPING SYSTEMS

FOREWORD

Present Code rules apply to the design, materials, fabrication, erection, tests, and inspection of new piping systems normally termed "new construction."

This nonmandatory Appendix contains guidelines that are applicable to existing operating piping systems contained in the scope of ASME B31.1, as well as "new construction."

Minimum requirements for corrosion control of power piping systems are outlined herein. It is recognized that many sound, although perhaps diverse, corrosion control programs exist. The philosophy used has been to establish minimum requirements. Users are encouraged to augment these guidelines to suit their particular needs and to offer constructive criticism to the Committee on this Appendix.

IV-1.0 GENERAL

IV-1.1

External and internal corrosion should be prevented or controlled consistent with design requirements and the environment in which the system is located.

IV-1.2

Application of corrosion control requires a significant amount of competent judgment. NACE[2] RP-01-69, Recommended Practice-Control of External Corrosion on Underground or Submerged Metallic Piping Systems, and RP-01-75, Recommended Practice-Control of Internal Corrosion in Steam Pipelines and Piping Systems, provide a guide for establishing the minimum requirements for control of corrosion of underground or submerged metallic piping systems. In addition, ASME B31G, Manual for Determining the Remaining Strength of Corroded Pipelines [3] may provide additional guidance.

IV-1.3

The following minimum requirements and procedures should be provided for protection of all piping systems containing hazardous liquids or gases and other piping as specified by the owner against internal, external, and atmospheric corrosion.

IV-2.0 EXTERNAL CORROSION CONTROL FOR BURIED OR SUBMERGED PIPELINES

IV-2.1 General

IV-2.1.1 Means to prevent or mitigate external corrosion of buried or submerged piping systems should be considered in the initial design, unless it can be demonstrated by tests, investigations, or experience in the area of installation that a detrimental corrosive environment does not exist.

IV-2.1.2 A means for control of external corrosion of buried or submerged pipe and components may be accomplished through application of an effective protective coating or wrapping. This method of corrosion control can be supplemented with cathodic protection such as sacrificial anodes, rectifier-ground bed units, and suitable drainage bonds in stray current areas. Materials should be selected with due regard to the type of supplemental corrosion protection employed.

IV-2.2 Protective Coating

IV-2.2.1 Protective coatings applied for the purpose of external corrosion should:

(A) be applied on a properly prepared surface;

(B) mitigate corrosion;

(C) have sufficient adhesion to the metal surface and be free of voids so as to effectively resist underfilm migration of moisture;

(D) be sufficiently ductile to resist cracking;

(E) have sufficient strength to resist damage due to handling and soil stress;

[1] Nonmandatory Appendices are identified by a Roman numeral; mandatory Appendices are identified by a letter. Therefore, Roman numeral I is not used in order to avoid confusion with the letter I.

[2] NACE: National Association of Corrosion Engineers, P.O. Box 1499, Houston, Texas 77001

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:59 2005

(F) be impact resistant.

IV-2.2.2 Coatings should have low moisture absorption characteristics and provide high electrical resistance. Properly compounded concrete coatings may be used.

IV-2.2.3 Pipe coatings should be inspected visually with a holiday detector and thickness gage prior to backfilling the excavation. Any bare spots, thin areas, holidays, or other damage to the coating should be repaired and reexamined prior to backfilling.

IV-2.2.4 Precautions should be taken to minimize pipe coating damage during installation if coated pipe is installed by boring, driving, or similar method.

IV-2.2.5 Pipe coatings should be protected from damage resulting from adverse ditch conditions or damage from supporting blocks. Only fine grain backfill is permitted in contact with the coating. This fine grain layer should be continuous and of sufficient thickness to prevent coating damage from larger articles in the backfill.

IV-2.2.6 The backfilling operation should be carefully controlled to prevent damage to pipe coatings.

IV-2.3 Cathodic Protection System

IV-2.3.1 Unless it can be demonstrated by investigation, tests, or experience that cathodic protection is not needed, a cathodic protection system should be installed for all new buried carbon steel, alloy, ductile iron, cast iron, aluminum or other metallic piping.

IV-2.3.2 All cathodic protection systems should comply with one or more of the criteria contained in Section 6 of the latest issue of the NACE Standard RP-01-69.

IV-2.3.3 Cathodic protection current should be controlled so as to prevent damage to the protective coating, pipe, or components.

IV-2.4 Electrical Isolation

IV-2.4.1 Buried or submerged coated and uncoated piping systems should be electrically isolated at all interconnections with neighboring systems except where arrangements are made for mutual cathodic protection or where underground metallic structures are electrically interconnected and cathodically protected as a unit. Electrical isolation of dissimilar metals, i.e., steel pipe connected to aluminum tanks, should be provided.

IV-2.4.2 Grounding of all piping systems, where required, should be in accordance with IEEE[3] Standard 142 or acceptable alternate standards.

IV-2.4.3 The electrical continuity of all buried or submerged metallic piping systems is recommended for proper station grounding, and to facilitate the installation of cathodic protection. Continuity across all mechanical joints should be achieved by electrical bonding.

IV-2.4.4 Where piping systems are located in near electrical transmission tower footings, ground cables, ground rods, or in other areas where fault currents or unusual risk of lightning may be anticipated, piping should be provided with protection against damage which may result from fault currents or lightning. Protective measures should also be taken at insulating devices where used.

IV-2.4.5 If a pipe culvert or sleeve is used, the encased pipe should be independently supported outside each end of the sleeve and electrically insulated throughout the length of the section.

IV-2.5 Electrical Interference

IV-2.5.1 The possibility of external corrosion induced by stray electrical currents in the earth is recognized. These stray currents are generated by sources independent of the piping system, and are more predominant in highly industrialized areas, mining regions, and locales containing high voltage, direct current, electrical power ground beds. Neighbor company pipeline cathodic protection systems are also a common source of stray earth currents.

IV-2.5.2 The protection of the piping system against stray current induced corrosion should be provided by metallic bonds, increased electrical cathodic protection, supplemental protective coatings, or insulating flanges.

IV-2.5.3 Each cathodic protection system provided for the plant piping should be designed and installed so as to minimize any adverse effects on adjacent underground metallic structures.

IV-3.0 INTERNAL CORROSION CONTROL

IV-3.1

Internal corrosion might occur during operation. A liquid or gas which will corrode the internal surfaces of piping should not be transported unless its corrosive

[3] IEEE: Institute of Electrical and Electronics Engineers, 445 Hose Lane, P.O. Box 1331, Piscataway, NJ 08855

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:55:59 2005

effects have been investigated. The piping material and any lining should be selected to be compatible with the flowing fluid to minimize corrosion, in accordance with NACE Standard RP-01-75.

IV-3.2 Inhibitors

If inhibitors are used to control internal corrosion, sufficient coupon samples or other types of monitoring techniques should be utilized to determine adequately the effectiveness of the inhibitors.

IV-3.3 Linings

If linings are used to prevent corrosion, they should meet the quality specifications established by the design engineer. They should be inspected in accordance with industry recommended practices. All base material and weld metal surfaces should be covered with the lining to at least the thickness specified by the designer.

IV-3.4 Precautions at Hydrotesting

Equipment fabricated from austenitic (300 series) and ferritic (400 series) stainless steels and requiring hydrostatic testing should be tested with deionized water, high purity steam condensate, or potable water, in decreasing order of preference.

NOTE: Potable water in this context follows U.S. practice, with 250 parts per million maximum chloride content, sanitized with chlorine or ozone.

After testing is completed, equipment should be thoroughly drained with all high point vents open during draining, and dried by air blowing, swabbing, or other appropriate means. If immediate draining and drying are not possible, hydrotest water should be circulated in the piping for at least one hour daily to reduce the possibility of pitting and microbiologically influenced corrosion.

IV-4.0 EXTERNAL CORROSION CONTROL FOR PIPING EXPOSED TO THE ATMOSPHERE

IV-4.1

Piping which is exposed to the atmosphere should be protected against external corrosion by use of corrosion resistant materials or by application of protective coatings or paints.

IV-5.0 MONITORING OF PIPE WALL THINNING DUE TO EROSION/ CORROSION

IV-5.1 Definition

Erosion/corrosion (E/C) is a flow accelerated corrosion process which leads to loss of wall thickness in carbon or low alloy steel pipe exposed to water or wet steam. The parameters that affect the rate of metal loss include water or steam temperature, pH, oxygen content of the fluid, steam quality, flow velocity and piping layout, and the piping chromium, copper, and molybdenum content. This para., IV-5.0, does not apply to other wall thinning mechanisms, such as general corrosion, microbiologically influenced corrosion, or cavitation.

IV-5.2 Systems and Components Susceptible to Erosion/Corrosion

Erosion/corrosion has caused piping failures or severe wall thinning in the following systems:

Feedwater, auxiliary feedwater
Feedwater recirculation
Condensate recirculation
Blowdown
Turbine crossaround/crossover
Extraction steam
Moisture separator reheater
Feedwater heater drains, drips, and vents

Piping damage due to E/C is not limited to these systems and may occur in any system of carbon steel or low alloy piping that is exposed to water or wet steam and operates at a temperature greater than 200°F. System parameters and their effect on E/C rates are shown in Table IV-5.2.

Typical piping components known to experience wall thinning due to E/C include elbows, tees, reducers, and closely coupled fittings. Piping downstream and upstream of these fittings and downstream of orifices and control valves is also susceptible.

IV-5.3 Methods of Detection

Detection of wall thinning due to E/C may be accomplished by a number of NDE techniques including visual, radiographic, ultrasonic, and other measurement methods. However, the most widely used method for detection of wall thinning caused by E/C is ultrasonic thickness examination. Current industry practice sup-

Wed Feb 02 00:56:00 2005

TABLE IV-5.2

Parameter	E/C Rate Increases if Parameter Is
Fluid velocity	Higher (> 10 fps for water) (> 150 fps for steam)
Fluid pH level	Less than 9.2
Fluid oxygen content	Less than 30 ppb
Fluid temperature	200°F–450°F (water) 200°F–500°F (wet steam)
Steam quality	Less than 100 %
Component geometry	Such as to create more turbulence
Component alloy content of chromium, copper, and molybdenum	Lower

ports use of a repeatable grid pattern with identifiable reference points at grid intersections. Grid sizes should not be greater than $2\sqrt{rt_n}$, where r is the outside radius and t_n is the nominal wall thickness of the piping item, except that grid sizes need not be smaller than 1 in. and should not be larger than 6 in. Thickness readings should be recorded at the grid intersection points and the pipe between the grid points scanned for detection of local thinning. If unacceptable thinning is detected, additional readings should be made and recorded with a refined or expanded grid. If thinning is detected within the boundaries of a component grid, a refined grid should be defined within the component to further define the region of wear and provide locations for documentation of measurements. If unacceptable thinning is found at the boundary of a grid, the grid should be expanded in the direction of thinning until thickness readings become acceptable.

IV-5.4 Acceptance Standards

The Code-required wall thickness t_m of each component inspected shall be determined in accordance with para. 104 of the Code. The required wall thickness should include consideration of the minimum wall thickness required to satisfy all of the stress requirements of para. 104.

A calculation of predicted wall thickness t_p at the next examination should be performed for all components with measured wall thickness less than 87.5% of nominal wall thickness t_n.

(A) All components with t_p at the next examination of less than t_m or 70% t_n, whichever is greater, should be identified. Additional examinations during the current inspection should be performed for:

(1) equivalent piping items in other trains when the system containing the subject piping item consists of more than one train;

(2) Additional components in the same system/pipeline which have been determined to be susceptible to E/C.

When (1) and (2) above reveal additional components which meet the criteria of (a)(1) above, this process should be repeated until no additional components meet the criteria.

(B) All components with predicted wall thickness at the next examination of less than or equal to the greater of t_m or $0.3t_n$ shall be repaired, replaced, or evaluated for acceptability for continued service. An acceptable evaluation procedure has been provided in [2] and [3] of para. IV-5.6.

IV-5.5 Repair/Replacement Procedures

Repair or replacement of piping components should be performed in accordance with Appendix V. Erosion rates for chrome-molybdenum alloys are significantly lower than carbon steels and virtually nonexistent for stainless steels. When replacement is chosen, consideration of the increased resistance of alloy steels to E/C should be included in the selection of the replacement component material. The use of backing rings, which can create areas of local turbulence which will promote E/C damage, should be avoided.

NONMANDATORY APPENDIX V[1]
RECOMMENDED PRACTICE FOR OPERATION, MAINTENANCE, AND MODIFICATION OF POWER PIPING SYSTEMS

FOREWORD

The B31.1 Power Piping Code prescribes minimum requirements for the construction of power and auxiliary service piping within the scope of para. 100.1. The Code, however, does not provide rules or other requirements for a determination of optimum system function, effective plant operations, or other measures necessary to assure the useful life of piping systems. These concerns are the responsibility of the designer and, after construction turnover, the Operating Company personnel responsible for plant activities.

Past experience has shown that a need exists for the definition of acceptable plant practices for achieving both reliable service and a predictable life in the operation of power piping systems. This nonmandatory Appendix is intended to serve that purpose. For this objective, Appendix V is structured in three parts that recognize and address the following basic concepts.

operation: the design of a piping system is based on specified service requirements and operating limitations. Subsequent operation within these defined limits is assumed and, for some systems, will be important for an acceptable service life.

maintenance: the design of a piping system assumes that reasonable maintenance and plant service will be provided. The lack of this support will, in some cases, introduce an increasing degree of piping system life uncertainty.

modifications: future modifications of a piping system or its operational functions are not assumed in original design unless specified. Modifications must not invalidate the integrity of a piping system design.

The practices in Appendix V are recommended for all plants and systems within the scope of the Power Piping Code, both for new construction and for existing plants in operation. An acceptable implementation of these or equivalent practices will be beneficial for new systems. The application of these practices is recommended for power piping systems in operating plants.

The recommended practices in this Appendix define minimum requirements for establishing a program to accommodate the basic considerations for piping system operation, maintenance, service, modification, and component replacement.

A record-keeping program is prescribed that can serve as a point of reference for analyzing piping system distortions or potential failures. Such a program is intended to identify distortions or failures and assure compatibility between the materials and components of existing piping systems with those portions undergoing repair, replacement, or modification.

DEFINITIONS[2]

Code: ASME Code for Pressure Piping, ASME B31.1 Power Piping

component: equipment, such as vessel, piping, pump, or valve, which are combined with other components to form a system

critical piping systems: those piping systems which are part of the feedwater-steam circuit of a steam generating power plant, and all systems which operate under two-phase flow conditions. Critical piping systems include runs of piping and their supports, restraints, and root valves. Hazardous gases and liquids, at all pressure and temperature conditions, are also included herein. The Operating Company may, in its judgment, consider other piping systems as being critical in which case it may consider them as part of this definition.

examination: an element of inspection consisting of investigation of materials, components, supplies, or services to determine conformance to those specified requirements which can be determined by such investi-

[1] Nonmandatory Appendices are identified by a Roman numeral; mandatory Appendices are identified by a letter. Therefore, Roman numeral I is not used in order to avoid confusion with the letter I.

[2] The definitions pertain specifically to this Appendix.

Wed Feb 02 00:56:01 2005

gation. Examination is usually nondestructive and includes simple physical manipulation, gaging, and measurement.

failure: that physical condition which renders a system, component, or support inoperable

maintenance: actions required to assure reliable and continued operation of a power plant, including care, repair, and replacement of installed systems

modification: a change in piping design or operation and accomplished in accordance with the requirements and limitations of the Code

Operating Company: the Owner, user, or agent acting on behalf of the Owner who has the responsibility for performing the operations and maintenance functions on the piping systems within the scope of the Code

procedure: a document that specifies or describes how an activity is to be performed. It may include methods to be employed, equipment or materials to be used, and sequences of operations

qualification (personnel): demonstration of the abilities gained through training and/or experience that enable an individual to perform a required function

renewal: that activity which discards an existing component and replaces it with new or existing spare materials of the same or better qualities as the original component

repair: to restore the system or component to its designed operating condition as necessary to meet all Code requirements

specification: a set of requirements to be satisfied by a product, material, or process, indicating, whenever appropriate, the procedure by means of which it may be determined whether the requirements given are satisfied

V-1.0 GENERAL

V-1.1 Application

V-1.1.1 This Appendix recommends minimum requirements for programs to operate and maintain ASME B31.1 Power Piping systems and also for the repairs to these systems.

V-1.1.2 Local conditions and the location of piping systems (such as indoors, outdoors, in trenches, or buried) will have considerable bearing on the approach to any particular operating and maintenance procedure. Accordingly, the methods and procedures set forth herein serve as a general guide. The Operating Company is responsible for the inspection, testing, operation and maintenance of the piping system and shall have the responsibility for taking prudent action to deal with inherent plant conditions.

V-1.2 Conformance

V-1.2.1 When conformance with time periods for examination recommended in this document is impractical, an extension may be taken if an evaluation demonstrates that no safety hazard is present.

V-1.3 Requirements

V-1.3.1 This Appendix recommends that the following listed items be established and implemented:

(A) complete design and installation records of the "as built" large bore piping systems, including expansion joints, hangers, restraints, and other supporting components. The Operating Company shall define those sizes considered to be large bore pipe.

(B) records of operation and maintenance history;

(C) programs for periodic inspection and monitoring;

(D) procedures for reporting and analyzing failures;

(E) procedures for maintenance, repairs, and replacements;

(F) procedures for abandoning piping systems and for maintaining piping systems in and out-of-service condition; and

(G) procedures for assuring that all personnel engaged in direct maintenance of such piping systems as defined in para. V-4.2.1(C) are qualified by training or experience for their tasks or work.

V-2.0 OPERATING AND MAINTENANCE PROGRAM

V-2.1

Each Operating Company shall develop an operating and maintenance program comprising a series of written procedures, keeping in mind that it is not possible to prescribe a single set of detailed operating and maintenance procedures applicable to all piping systems. The operating and maintenance procedures shall include: personnel qualifications as defined by the Operating Company, material history and records, and supplementary plans to be implemented in case of piping system failures.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:01 2005

V-2.2

Each plant should maintain and file the following documentation that exists for each unit:

(A) current piping drawings;

(B) construction isometrics (or other drawings) that identify weld locations;

(C) pipeline specifications covering material, outside diameter, and wall thickness;

(D) flow diagrams;

(E) support drawings;

(F) support setting charts;

(G) records of any piping system modifications;

(H) material certification records;

(I) records of operating events that exceed design criteria of the piping or supports;

(J) valve data;

(K) allowable reactions at piping connections to equipment;

(L) welding procedures and records.

V-3.0 REQUIREMENTS OF THE OPERATING, MAINTENANCE, AND MODIFICATION PROCEDURES

V-3.1

The Operating Company shall have procedures for the following:

(A) to perform normal operating and maintenance work. These procedures shall include sufficiently detailed instructions for employees engaged in operating and maintaining the piping systems,

(B) to prescribe action required in the event of a piping system failure or malfunction that may jeopardize personnel safety, safe operation, or system shutdown. Procedures shall consider:

(B.1) requirements defined for piping system operations and maintenance and should include failure conditions under which shutdown may be required. Procedures should include both the action required and the consequence of the action on related systems or subsystems.

(B.2) the designation of personnel responsible for the implementation of required action, and minimum requirements for the instruction, training, and qualification of these personnel.

(C) to periodically inspect and review changes in conditions affecting the safety of the piping system. These procedures shall provide for a system of reporting to a designated responsible person in order that corrective measures may be taken.

(D) to assure that modifications are designed and implemented by qualified personnel and in accordance with the provisions of the Code;

(E) to analyze failures to determine the cause and develop corrective action to minimize the probability of recurrence;

(F) to intentionally abandon unneeded piping systems, or portions thereof, and to maintain those which are out of service for extended periods of time as defined by the Operating Company;

(G) to ensure that instruction books and manuals are consulted in performing maintenance operations;

(H) to log, file, maintain, and update instruction books;

(I) to log operating and maintenance records; and

(J) to periodically review and revise procedures as dictated by experience and changes in conditions.

V-4.0 PIPING AND PIPE SUPPORT MAINTENANCE PROGRAM AND PERSONNEL REQUIREMENTS

V-4.1 Maintenance Program

V-4.1.1 The maintenance program shall include the following listed features:

(A) a purpose for the program;

(B) the frequency for performing all elements of maintenance and inspection listed in the program;

(C) generic requirements as related to initial hanger positions at time of unit startup, changes and adjustments in hanger positions at periodic inspections, and review of manufacturer's instruction and maintenance manuals applicable to components included in the program;

(D) updating and modification as may be desirable by reason of Code revisions and technological advances or other considerations;

(E) steps to keep maintenance and inspection personnel aware of program revisions.

V-4.2 Personnel

V-4.2.1 To the extent necessary for conformance with the maintenance program of the Operating Company, only qualified and trained personnel shall be utilized for the following:

(A) observation, measurement, and recording the position of piping systems and hanger readings;

(B) adjustment of hangers and all other components of support and restraint systems; and

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:02 2005

(C) repair and periodic maintenance routines including, but not limited to:

(C.1) routine piping assembly, including welding of integral attachments;

(C.2) mechanical repair of valves, traps, and similar types of piping specialty components, including packings;

(C.3) removal and replacement of piping insulation;

(C.4) lubrication of applicable piping and hanger components, such as valves and constant supports, maintenance of fluid levels in hydraulic restraints; and stroking of hydraulic and mechanical dynamic restraints (snubbers).

(C.5) routine surveillance for changing conditions including changes in position of piping and settings of piping hangers and shock suppressors (snubbers).

V-4.2.2 Review of records and failure reports and decisions concerning corrective actions or repairs should be carried out by or under the direction of a qualified piping engineer.

V-4.2.3 Welding and Heat Treatment Personnel

(A) Welders shall be qualified to approved welding procedures. Qualification of weld procedures and the qualification performance of the welder shall be in accord with the requirements of para. 127.5.

(B) Trained personnel shall perform preheat and postheat treatment operations as described in the requirements of para. 131.

V-4.2.4 Examination, Inspection, and Testing Personnel. Trained personnel shall perform nondestructive examinations (NDE), including visual inspections and leak tests (LT), all in accord with the requirements of para. 136.

V-5.0 MATERIAL HISTORY

V-5.1 Records

V-5.1.1 Records shall be maintained to the extent necessary to permit a meaningful failure analysis or reconstruction of a prior condition should the need arise. These records may be limited to those systems identified as critical as defined herein.

V-5.1.2 The records listed below are recommended for inclusion in the materials history and, where possible, be traceable to specific components in a piping system:

(A) procurement documents including specifications;

(B) original service date and operating conditions;

(C) list of materials, both original and replacement, with system location and material specification;

(D) physical and mechanical properties from material test reports (if available), including, the following as applicable:

(D.1) Manufacturer's Material Test Reports or Certificate of Conformance;

(D.2) chemical analysis;

(D.3) impact tests;

(D.4) special processing, i.e., heat treatment, mechanical working, etc.

(E) wall thicknesses where available from construction or maintenance records, including design minimum wall requirements;

(F) record of alterations or repairs;

(G) nondestructive examination reports (including radiographs, if available);

(H) special coatings, linings, or other designs for corrosion or erosion resistance;

(I) failure reports.

V-5.2 Failure Reports

V-5.2.1 The Operating Company shall be responsible for investigating all material failures in critical piping systems. The cause for failure shall be established. A report of the results of this investigation shall be included in the material history file and shall, as a minimum, contain the following information:

(A) summary of design requirements;

(B) record of operating and test experience of failed components;

(C) any previous history of the component;

(D) any special conditions (corrosion, extraordinary loads, thermal excursions, etc.) which may have contributed to failure;

(E) conclusions as to cause;

(F) recommendations for corrective actions to minimize recurrence;

(G) corrective actions that were taken, including verification of satisfactory implementation;

(H) corrective action details and recommendations, if any, for similar action in other piping systems.

V-5.3 Restoration after Failure

V-5.3.1 Defective component(s) shall be repaired or replaced with comparable or upgraded materials permissible by this Code after evaluation of the failure and taking into account conclusions as to cause. Even when materials are replaced by same or upgraded items, a formal failure report should follow as in para. V-5.2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:03 2005

V-5.3.2 Care shall be exercised when replacing system components to ensure no parts of the system are overstressed. The stresses in the repaired system shall be equal to or less than the original stresses unless analysis permits increased stresses. During the replacement of the component, the piping system should be temporarily supported or restrained on both sides of the component to be removed so as to maintain its as-found cold position until the component(s) is (are) installed. If the desired piping position cannot be maintained, an analysis shall be made to determine the reason for the problem. A new stress analysis may be necessary. Care shall be exercised when working on a system that has been subjected to self-springing or cold pull.

V-5.3.3 Weld preparations and fit-up of the weld joints shall meet the requirements of Chapter V.

V-5.3.4 Welding procedures and preheat/postheat treatments of the weld joints shall meet the minimum requirements of Chapter V.

V-5.4 Weld Records

V-5.4.1 Records shall be maintained for all welds in critical piping systems. These records shall include, but not be limited to, the following:

(A) original installation records, where available;

(B) repair and modification welds including excavation location and depth;

(C) welding procedures and qualification tests;

(D) nondestructive examination reports;

(E) heat treatment performed.

V-5.5 Inspection Program for Materials With Adverse History

V-5.5.1 Materials which have been reported to the industry to exhibit an adverse performance under certain conditions shall be given special attention by the Operating Company through a program of planned examination and testing. This program shall include the development of procedures for repair or replacement of the material when the Operating Company determines that such action is necessary.

V-5.5.2 Methods of surveillance and analysis shall be determined by the Operating Company.

V-5.5.3 The frequency of the material inspection shall also consider the expected service life of the component.

V-5.6 Nondestructive Examination

V-5.6.1 Nondestructive examinations used to investigate any suspect materials or problem areas shall be in accordance with Chapter VI.

V-6.0 PIPING POSITION HISTORY

V-6.1 General

V-6.1.1 Movements of critical piping systems from their design locations shall be used to assess piping integrity. The Operating Company shall have a program requiring such movements be taken on a periodic basis along with a procedure precluding the unnecessary removal of insulation when measurements are taken; refer to para. V-6.3. Piping system movement records shall be maintained. The Operating Company shall evaluate the effects of position changes on the safety of the piping systems and shall take appropriate corrective action.

V-6.1.2 Although the Code recognizes that high temperature piping systems seldom return to their exact original positions after each heat cycle due to relaxation, critical piping systems as defined herein, must be maintained within the bounds of engineering evaluated limitations.

V-6.2 Visual Survey

V-6.2.1 The critical piping systems shall be observed visually, as frequently as deemed necessary, and any unusual conditions shall be brought to the attention of personnel as prescribed in procedures of para. V-3.1. Observations shall include determination of interferences with or from other piping or equipment, vibrations, and general condition of the supports, hangers, guides, anchors, supplementary steel, and attachments, etc..

V-6.3 Piping Position Markers

V-6.3.1 For the purpose of easily making periodic position determinations, it is recommended that permanent markings on critical piping systems be made by providing markings or pointers attached to piping components. The position of these markings or pointers should be noted and recorded with respect to stationary datum reference points.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:04 2005

V-6.3.2 Placement of pointers shall be such that personnel safety hazards are not created.

V-6.4 Hangers and Supports on Critical Piping Systems and Other Selected Systems

V-6.4.1 Hanger position scale readings of variable and constant support hangers shall be determined periodically. It is recommended that readings be obtained while the piping is in its fully hot position, and if practical, when the system is reasonably cool or cold sometime during the year as permitted by plant operation. Pipe temperature at time of reading hangers shall be recorded.

V-6.4.2 Variable and constant support hangers, vibration snubbers, shock suppressors, dampeners, slide supports and rigid rod hangers shall be maintained in accordance with the limits specified by the manufacturers and designers. Maintenance of these items shall include, but not necessarily be limited to, cleaning, lubrication and corrosion protection. All dynamic restraints (snubbers) should be stroked periodically.

V-6.5 Records on Critical Piping Systems and Other Selected Systems

V-6.5.1 Pipe location readings and travel scale readings of variable and constant support hangers shall be recorded on permanent log sheets in such a manner that will be simple to interpret. See Fig. V-6.5 for suggested hanger record data sheet. Records of settings of all hangers shall be made before the original commercial operation of the plant. Log sheets should be accompanied by a pipe support location plan or piping system drawing with hanger mark numbers clearly identified. In addition, records are to be maintained showing movements of or in expansion joints including records of hot and cold or operating and shutdown positions, particularly those not equipped with control rods or gimbals.

V-6.6 Recommendations

V-6.6.1 After complete examination of the records (para. V-6.5), recommendations for corrective actions needed shall be made by a piping engineer or a qualified responsible individual or organization. Repairs and/or modifications are to be carried out by qualified maintenance personnel for all of the following items:

(A) excessively corroded hangers and other support components;

(B) broken springs or any hardware item which is part of the complete hanger or support assembly;

(C) excessive piping vibration; valve operator shaking or movements;

(D) piping interferences;

(E) excessive piping deflection which may require the installation of spring units having a greater travel range;

(F) pipe sagging which may require hanger adjustment or the reanalysis and redesign of the support system;

(G) hanger unit riding at either the top or the bottom of the available travel;

(H) need for adjustment of hanger load carrying capacity;

(I) need for adjustments of hanger rods or turnbuckle for compensation of creep or relaxation of the piping,

(J) loose or broken anchors;

(K) inadequate clearances at guides;

(L) inadequate safety valve vent clearances at outlet of safety valves;

(M) any failed or deformed hanger, guide, U-bolt, anchor, snubber, or shock absorber, slide support, dampener, or supporting steel;

(N) unacceptable movements in expansion joints;

(O) low fluid levels in hydraulic pipe restraints.

V-7.0 PIPING CORROSION

V-7.1 General

V-7.1.1 This section pertains to the requirements for inspection of critical piping systems that may be subject to internal or external corrosion-erosion, such as buried pipe, piping in a corrosive atmosphere, or piping having corrosive or erosive contents. Requirements for inspection of piping systems in order to detect wall thinning of piping and piping components due to erosion/corrosion, or flow-assisted corrosion, is also included. Erosion/corrosion of carbon steel piping may occur at locations where high fluid velocity exists adjacent to the metal surface, either due to high velocity or the presence of some flow discontinuity (elbow, reducer, expander, tee, control valve, etc.) causing high levels of local turbulence. The erosion/corrosion process may be associated with wet steam or high purity, low oxygen content water systems. Damage may occur under both single and two-phase flow conditions. Piping systems that may be damaged by erosion/corrosion include, but are not limited to, feedwater, condensate, heater drains, and wet steam extraction lines. Mainte-

(1) Hanger size to be taken from hanger fabrication drawing.
(2) For constant support and variable support types indicate by CS or VS. For rigid, anchor, guide, sliding, or other type support, indicate by letter R, A, G, or S, respectively.
(3) Elevation of center line of pipe after cold springing and final hanger settings with line cold.
(4) "0" indicated the highest scale position with "5" being the midpoint, and "10" being the lowest scale position.

FIG. V-6.5 HANGER RECORD SHEET

nance of corrosion control equipment and devices is also part of this section. Measures in addition to those listed herein may be required.

V-7.1.2 Where corrosion is cited in this section, it is to be construed to include any mechanism of corrosion and/or erosion. Recommended methods for monitoring and detection, acceptance standards, and repair/replacement procedures for piping components subjected to various erosion/corrosion mechanisms, including flow-assisted corrosion, are provided in nonmandatory Appendix IV.

V-7.1.3 Guidance for the evaluation and monitoring of carbon steel piping susceptible to erosion/corrosion (flow assisted corrosion) is provided in Appendix IV, para. IV-5.0.

V-7.2 Procedures

V-7.2.1 The Operating Company shall establish procedures to cover the requirements of this paragraph.

V-7.2.2 Procedures shall be carried out by or under the direction of persons qualified by training or experience in corrosion control and evaluation of piping systems for corrosion damage.

V-7.2.3 Procedures for corrosion control shall include, but not be limited to the following:

(A) maintenance painting to resist external ambient conditions;

(B) coating and/or wrapping for external protection of buried or submerged systems;

(C) lining to resist internal corrosion from system fluid when applicable;

(D) determining the amount of corrosion or erosion of the piping system internals caused by the flowing fluid;

(E) determining the amount of external corrosion caused by ambient conditions, such as atmosphere, buried in soil, installed in tunnels or covered trenches, and submerged underwater;

(F) preparing records which shall include all known leakage information, type of repair made, location of cathodically protected pipe, and the locations of cathodic protection facilities including anodes; and

(G) examining records from previous inspection and performing additional inspections where needed for historical records.

V-7.3 Records

V-7.3.1 Tests, surveys, and inspection records to indicate the adequacy of corrosion control shall be maintained for the service life of the piping system. This should include records of measured wall thickness and rates of corrosion.

V-7.3.2 Inspection and maintenance records of cathodic protection systems shall be maintained for the service life of the protected piping.

V-7.3.3 Observations of the evidence of corrosion found during maintenance or revision to a piping system shall be recorded.

V-7.4 Examination of Records

V-7.4.1 Records shall be examined and evaluated by trained personnel.

V-7.4.2 Where inspections or leakage history indicate that active corrosion is taking place to the extent that a safety hazard is likely to result, applicable portions of the system shall be replaced with corrosion resistant materials or with materials which are protected from corrosion, or other suitable modifications shall be made.

V-7.5 Frequency of Examination

V-7.5.1 Within 3 years after original installation, each piping system shall be examined for evidence of corrosion in accordance with the requirements established by the Operating Company's procedures. Piping in severe service or environmental conditions should be inspected initially within a time frame commensurate with the severity of the service or environment. Corrective measures shall be taken if corrosion is above the amount allowed for in the original design.

V-7.5.2 Continued examination shall be made at intervals based upon the results of the initial inspection, but not to exceed 5 years, with corrective measures being taken each time that active corrosion is found.

V-7.5.3 Examination for evidence of internal corrosion shall be made by one of the following:

(A) drilled hole with subsequent plugging;

(B) ultrasonic test for wall thickness determination;

(C) removal of representative pipe section at flange connections or couplings;

(D) removal of short section of pipe;

(E) radiography for evidence of wall thinning;

(F) borescope or videoprobe examination; or

(G) a method equivalent to those above.

V-7.5.4 Examinations for evidence of external corrosion shall be made after removal of covering, insulation or soil on a representative short section of the piping system taking into consideration varying soil conditions.

V-8.0 PIPING ADDITION TO EXISTING PLANTS

V-8.1 Piping Classification

V-8.1.1 Piping and piping components which are replaced, modified, or added to existing piping systems are to conform to the edition and addenda of the Code used for design and construction of the original systems, or to later Code editions or addenda as determined by the Operating Company. Any additional piping systems installed in existing plants shall be considered as new piping and shall conform to the latest issue of the Code.

V-8.2 Duplicate Components

V-8.2.1 Duplicates of original components and materials are permitted for permanent replacements, provided the renewal is a result of reasonable wear and not the result of the improper application of the material, such as temperature and corrosive environment.

V-8.3 Replacement Piping and Piping Components

V-8.3.1 Where replacement components differ from the original components with respect to weight, dimensions, layout, or material, the design of the affected piping system shall be rechecked for the following design considerations.

(A) Hangers and supports shall be adequate for additional or altered distribution of weight. They shall accommodate the flexibility characteristics of the altered piping system.

(B) Changes in stresses imposed on both existing and replacement components of the piping shall be evaluated and compensation shall be made to prevent overstress in any part of the entire altered piping system.

V-9.0 SAFETY, SAFETY RELIEF, AND RELIEF VALVES

V-9.1 General

V-9.1.1 This section is applicable to safety, safety relief, and relief valve installations (see Appendix II for definitions of these terms.) Except as otherwise noted, all reference to "safety" valve(s) shall be considered to include all three types. Safety valves shall be maintained in good working condition. Also, discharge pipes and their supports shall be inspected routinely and maintained properly. Any evidence of blowback at the drip pan of open safety valve vent systems should be noted and its cause determined and corrected.

V-9.2 Testing and Adjustment

V-9.2.1 Testing of safety valves for pressure setting shall be in accordance with written procedures which incorporate the requirements of regulatory agencies and manufacturer's instructions. Testing should be performed just prior to a planned outage so that any required repair or maintenance, except spring and blowdown ring adjustments, can be performed during the outage, thereby assuring tight valves upon return to service.

V-9.2.2 The setting or adjustment of safety valves shall be done by personnel trained in the operation and maintenance of such valves. Safety valves shall be tested after any change in setting of the spring or blowdown ring. Appropriate seals should be used to assure that there is no unauthorized tampering with valve settings. Repairs to safety valves and disassembly, reassembly, and/or adjustments affecting the pressure relief valve function, which are considered a repair, should be performed by an authorized repair organization.[3]

V-9.3 Operation

V-9.3.1 The precautions stated in the manufacturer's operating manual or instruction books shall be followed when operating safety valves. In general, these precautions will include the following.

(A) Hand lifting is permitted. Assistance, as required, may be accomplished by the use of small wires or chains.

(B) Striking or hammering the valve body shall not be permitted. Only the hand-test lever shall be used.

(C) Attempts to stop leakage through the valve seat shall not be made by compressing the spring.

V-10.0 DYNAMIC LOADING

V-10.1 Water Hammer

V-10.1.1 Water hammer includes any water or other liquid transient event such as pressure surge or impact loading resulting from sudden or momentary change in flow or flow direction.

[3] Examples of organizations which may be authorized by the owner or by the local jurisdiction to perform repairs on safety valves include but are not limited to the original valve manufacturer or a repair organization which holds a National Board of Boiler and Pressure Vessel Inspectors (NB-23) VR stamp.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:05 2005

V-10.1.2 Should significant water hammer develop during plant operation, the cause should be determined and corrective action taken. Water hammer could be the result of an incorrectly sloped pipe intended for steam condensate drainage. Water hammer in piping systems may cause damage to hangers, valves, instrumentation, expansion joints, piping and equipment integral with the piping. The Operating Company should develop procedures to deter water hammer and to determine when corrective action is necessary.

V-10.1.3 Water hammer problems resulting from accumulated condensate in a steam line cannot be solved simply by adding restraints. Corrective action may include changing line slopes, adding drain pots, adding warm-up lines around valves, checking for leaking desuperheaters, faulty electrical controls on automatic drains, etc.

V-10.1.4 Water hammer due to column separation in feedwater or booster pump suction piping results when the deaerator pegging pressure is not maintained. This type of water hammer can be particularly severe and requires prompt attention to control and reduce it.

V-10.1.5 As a priority, corrective action should address the cause of waterhammer first. If such corrective action is ineffective in reducing the effects of water hammer to acceptable levels, installation of restraints may be necessary to limit piping displacements and/or damage from fatigue.

V-10.2 Steam Hammer

V-10.2.1 Dynamic loads due to rapid changes in flow conditions and fluid state in a steam piping system are generally called steam hammer loads. Piping response to these momentary unbalanced loads can be significant in high pressure steam systems, such as main steam, hot and cold reheat steam, bypass and auxiliary steam systems that are subject to rapid interruption or establishment of full steam flow.

V-10.2.2 The Operating Company should develop procedures to determine any adverse effects of steam hammer, such as excessive pipe movement, damage to hangers and restraints, and high pipe stress and reactions at pipe connections to equipment. Where such movements, stresses, and reactions exceed safe limits or allowable loadings, a program of remedial action should be implemented.

V-11.0 HIGH TEMPERATURE CREEP

V-11.1 General

V-11.1.1 Catastrophic failure, including rupture, can occur due to excessive creep strains resulting from operation of the piping above design pressure, or temperatures, or both, for extended periods of time. The expected life of a piping system operating in the creep range can be reduced significantly through prolonged exposure to pressure or temperature, particularly temperature, above design values. Paragraph 102.2.4 provides criteria for occasional short operating periods at higher than design pressure or temperature.

V-11.1.2 This section provides the minimum requirements for evaluating critical piping systems in order to detect creep damage and to assist in predicting the remaining life under expected operating conditions. The remaining useful life may be estimated by determining the extent of creep damage sustained by the pipe.

V-11.2 Procedures

V-11.2.1 The Operating Company shall establish procedures to cover the requirements of this paragraph.

V-11.2.2 The procedures shall be carried out by or under the direction of persons qualified by training or experience in metallurgical evaluation of high temperature creep effects in power plant piping.

V-11.2.3 An evaluation program to determine the extent of creep damage and estimate remaining life of high temperature piping shall be carried out in three phases, as follows:

(A) review of material specifications, design stress levels, and operating history;

(B) indirect measurements to determine extent of creep damage. These would include diametral measurements to detect creep swelling. In addition, dye penetrant, magnetic particle, ultrasonic, and radiographic methods may be used to detect internal and surface cracks.

(C) examination of the microstructure to determine the degree of material degradation. This can be performed by replication techniques or by metallography using specimens obtained by boat-sampling or trepanning.

V-11.3 Records

V-11.3.1 Records of creep damage evaluation survey findings shall be maintained for the service life of high temperature piping systems operating in the creep range.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:06 2005

V-11.4 Examination of Records

V-11.4.1 Records of creep damage surveys and test reports shall be examined by personnel qualified by training and experience to evaluate and interpret NDE and metallographical studies.

V-11.4.2 Where surveys and inspections of critical piping systems indicate that high temperature creep damage has progressed to an unacceptable level, affected portions of the piping system shall be replaced.

V-11.5 Frequency of Examination

V-11.5.1 Periodically, all critical piping systems operating within the creep range shall be examined for evidence of high temperature creep damage. Particular attention shall be given to welds.

V-11.5.2 The examination shall be repeated at periodic intervals which shall be established on the basis of earlier survey findings, operating history, and severity of service.

V-12.0 RERATING PIPING SYSTEMS

V-12.1 Conditions

V-12.1.1 An existing piping system may be rerated for use at a higher pressure and/or temperature if all of the following conditions are met:

(A) a design analysis shall be performed to demonstrate that the piping system meets the requirements of the Code at the new design conditions;

(B) the condition of the piping system and support/restraint scheme shall be determined by field inspections and the examination of maintenance records, manufacturer's certifications, and/or other available information to ensure conformance with the Code requirements for the new design conditions;

(C) necessary repairs, replacements, or alterations to the piping system are made to conform with the requirements prescribed in (A) and (B) above;

(D) the system has been leak tested to a pressure equal to or greater than that required by the Code for a new piping system at the new design conditions;

(E) the rate of pressure and temperature increase to the higher maximum allowable operating conditions shall be gradual so as to allow sufficient time for periodic observations of the piping system movements and leak tightness;

(F) records of investigations, work performed, and pressure tests conducted in rerating the piping systems shall be preserved for the service life of the piping systems; and

(G) all safety valves, relief valves, and other pressure relieving devices must be examined, and recertified for the new pressure/temperature design conditions. Capacity of relieving equipment shall be investigated if the design pressure and/or temperature are changed in rerating a piping system.

NONMANDATORY APPENDIX VI[1]
APPROVAL OF NEW MATERIALS

The ASME B31.1 Committee considers requests for adoption of new materials desired by the owner/user or fabricator, manufacturer, installer, assembler of piping or piping components constructed to the Code. In order for the material to receive proper consideration, information and data are required to properly categorize the material. In general this information and data include, but are not necessarily limited to the following:

(A) the chemical composition of the material including those elements that establish the characteristics and behavior of the material;

(B) the mechanical properties of the material, including tensile test data, ductility data, and other special mechanical test data, which will assist the Committee in its review of the material and its application:

(B.1) tensile test data (per ASTM E 21), including both ultimate tensile strength and yield strength, at room temperature and at 100°F or 50°C intervals to a temperature at least 100°F higher than the intended use of the material.

(B.2) when creep properties are expected to limit the allowable stress, creep and creep rupture data at temperature intervals of 100°F or 50°C are also required. Such data should be for four or more time intervals, one of which should be longer than 2000 hr but less than 6000 hr, and one of which should be longer than 6000 hr.

(C) if the material is to be used in welded construction, data from actual welding tests made in accordance with Section IX of the ASME Boiler and Pressure Vessel Code should be submitted. Welding test data should include:

(C.1) the welding processes and weld filler metal(s) intended for the fabrication of the material;

(C.2) all-weld-metal tensile test data for temperatures representative of intended service;

(C.3) any special restrictions on the welding of the material;

(C.4) the appropriate preheat and postweld heat treatment, if any, which will be given the material. If postweld heat treatment results in embrittlement of the material, the significance of such treatments with substantiating data should be forwarded. Toughness data on weld metal and heat affected zone in the as-welded and postweld heat treated conditions, when appropriate, should be submitted.

(D) where the material is intended for special applications, requires special handling or special welding procedures, or has known limitations or susceptibility to failure in certain services, precautionary requirements and information should also be submitted for review by the Committee.

(E) applicable product form(s) of the material, such as sheet, strip, plate, bars, shapes, seamless or welded pipe or tube forgings, castings, etc., for which application is to be considered must be identified.

The general data recommended should be submitted on a minimum of three heats, preferably commercial heats, of the material. Where the range of chemical composition affect the mechanical properties, the heats selected should cover both the high and low range of the effective chemical elements to show the effect on the mechanical properties. Any special heat treatment, whether applied by the material supplier or the fabricator, should be applied to the test pieces used to obtain the data.

If the material is covered by an ASTM specification, the specification number(s) and grade(s) involved must be identified in the application. If the material is not covered by an ASTM specification, application must be made to ASTM for specification coverage of this material.

Should there be a need for Code use prior to the inclusion of the material in ASTM specifications, the Committee will consider issuing a Code Case.

In addition to the information and data noted above, the Committee should be provided with an indication of user need, a copy of the letter to ASTM requesting specification coverage, and sufficient information for the Committee to modify an appropriate existing ASTM specification to establish the material specification requirements for the material product form.

When the new material is a minor modification of a material which is currently accepted by the Code,

[1] Nonmandatory appendices are identified by a roman numeral; mandatory appendices are identified by a letter. Therefore, roman numeral I is not used in order to avoid confusion with the letter I.

the data required may be reduced with the concurrence of the Committee. When the data supplied are insufficient for an adequate evaluation, the Committee will request additional data. Such requests will be returned, indicating those areas in which additional information is required.

NONMANDATORY APPENDIX VII[1]
PROCEDURES FOR THE DESIGN OF RESTRAINED UNDERGROUND PIPING

FOREWORD

The Code contains rules governing the design, fabrication, materials, erection, and examination of power piping systems. Experience over the years has demonstrated that these rules may be conservatively applied to the design and analysis of buried piping systems. However, the ASME B31.1 rules were written for piping suspended in open space, with the supports located at local points on the pipe. Buried piping, on the other hand, is supported, confined, and restrained continuously by the passive effects of the backfill and the trench bedding. The effects of continuous restraint cannot be easily evaluated by the usual methods applied to exposed piping, since these methods cannot easily accommodate the effects of bearing and friction at the pipe/soil interface. Accordingly, this Appendix has been prepared to illustrate and clarify the application of Code rules to restrained buried piping.

All components in the buried piping system must be given consideration, including the building penetrations, branches, bends, elbows, flanges, valves, grade penetrations, and tank attachments. It is assumed that welds are made in accordance with this Code and that appropriate corrosion protection procedures are followed for buried piping.

This Appendix provides analytic and nomenclature definition figures to assist the designer, and is not intended to provide actual design layout. Sample calculations for various configurations of semirigid buried piping have been provided at the end of the text to assist the designer in the application of these procedures.

VII-1.0 SCOPE AND DEFINITIONS

VII-1.1 Scope

The scope of this Appendix is confined to the design of buried piping as defined in para. VII-1.2. Thermal expansion in buried piping affects the forces, the resulting bending moments and stresses throughout the burried portions of the system, particularly at the anchors, building penetrations, buried elbows and bends, and branch connections, and it is the designer's responsibility to consider these forces. This Appendix, however, deals only with the buried portions of the system, and not the complete system.

The design and analysis of buried piping requires that careful attention be paid to:

(A) all loads acting on the system;

(B) the forces and the bending moments in the piping and piping components resulting from the loads;

(C) the loading and stress criteria;

(D) general design practices.

VII-1.2 Definitions

confining pressure: the pressure imposed by the compacted backfill and overburden on a buried pipe. Confining pressure is assumed to act normal to the pipe circumference.

flexible coupling: a piping component that permits a small amount of axial or angular movement while maintaining the pressure boundary

friction: the passive resistance of soil to axial movement. Friction at the pipe/soil interface is a function of confining pressure and the coefficient of friction between the pipe and the backfill material. Friction forces exist only where there is actual or impending slippage between the pipe and soil

influence length: that portion of a transverse pipe run which is deflected or "influenced" by pipe thermal expansion along the axis of the longitudinal run

modulus of subgrade reaction: the rate of change of soil bearing stress with respect to compressive deformation of the soil. It is used to calculate the passive spring rate of the soil

[1] Nonmandatory appendices are identified by a roman numeral; mandatory appendices are identified by a letter. Therefore, roman numeral I is not used in order to avoid confusion with the letter I.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:08 2005

penetration: the point at which a buried pipe enters the soil either at grade or from a wall or discharge structure

settlement: the changes in volume of soil under constant load which results in the downward movement, over a period of time, of a structure or vessel resting on the soil

virtual anchor: a point or region along the axis of a buried pipe where there is no relative motion at the pipe/soil interface

VII-1.3 Nomenclature

a, b, c = quadratic equation functions
A = cross sectional metal area of pipe, in.[2]
A_c = surfaced area of a 1-in. long pipe segment, in.[2]
B_d = trench width at grade, in.
C_D = soil bearing parameter from Table VII-3.2.3, dimensionless
C_k = horizontal stiffness factor for backfill [8],[2] dimensionless
D = pipe outside diameter, in.
dL = length of pipe element, in.
E = Young's modulus for pipe, psi
f = unit friction force along pipe, lb/in.
f_{min}, f_{max} = minimum, maximum unit friction force on pipe, lb/in.
F_f = total friction force along effective length, lb
F_{max} = maximum axial force in pipe, lb
H = pipe depth below grade, in.
I = pipe section moment of inertia, in.[4]
k = soil modulus of subgrade reaction, psi
k_h = soil horizontal modulus of subgrade reaction, psi
$k_{i,j}$ = orthogonal soil springs on pipe, lb/in.
k_v = soil vertical modulus of subgrade reaction, psi
L_1 = length of transverse pipe run, in.
L_2 = length of longitudinal pipe run, in.
L_m = minimum slippage length of pipe, in.
L' = effective slippage length for short pipes, in.
L'' = effective slippage length for long pipes, in.
n = number of modeling elements for pipe springs, dimensionless
N_h = horizontal force factor [8], dimensionless
P = maximum operating pressure in pipe, psi
P_c = confining pressure of backfill on pipe, psi
S_A = allowable expansion stress range, psi
SE = expansion stress, psi
S_h = basic material allowable stress at T degrees fahrenheit, psi
t = pipe wall thickness, in.
T = maximum operating temperature, °F
T_o = ambient temperature of pipe, °F
w = soil density, pfc, pci
W_p = unit weight of pipe and contents, lb/in.
α = coefficient of thermal expansion of pipe, in./in./°F
β = pipe/soil system characteristic [2], in.$^{-1}$
ϵ = pipe unit thermal expansion, in./in.
μ = coefficient of friction, dimensionless
Ω = effective length parameter, in.

[2] Numbers enclosed in brackets [ ] correspond to references cited in VII-7.0.

VII-2.0 LOADS

VII-2.1 Thermal Expansion

Thermal displacements at the elbows, branch connections, and flanges in a buried piping system and the forces and moments resulting from the displacements may be determined by analyzing each buried run of pipe by the method described in this Appendix.

VII-2.1.1 Installations With Continuous Runs. For buried piping installations that contain continuous runs without flexible couplings, the passive restraining effects of soil bearing on the transverse legs at the ends of long runs subject to thermal expansion may be significant and result in high axial forces and elbow or branch connection bending moments.

VII-2.1.2 Installations With Flexible Couplings. For buried piping installations that incorporate flexible couplings into the pipe runs subject to thermal expansion, the bending moments and stresses may be substantially reduced. However, the flexible couplings must be chosen carefully to accommodate the thermal expansion in the pipe, and the friction forces or stiffness in the coupling must be considered.

VII-2.1.3 Installations With Penetration Anchors. For buried piping systems in which the building penetration provides complete restraint to the pipe, it is necessary to calculate the penetration reactions to thermal

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:08 2005

expansion in the initial buried run. If this run incorporates flexible couplings, piping reactions at the penetration resulting from unbalanced forces due to internal pressure must be considered.

VII-2.1.4 Installations With Flexible Penetrations. For buried piping systems in which the building penetrations permit some axial or angular movements, the interaction between the buried run outside the penetration and the point-supported portion of the system inside the building must be considered.

VII-2.2 Pressure

Pressure loads in buried piping are important for two primary reasons.

VII-2.2.1 In pipe runs which incorporate flexible couplings, there is no structural tie between the coupled ends, with the result that internal pressure loads must be reacted externally. External restraint may be provided by thrust blocks, external anchors, soil resistance to elbows or fittings at each end of the pipe run, or by control rods across the coupling. Where one or both of the ends terminate at a penetration or an anchor, or at connected equipment such as a pump or vessel, the pressure forces can be quite high and must be considered in the anchor or equipment design.

VII-2.2.2 For discharge strctures, the reaction forces due to upstream pressure and mass flow momentum in the discharge leg may be high and must be considered in the design of the last elbow or bend before the discharge.

VII-2.3 Earthquake

An earthquake subjects buried piping to axial loads and bending moments from soil strain due to seismic waves, or from ground faulting across the axis of the pipe. The seismic soil strain can be estimated for a design earthquake in a specific geographical region, from which design values for forces and moments in buried piping can be calculated. However, consideration of the magnitude and effects of seismic ground faulting on buried piping is beyond the scope of this Appendix.

VII-3.0 CALCULATIONS

The calculations for stresses in restrained underground piping are carried out in four steps, as follows.

VII-3.1 Assembling the Data

The pipe material and dimensions, soil characteristics, and operating conditions must be established.

VII-3.1.1 Pipe Data

(A) pipe outside diameter D, in.

(B) wall thickness t, in.

(C) length of pipe runs L_1 (transverse) and L_2 (longitudinal), in.

(D) Young's modulus E, psi, (from Appendix C)

(E) pipe depth below grade H, in.

VII-3.1.2 Soil Characteristics

(A) soil density w, pcf (from site tests)

(B) type of backfill

(C) pipe trench width at grade B_d, in.

(D) range of coefficient of friction μ between pipe and backfill

VII-3.1.3 Operating Conditions

(A) maximum operating pressure P, psi

(B) maximum pipe temperature T, °F

(C) ambient pipe temperature T_o, °F

(D) pipe coefficient of thermal expansion α, in./in./°F

VII-3.2 Calculations of Intermediate Parameters

The following parameters must be calculated.

VII-3.2.1 Maximum Relative Strain e at the Pipe/Soil Interface, in./in. For thermal expansion, this is the unit thermal elongation of the unrestrained pipe.

$$\epsilon = \alpha(T - T_o) \quad (1)$$

where

α = coefficient of thermal expansion

$T - T_o$ = difference between operating and installation temperatures

VII-3.2.2 Modulus of Subgrade Reaction k, psi. This is a factor which defines the resistance of the soil or backfill to pipe movement due to the bearing pressure at the pipe/soil interface. Several methods for calculating k have been developed in recent years byAudibert and Nyman, Trautmann and O'Rourke, and others [4, 5, 6, 7, 8]. For example [8], for pipe movement horizontally, the modulus of subgrade k_h may be found by

$$k_h = C_k N_h w D \text{ psi} \quad (2)$$

where

C_k = a dimensionless factor for estimating horizontal stiffness of compacted backfill. C_k may be estimated at 20 for loose soil, 30 for medium soil, and 80 for dense or compacted soil.

w = soil density, lb/in.^{3}

D = pipe outside diameter, in.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:08 2005

N_h = a dimensionless horizontal force factor from Fig. 8 of [8]. For a typical value where the soil internal friction angle is 30 deg, the curve from [8] may be approximated by a straight line defined by

$$N_h = 0.285H/D + 4.3$$

where

H = the depth of pipe below grade at the pipe center line, in.

For pipe movement upward or downward,the procedures recommended in [4] may be applied. Conservatively, the resistance to upward movement may be considered the same as for horizontal movement with additional consideration for the weight of the soil. Resistance to downward movement may conservatively be considered as rigid for most expansion stress analysis.

VII-3.2.3 Unit Friction Force at the Pipe/Soil Interface f

$$f = \mu\,(P_c A_c + W_p) \text{ lb/in.} \quad (3)$$

where

μ = coefficient of friction between pipe and soil
P_c = confining pressure of soil on pipe, psi
A_c = surface area of a pipe segment, in.^{2}
W_p = unit weight of pipe and contents, lb/in.

For piping which is buried within 3 pipe diameters of the surface, confining pressure P_c may be estimated by

$$P_c = wH \text{ lb/in.}^2$$

where

w = the soil density, lb/in.^{3}
H = the depth below grade, in.

For piping which is buried more than 3 pipe diameters below grade, confining pressure P_c is found by using the modified Marston equation [9]:

$$P_c = wC_D B_D \text{ lb/in.}^2$$

where

C_D = a dimensionless parameter obtained from Table VII-3.2.3
B_D = the trench width, with a maximum value of 24 in. plus the pipe diameter

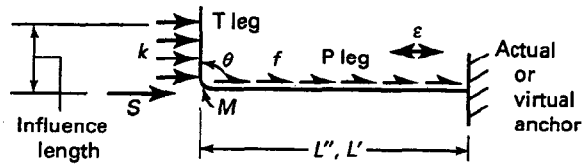

FIG. VII-3.3.2-1 ELEMENT CATEGORY A, ELBOW OR BEND

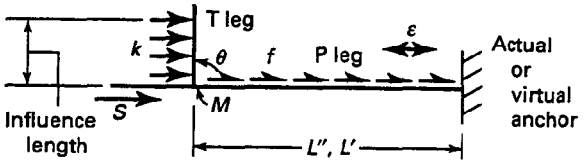

FIG. VII-3.3.2-2 ELEMENT CATEGORY B, BRANCH PIPE JOINING THE P LEG

$$F_{max} = fL_m = \epsilon AE \text{ lb} \quad (6)$$

VII-3.3 Classification of the Pipe Runs

VII-3.3.1 Purpose. The classification and subclassification of the buried pipe elements is used in choosing the proper equation for effective slippage length L' or L'' which is then used in calculating piping forces and stresses. The pipe segment identified by the dimension L' or L'' always begins at either an elbow, bend, tee, or branch connection and terminates at the point (described below as the "virtual anchor") at which there is no slippage or relative movement at the pipe/soil interface.

VII-3.3.2 Classification of the Pipe Elements. It is in the bends, elbows, and branch connections that the highest stresses are found in buried piping subject to thermal expansion of the pipe. These stresses are due to the soil forces that bear against the transverse run (the run running perpendicular or at some angle to the direction of the pipe expansion). The stresses are proportional to the amount of soil deformation at the elbow or branch connection.

Piping elements are divided into three major categories depending upon what type of transverse element is being analyzed, as follows:

Category A: elbow or bend (see Fig. VII-3.3.2-1)

Category B: branch pipe joining the longitudinal run (see Fig. VII-3.3.2-2)

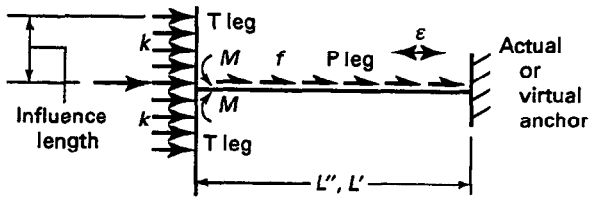

FIG. VII-3.3.2-3 ELEMENT CATEGORY C, TEE ON END OF P LEG

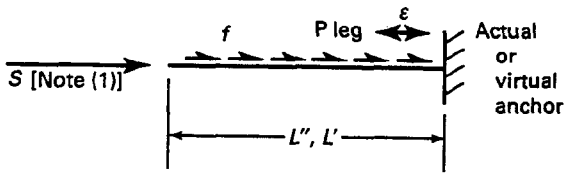

NOTE:
(1) Expansion joint pressure load plus sliding or convolution loads.

FIG. VII-3.3.2-4 ELEMENT CATEGORY D, STRAIGHT PIPE

Category C: longitudinal run ending in a tee (see Fig. VII-3.3.2-3)

Category D: straight pipe, no branch or transverse run (see Fig. VII-3.3.2-4)

Categories A, B, and C are further divided into three subcategories depending on the configuration of the pipe run at the end opposite that being analyzed. The piping elements are classified as follows:

A1, B1, C1: other end free or terminating in a flexible coupling or joint

A2, B2, C2: other end contains an elbow or tee

A3, B3, C3: other end is anchored

Category D elements include straight runs between an anchor (either actual or virtual) and a free end or a pipe section that is connected to an expansion joint.

The elements are further broken down into subtypes depending upon whether the longitudinal run (the pipe or P leg) and the transverse run (called the T leg) are long or short with respect to certain criteria. The transverse or T leg is the run against which the soil bears, producing an in-plane bending moment in elbow, branch, or tee. (Category D elements have no transverse leg.)

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:09 2005

The strict criterion for a long or short transverse leg is whether the length of the transverse run L_1 is longer or shorter than $3\pi/4\beta$, the length at which the hyperbolic functions in Hetenyi's equations [2] approach unit. The critical value for L_1 is often called the "influence" length, or that portion of transverse or T run which is deflected or "influenced" by seismic soil strain or pipe thermal expansion along the axis of the longitudinal or P run. In practice, a critical influence length L_1 of $1/\beta$ to $1.2/\beta$ may often be used, since there is very little deformation or load in that portion of the transverse run which exceeds this length. This implies that the vast majority of the bearing load on the transverse or T leg occurs in the first several feet of the pipe at the bend or branch. In summary, a transverse pipe is "long" if

$$L_1 \geq 3\pi/4\beta \text{ (conservative)}$$

or

$$L_1 \geq 1/\beta \text{ to } 1.2/\beta \text{ (usually acceptable)}$$

The criterion for a short or long P leg is whether or not its length L_2 is sufficiently long to experience the maximum force that can develop at the friction interface. For full maximum friction force ($F_{max} = \epsilon AE$) to occur in a straight pipe axially free at each end, its length L_2 would have to equal or exceed $2L_m$ with L_m calculated by Eq. (5). If one end terminates in an elbow or a tee, with the other end remaining axially unrestrained, the total length L_2 necessary for full friction to develop is $L'' + L_m$; the friction force over L_m is equal to the soil bearing force S plus the friction force acting on the length L' or L'', which is called the effective slippage length. The effective slippage length is the maximum length along which slippage occurs at the pipe/soil interface of a pipe with a transverse leg or branch. The effective slippage length L'' for long pipes with long transverse legs is calculated by

$$L'' = \Omega[(1 + 2F_{max}/f\Omega)^{1/2} - 1] \text{ in.} \quad (7)$$

where

$\Omega = AE\beta/k$

and F_{max} is calculated by Eq. (6).

Equation (7) applies to bends, tees, and branches. Although Eq. (7) was developed for the case where $L_2 = L'' + L_m$, it applies also for any case where $L_2 > L'' + L_m$, since the length of the region where there is zero slippage at the friction interface is immaterial [1]. Using L'' as calculated by Eq. (7), it can now be established that a P leg is classified long if it meets these criteria:

(A) For Types A1, B1, C1, $L_2 \geq L_m + L''$;

(B) For Types A2, B2, C2, $L_2 \geq 2L''$;

(C) For Types A3, B3, C3, D, $L_2 \geq L''$.

That point which is located a distance L' or L'' from the bend, branch, or tee, is called the virtual anchor, since it acts as if it were a three-axis restraint on the pipe.

VII-3.3.4 Locating the Virtual Anchor. Calculation of the forces and moments in buried piping at the changes in direction requires that the location of the virtual anchor (the effective slippage length L' away from the bend or branch element) in the P run and deformation δ of the soil at the buried element be established. For elements of all types with long P legs, L'' may be calculated by Eq. (7).

For Types A1, B1, and C1 elements (with one end of the P leg free or unrestrained axially) with "short" P legs L' must be found by a less direct method as follows [1]:

$$L' = [-b + (b^2 - 4ac)^{1/2}]/2a \text{ in.} \quad (8)$$

where

$a = 3f/(2AE)$

$b = \epsilon - fL_2/(AE) + 2f\beta/k$

$c = -f\beta L_2/k$

However, the most highly stressed runs in a buried piping system typically are restrained at both ends, either by a combination of transverse runs or a transverse and an anchor (either real or virtual).

For Types A2, B2, and C2 elements with short P legs, L' is expressed by

$$L' = L_2/2 \text{ in.} \quad (9)$$

For Types A3, B3, C3, and D elements with short P legs, L' is expressed by

$$L' = L_2 \text{ in.} \quad (10)$$

VII-4.0 COMPUTER MODELING OF BURIED PIPING

VII-4.1 Determination of Stresses

With f, k, and L' or L'' established, the stresses in a buried pipe due to thermal expansion can be determined with a general purpose pipe stress computer program. A buried piping system can be modeled

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:10 2005

with a typical mainframe or microcomputer pipe stress program by breaking the buried portions into elements of convenient length and then imposing a transverse spring at the center of each element to simulate the passive resistance of the soil. The entire pipe can be divided into spring-restrained elements in this manner; however, the only regions of the pipe that really need to be modeled in this manner are the lengths entering and leaving elbows or tees. The analyst should refer to the program users' manual for guidance in modeling soil springs.

All pipe stress computer programs with buried piping analysis options require that the following factors be calculated or estimated:

(A) Location of the virtual anchor (dimension L' or L'')

(B) Soil spring rate $k_{i,j}$, which is a function of the modulus of subgrade reaction k.

(C) Influence length, also a function of k.

Some programs ignore the friction at the pipe/soil interface; this is conservative for calculating bending stresses on the buried elbows and branch connections, but may be unconservative for calculating anchor reactions.

VII-4.2 Determination of Element Lengths

The element lengths and transverse soil spring rates for each element are calculated by the following procedure:

VII-4.2.1 Establish the element length dL and the number n of elements, as follows:

(A) Set the element length to be equal to between 2 and 3 pipe diameters. For example, dL for a NPS 6 may be set at either 1 ft or 2 ft, whichever is more convenient for the analyst.

(B) Establish the number n of elements by:

$$n = (3\pi/4\beta)/dL \tag{11}$$

This gives the number of elements, each being dL inches in length, to which springs are to be applied in the computer model. The number n of elements is always rounded up to an integer.

VII-4.2.2 Calculate the lateral spring rate $k_{i,j}$ to be applied at the center of each element.

$$k_{i,j} = kdL \text{ lb/in.} \tag{12}$$

where

k = the modulus of subgrade reaction calculated from Eq. (2).

VII-4.2.3 Calculate the equivalent axial load necessary to simulate friction resistance to expansion. The friction resistance at the pipe/soil interface can be simulated in the computer model by imposing a single force F_f in a direction opposite that of the thermal growth.

$$F_f = fL'/2 \text{ or } fL''/2 \text{ lb} \tag{13}$$

VII-4.2.4 Incorporate the springs and the friction force in the model. The mutually orthogonal springs $k_{i,j}$ are applied to the center of each element, perpendicular to the pipe axis. Shorter elements, with proportionally smaller values for the springs on these elements, may be necessary in order to model the soil restraint at elbows and bends. The friction force F_f for each expanding leg is imposed at or near the elbow tangent node, opposite to the direction of expansion.

VII-4.3 Determination of Soil Parameters

Soil parameters are difficult to establish accurately due to variations in backfill materials and degree of compaction. Consequently, values for elemental spring constants on buried pipe runs can only be considered as rational approximations. Stiffer springs can result in higher elbow stresses and lower bending stresses at nearby anchors, while softer springs can have the opposite effects. Backfill is not elastic, testing has shown that soil is stiffest for very small pipe movements, but becomes less stiff as the pipe movements increase. References [4], [7], and [8] discuss soil stiffness and recommend procedures for estimating values for k which are consistent with the type of soil and the amount of pipe movement expected. The analyst should consult the project geotechnical engineer for assistance in resolving any uncertainties in establishing soils parameters, such as the modulus of subgrade reaction k, confining pressure p_c, and coefficient of friction μ.

VII-4.4 Pipe With Expansion Joints

An expansion joint must be considered as a relatively free end in calculating stresses on buried elbows and loads on anchors. Since incorporation of expansion joints or flexible couplings introduces a structural discontinuity in the pipe, the effects of the unbalanced pressure load and the axial joint friction or stiffness must be superimposed on the thermal expansion effects

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:10 2005

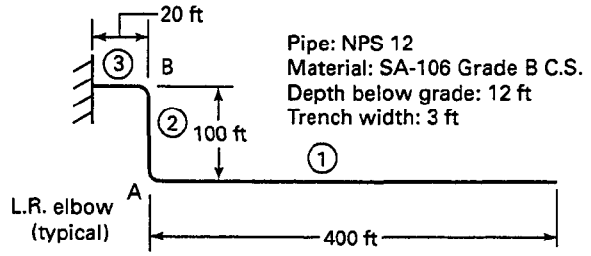

FIG. VII-5.0 PLAN OF EXAMPLE BURIED PIPE

in order to determine the maximum pipe stresses and anchor loads.

VII-4.5 Pipe Stresses at Building Penetrations

Stresses at building penetrations can be calculated easily after the reactions due to thermal expansion in the buried piping have been determined. If the penetration is an anchor, then the stress due to the axial force F_{max} and the lateral bending moment M can be found by

$$S_E = F_{max}/A + M/Z \text{ psi} \quad (14)$$

If the penetration is not an anchor, but is instead a simple support with a flexible water seal, it is necessary to determine the stiffness affects of the water seal material in order to calculate the stress in the pipe at the penetration. Differential movement due to building or trench settlement can generate high theoretical stresses at piping penetrations to buildings. Calculation of such stresses is beyond the scope of this Appendix.

VII-5.0 ALLOWABLE STRESS IN BURIED PIPE

Buried piping under axial stress can theoretically fail in one of two ways: either by column buckling (pipe pops out of the ground at mid-span) or local failure by crippling or tensile failure (much more serious than column buckling). Since buried piping stresses are secondary in nature, and since the piping is continuously supported and restrained (see Fig. VII-5.0), higher total stresses may be permitted as follows:

$$S_C \le S_A + S_h \quad (15)$$

where S_A and S_h are as defined in para. 102.3.2.

VII-6.0 EXAMPLE CALCULATIONS

VII-6.1 Assemble the Data

VII-6.1.1 Pipe Data

(A) diameter D = 12.75 in.
(B) wall thickness = 0.375 in.
(C) length of runs:
(C.1) Run 1: L_1 = 100 ft, L_2 = 400 ft
(C.2) Run 2: L_1 = 20 ft, L_2 = 100 ft
(C.3) Run 3: L_1 = 100 ft, L_2 = 20 ft
(D) Young's modulus $E = 27.9 \times 10^6$ psi
(E) moment of inertia I = 279.3 in^4
(F) cross section metal area A = 14.57 in.^{2}

VII-6.1.2 Soil Characteristics

(A) soil density w = 130 lb/ft^3
(B) pipe depth below grade H = 12 ft (144 in.)
(C) type of backfill: dense sand
(D) trench width B_d = 3 ft (36 in.)
(E) coefficient of friction μ = 0.3 min. to 0.5 max. (estimated)
(F) horizontal soil stiffness factor C_k = 80

VII-6.1.3 Operating Conditions

(A) pressure P = 100 psig
(B) temperature = 140°F
(C) ambient temperature = 70°F

VII-6.2 Calculate the Intermediate Parameters

VII-6.2.1 Relative Strain at the Pipe/Soil Interface. Thermal expansion for SA-106 Grade B carbon steel pipe from 70°F to 140°F is 0.0053 in./ft. Therefore,

$$\epsilon = (0.0053 \text{ in./ft})/(12 \text{ in./ft})$$
$$= 0.000424 \text{ in./in.}$$

VII-6.2.2 Modulus of Subgrade Reaction k [8]. Since the expansion is in the horizontal plane, use k_h from Eq. (2):

$$k_h = C_k N_h w D \quad (2)$$

$$C_k = 80$$

$$N_h = 0.285\, H/D + 4.3$$

$$= 0.285 \text{ (12 ft)(12 in./ft)/12.75 in.} + 4.3$$

$$= 7.519$$

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:10 2005

$$w = 130 \text{ pcf}/(1728 \text{ in.}^3/\text{ft}^3)$$

$$= 0.0752 \text{ lb/in.}^3$$

$$D = 12.75 \text{ in.}$$

$$k_h = (80)(7.519)(0.0752)(12.75) = 577 \text{ lb/in.}^2$$

VII-6.2.3 Friction Forces per Unit Length Acting at the Pipe/Soil Interface

$$f = \mu(P_c A_c + W_p) \quad (3)$$

Since the pipe lies more than 3 diameters below grade, the modified Marston equation from [1] is used to determine the confining pressure P_c of soil on the pipe.

$$P_c = wC_D B_d$$

$$C_D = 2.22 \text{ for } H/B_d = 12 \text{ ft.}/3 \text{ ft.}$$

$$= 4 \text{ (see Table VII-3.2.3 for sand)}$$

$$P_c = (130 \text{ pcf})(2.22)(3 \text{ ft.})/(144 \text{ in.}^2/\text{ft}^2)$$

$$= 6.01 \text{ psi}$$

$$A_c = D(1 \text{ in.}) = (12.75 \text{ in.})(1 \text{ in.})$$

$$= 40.05 \text{ in.}^2/\text{in. of length}$$

$W_p = 8.21$ lb/in. for water-filled carbon steel pipe

Maximum value of friction force per unit length f_{max}:

$$f_{max} = 0.5 [(6.01 \text{ psi})(40.05 \text{ in.}^2/\text{in.}) + 8.21 \text{ lb/in.}] \quad (3)$$

$$= 124.5 \text{ lb/in.}$$

Minimum value of friction force per unit length f_{min}:

$$f_{min} = 0.3 [(6.01)(40.05) + 8.21] \quad (3)$$

$$= 74.7 \text{ lb/in.}$$

VII-6.2.4 Pipe/Soil System Characteristic β [2]

$$\beta = [k_h/(4EI)]^{1/4} \quad (4)$$

$$= [577 \text{ psi}/4(27.9 \times 10^6 \text{ psi})(279.3 \text{ in.}^4)]^{1/4}$$

$$= 0.01166 \text{ in.}^{-1}$$

VII-6.2.5 Minimum Slippage Length L_m

$$L_m = \epsilon AE/f_{min} \quad (5)$$

$$= (0.000424 \text{ in./in.})(14.57 \text{ in.}^2)(27.9 \times 10^6 \text{ psi})$$

$$/74.7 \text{ lb/in.}$$

$$= 2307 \text{ in. or } 192 \text{ ft } 4 \text{ in.}$$

VII-6.2.6 Maximum Axial Force F_{max} Corresponding to L_m

$$F_{max} = \epsilon AE = (0.000424)(14.57)(27.9 \times 10^6) \quad (6)$$

$$= 172{,}357 \text{ lb}$$

VII-6.3 Classification of Runs

Classify the pipe runs in accordance with the models given in Table VII-6.3 and calculate the effective slippage length L' or L'' for each run.

VII-6.3.1 Run 1 is a Category A1 (elbow on one end, the other end free). Check to see if the transverse leg L_1 is long or short.

$$L_1 = 1200 \text{ in.}$$

$$3\pi/(4)(0.01166 \text{ in.}^{-1}) = 202 \text{ in.}$$

Since 1200 in. > 202 in., L_1 is long. Check to see if the longitudinal leg L_2 is long or short, that is, longer or shorter than $L_m + L''$. Using Eq. (7) to calculate L'',

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:11 2005

TABLE VII-6.3
EQUATIONS FOR CALCULATING EFFECTIVE LENGTH L' OR L''

Element Category	Equations for L' or L''	
	Short P Leg L'	Long P Leg L''
A1, B1, C1	If $L_2 < L_m + L''$, $L' = [-b + (b^2 - 4ac)^{1/2}]/2a$ (8) where $a = 3fI/(2AE)$, $b = \epsilon - fL_2/(AE) + 2f\beta/k$, $c = -f\beta L_2/k$	If $L_2 \geq L_m + L''$, $L'' = \Omega[(1 + 2F_{max}/f_{min}\Omega)^{1/2} - 1]$ (7)
A2, B2, C2	If $L_2 < 2L''$, $L' = L_2/2$ (9)	If $L_2 \geq 2L''$, $L'' = \Omega[(1 + 2F_{max}/f_{min}\Omega)^{1/2} - 1]$ (7)
A3, B3, C3	If $L_2 < L''$, $L' = L_2$ (10)	If $L_2 \geq L''$, $L'' = \Omega[(1 + 2F_{max}/f_{min}\Omega)^{1/2} - 1]$ (7)
D	If $L_2 < L_m$, $L' = L_2$ (10)	If $L_2 \geq L_m$, $L'' = L_m = \epsilon AE/f$ (5)

$$L'' = \Omega[(1 + 2F_{max}/f_{min}\Omega)^{1/2} - 1] \quad (7)$$

$$\Omega = AE\beta/k = (14.57 \text{ in.}^2)(27.9 \times 10^6 \text{ psi}) \times (0.01166 \text{ in.}^{-1})/577 \text{ psi} = 8214 \text{ in.}$$

$$L'' = 8214\{[1 + 2 \times 172{,}357/(74.7 \times 8214)]^{1/2} - 1\}$$

$$= 2051 \text{ in.}$$

$$L_m + L'' = 2307 + 2051 = 4358 \text{ in.}$$

Since L_2 = 400 ft or 4800 in., then since 4800 > 4358, the pipe run length L_2 is long, and Run 1 can be fully classified as Category A1 (long transverse, long pipe).

NOTE: If $L_m + L''$ would have exceeded L_2, then L' would be recalculated using Eq. (8), the correct equation for a short pipe.

VII-6.3.2 Run 2 is a Category A2 (elbow on each end). Check to see if the legs L_1 and L_2 are long or short.

Since $L_1 > 3\pi/4\beta$ (240 in. > 202 in.) and since $L_2 < 2L''$ [1200 in. < 2(2051 in.)], then Run 2 can be fully classified as a Category A2 (long transverse, short pipe). Then

$$L' = L_2/2 = (1200 \text{ in.})/2 = 600 \text{ in.}$$

VII-6.3.3 Run 3 is a Category A3 (anchor on one end, elbow on the other). Check to see if the legs L_1 and L_2 are long or short.

Since $L_1 > 3\pi/4\beta$ (1200 in. > 202 in.) and $L_2 < L''$ (240 in. < 2051 in.), then Run 3 can be fully classified as a Category A3 (long transverse, short pipe). Then

$$L' = L_2 = 240 \text{ in.}$$

NOTE: In order to fully qualify a buried piping system, it may also be necessary to include stresses due to weight of overburden (backfill) and vehicular loads [5, 6].

VII-6.4 Computer Modeling

Calculate the soil springs and friction force for use in a computer model of the buried pipe.

VII-6.4.1 Element Length. Set the element length to be ≈ 3 pipe diameters. dL = 36 in.

VII-6.4.2 Number of Elements. Only the soil within a length $3\pi/4\beta$ from the elbow will be subject to bearing force from the pipe. For the example system, $3\pi/4\beta$ = 202 in. Therefore, the number of elements needed is found by

$$n = (3\pi/4\beta)/dL = 202/36 = 5.61 \quad (11)$$

Therefore, use 6 elements, each 36 in. long.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:11 2005

VII-6.4.3 Spring Rate k_{ij}. The spring rate to be applied to each element is found by

$$k_{i,j} = kdL \tag{12}$$

where k is from Eq. (2)

$$k_{i,j} = (577 \text{ psi})(36 \text{ in.}) = 20{,}772 \text{ lb/in.}$$

This is the theoretical spring rate to be imposed at the center of each element and normal to the surface of the pipe, with k_i in the plane of the expansion, and k_j perpendicular to the plane of expansion.

VII-6.4.4 Friction Force F_f. The friction forces to be applied at the elbow tangent points in Runs 1 and 2 are calculated as follows:

Parallel to Run 1:

$$F_f = fL''/2 \tag{13}$$

where

$f = f_{\min} = 74.7$ lb/in.
$L'' = 2051$ in.

$$F_f = (74.7 \text{ lb/in.})(2051 \text{ in.})/2 = 76{,}605 \text{ lb}$$

Parallel to Run 2:

$$F_f = (74.7 \text{ lb/in.})(600 \text{ in.})/2 = 22{,}410 \text{ lb} \tag{13}$$

The friction force to be applied at the elbow tangent point in Run 3 is calculated as follows:

Parallel to Run 3:

$$F_f = (74.7 \text{ lb/in.})(240 \text{ in.})/2 = 8964 \text{ lb} \tag{13}$$

The computer model then appears as is shown in Fig. VII-6.4.4.

VII-6.5 Results of Analysis

Computer analysis of the model shown in Fig. VII-6.4.4 gives combined stress S_C at various locations in the buried pipe as follows:

Location	S_C, psi
Virtual anchor	7,036
Elbow A	26,865
Elbow B	9,818
Penetration anchor	2,200

NOTE: S_C for this example includes longitudinal pressure stress, intensified bending stresses, and direct stresses due to axial loads from friction and soil bearing loads. It does not include weight of backfill or live loads.

The allowable stress as given by Eq. (15) is $S_A + S_h$, which for SA-106 Grade B steel pipe is 22,500 psi + 15,000 psi = 37,500 psi. Therefore, since the maximum S_C of 26,865 psi < 37,500 psi, the Code conditions are met.

VII-6.6 Anchor Load Example

If Element 1 were simply a straight pipe anchored at one end with the other end terminating in an expansion joint (see Fig. VII-6.6), the load on the anchor is found as follows.

(A) Calculate the maximum friction force acting along the friction interface.

$$F_f = F_{\max} = \epsilon AE \tag{6}$$

$$F_{\max} = \epsilon AE = (0.000424)(14.57)(27.9 \times 10^6) \tag{6}$$

$$= 172{,}357 \text{ lb}$$

(B) Calculate the load S at the expansion joint.

$$S = F_j + S_p$$

where

F_j = expansion joint friction force
= 9000 lb (from vendor data)
S_p = pressure force
= PA_s
where
P = design pressure
= 100 psig
A_s = effective cross-sectional area
= $\pi D^2/4$
= $\pi\ (12.75^2)/4$
= 127.6 in.^{2}

$$S_p = (100)(127.6) = 12{,}760 \text{ lb}$$

$$S = 9{,}000 + 12{,}760 = 21{,}760 \text{ lb}$$

(C) The total axial load F_a at the anchor then becomes

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:12 2005

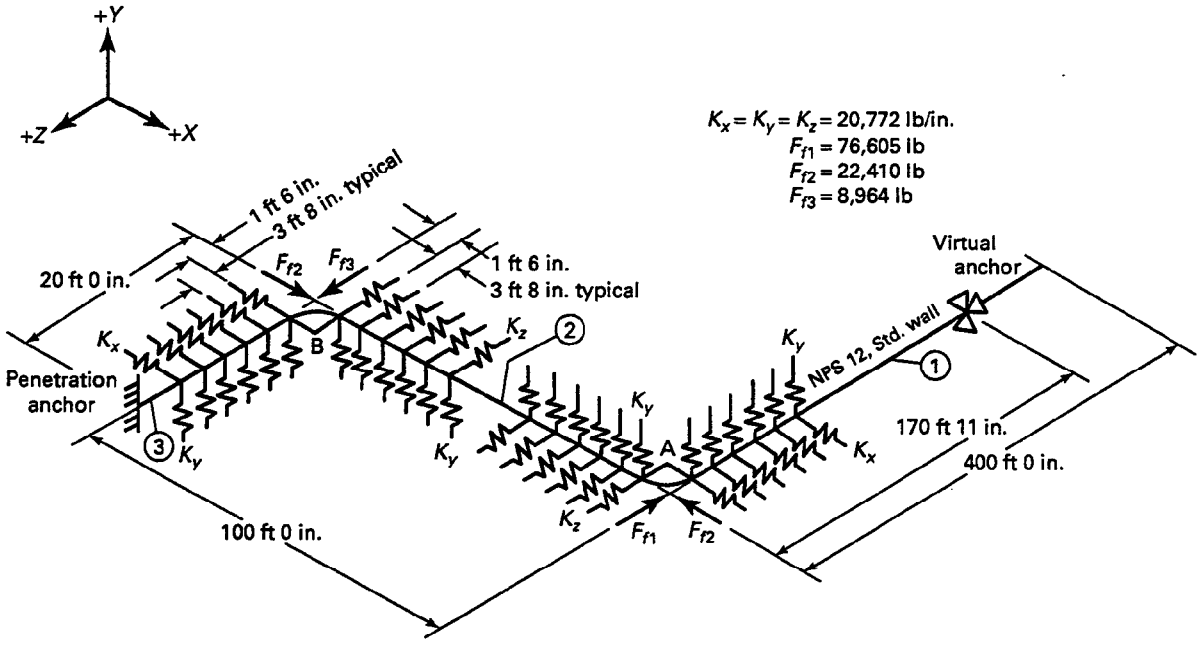

FIG. VII-6.4.4 COMPUTER MODEL OF EXAMPLE PIPE

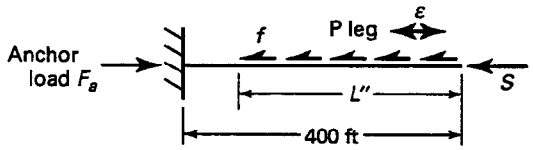

FIG. VII-6.6 EXAMPLE PLAN OF ELEMENT 1 AS A CATEGORY D ELEMENT

$$F_a = 172{,}357 + 21{,}760 = 194{,}117 \text{ lb}$$

If anchor loads must be limited, then the expansion joint should be located closer to the anchor in order to reduce the force due to friction at the pipe/soil interface.

ASME B31.1

INTERPRETATIONS VOL. 35

Replies to Technical Inquiries
January 1, 2000, Through June 30, 2000

It has been agreed to publish intepretations issued by the B31 Committee concerning B31.1 as part of the update service to the Code. The interpretations have been asssigned numbers in chronological order. Each interpretation applies either to the latest Edition or Addenda at the time of issuance of the interpretation or the Edition or Addenda stated in the reply. Subsequent revisions to the Code may have superseded the reply.

The replies are taken verbatim from the original letters, except for a few typographical and editorial corrections made for the purpose of improved clarity. In some instances, a review of the interpretation revealed a need for corrections of a technical nature. In these cases, a revised reply bearing the original interpretation number with the suffix R is presented. In the case where an interpretation is corrected by Errata, the original interpretation number with the suffix E is used.

ASME procedures provide for reconsideration of these interpretations when or if additional information is available which the inquirer believes might affect the interpretation. Further, persons aggrieved by an interpretation may appeal to the cognizant ASME committee or subcommittee. As stated in the Statement of Policy in the Code documents, ASME does not "approve," "certify," "rate," or "endorse" any item, construction, proprietary device, or activity.

Interpretations Nos. 2 through 7 were included with the update service to the 1983 Edition and Interpretations Nos. 8 through 13 were included with the update service to the 1986 Edition. Interpretations Nos. 14 through 19 were included with the update service to the 1989 Edition. Interpretations Nos. 20 through 25 were included with the update service to the 1992 Edition. Interpretations Nos. 26 through 30 were included with the update service to the 1995 Edition. Interpretations Nos. 31 through 34 were included with the update service to the 1998 Edition. For the 2001 Edition, interpretations will be issued as necessary up to twice a year until the publication of the 2004 Edition.

B31.1

Subject	Interpretation	File No.
Para. 124, ASTM A 671, CC70 Class 22 Pipe Material Application	35-3	B31-99-036
Para. 136.4.3(B), Magnetic Particle Examination	35-2	B31-99-015
Welding of Butt Welded Fittings	35-1	B31-97-055

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:16 2005

Interpretation: 35-1

Subject: B31.1, Welding of Butt Welded Fittings

Date Issued: April 24, 2000

File: B31-97-055

Question: Does ASME B31.1 prohibit butt welding fittings to be welded directly to fillet welding fittings (e.g., a butt welding elbow to a slip on flange) using fillet welds?

Reply: No, if neither fitting is modified to fabricate the assembly. However, if one or both of the fittings are modified, the fitting or fittings may no longer be considered to be standard fittings and shall be qualified in accordance with para. 104.7.2. The requirements of para. 104.8 shall be met considering the effect of any modifications

Interpretation: 35-2

Subject: B31.1, Para. 136.4.3(B), Magnetic Particle Examination

Date Issued: April 24, 2000

File: B31-99-015

Question: When using MT, what size of indication is considered relevant?

Reply: All MT indications that do not meet the acceptance criteria of para. 136.4.3(B) are considered relevant.

Interpretation: 35-3

Subject: B31.1, Para. 124, ASTM A 671, CC70 Class 22 Pipe Material Application

Date Issued: June 9, 2000

File: B31-99-036

Question: Does ASME B31.1 prohibit the use of ASTM A 671, CC70, Class 22, Specification for Electric-Fusion Welded Steel Pipe for Atmospheric and Lower Temperatures, for service at temperatures for which allowable stress values are listed in Appendix A?

Reply: No. Refer to para. 124.9.

B31.1

Subject	Interpretation	File No.
Para. 102.3.1(C), Allowable Stresses	36-2	B31-99-016
Para. 104.3.1(E), Branch Connections	36-1	B31-99-014

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:17 2005

Interpretation: 36-1

Subject: B31.1, Para. 104.3.1(E), Branch Connections

Date Issued: October 3, 2000

File: B31-99-014

Question (1): Per 1998 Edition of ASME B31.1, Power Piping, is Formula (3) or (3A) given in para. 104.1.2 to be used to determine t_{mh} when designing a branch connection for external pressure?

Reply (1): Neither; t_{mh} shall be determined in accordance with para. 104.1.3, provided D_{oh}, D_{ob}, and t_r, if reinforcement is required, are reduced to compensate for external corrosion.

Question (2): Is t_{mh} then used in the formula in paragraph 104.3.1(E) to determine the required reinforcement area?

Reply (2): Yes.

Interpretation: 36-2

Subject: B31.1, Para. 102.3.1(C), Allowable Stresses

Date Issued: October 3, 2000

File: B31-99-016

Question: May the allowable stresses listed in Tables 1A and 1B of Section II, Part D of the ASME Boiler and Pressure Vessel Code, for usage by Section I of that Code, be used in B31.1 designs, provided that the material has been approved by B31.1?

Reply: No. B31.1 does not permit the use of Section II values.

B31.1 — Cases No. 27

A Case is the official method of handling a reply to an inquiry when study indicates that the Code wording needs clarification, or when the reply modifies the existing requirements of the Code, or grants permission to use new materials or alternative constructions.

ASME has agreed to publish Cases issued by the B31 Committee concerning B31.1 as part of the update service to B31.1. The text of proposed new and revised Cases and reaffirmations of current Cases appear in *Mechanical Engineering* for public review. A notice also appears in *Mechanical Engineering* when new and revised Cases are approved. New and revised Cases, as well as announcements of reaffirmed Cases and annulments, then appear in the next update. All Cases currently in effect at the time of publication of the 1989 Edition of the Code were included in the update that immediately followed, Interpretations No. 14 and Cases No. 9. As of the 1992 and later Editions, all Cases currently in effect at the time of publication of an Edition are included with it as an update.

This update, Cases No. 27, which is included after the last page of the 2001 Edition and the Interpretations No. 35 that follow, contains the following Cases.

145	153	163	165	173
146-1	162	164	170	

Cases 147, 151, 154, 159, 161, and 168, which were included in the first update to the 1998 Edition (Cases No. 25), were allowed to expire. Case 169, which was included in the second update (Cases No. 26), was also allowed to expire.

The page numbers for the Cases supplements included with updates to the 2001 Edition start with C-1 and will continue consecutively through the last update to this Edition. The Cases affected by this supplement are as follows:

Page	*Location*	*Change*
C-1	Case 145	(1) Reaffirmed: July 2000 (2) New expiration date: July 31, 2003
C-2, C-3	Case 146-1	(1) Reaffirmed: March 2001 (2) New expiration date: March 31, 2004
C-8, C-9	Case 163	(1) Reaffirmed: July 2000 (2) New expiration date: July 31, 2003
C-10	Case 164	(1) Reaffirmed: September 2000 (2) New expiration date: September 30, 2003
C-11	Case 165	(1) Reaffirmed: July 2001 (2) New expiration date: July 31, 2004
C-14	Case 173	Added

B31 CASE 145
Nickel–Molybdenum–Chromium Alloys (UNS N10276), ANSI/ASME B31.1 Construction

Approval Date: August 1985
Reaffirmation Date: July 2000

This case shall expire on July 31, 2003, unless previously annulled or reaffirmed

Inquiry: May nickel–molybdenum–chromium alloy (UNS N10276) fittings, rod, plate, and strip, seamless and welded pipe and tube conforming to ASTM B 366, B 574, B 575, B 619, B 622, and B 626 be used for ANSI/ASME B31.1 construction?

Reply: It is the opinion of the Committee that nickel–molybdenum–chromium alloy (UNS N10276) may be used in ANSI/ASME B31.1 construction provided:

(1) the maximum allowable stress values for the material shall be those given in Table I. For welded components, these values shall be multiplied by a factor of 0.85.

(2) welded fabrication shall conform to the applicable requirements of B31.1:

(a) Welding Procedure and Performance Qualifications shall be conducted in accordance with Section IX, ASME Boiler and Pressure Vessel Code.

(b) Welding shall be done by any welding process capable of meeting the requirements.

(c) All filler metal, including consumable insert material, shall comply with the requirements of Section IX.

(d) When welding repair of a defect is required, it shall be in accordance with ANSI/ASME B31.1, para. 127.4.11. When a defect is removed but welding repair is unnecessary, the surface shall be contoured to eliminate any sharp notches or corners. The contoured surface shall be reinspected by the same means originally used for locating the defect to assure it has been completely removed.

(e) Heat treatment after fabrication or forming is neither required nor prohibited.

(3) this Case number shall be identical in the Data Report.

TABLE I

For Metal Temperature Not Exceeding, °F	Maximum Allowable Stress, ksi[1]	Maximum Allowable Stress, ksi
100	25.0	25.0
200	25.0	25.0
300	25.0	23.0
400	24.3	21.2
500	23.9	20.0
600	23.5	18.8
650	23.3	18.3
700	23.1	17.8
750	22.9	17.4
800	22.8	17.1
850	22.6	16.8
900	22.3	16.6
950	22.1	16.5
1000	21.8	16.5

NOTE:
(1) Due to the relatively low yield strength of these materials, these higher stress values were established at temperatures where the short time tensile properties govern to permit the use of these alloys where slightly greater deformation is acceptable. These higher stress values exceed 67% but do not exceed 90% of the yield strength at temperature. Use of these stresses may result in dimensional changes due to permanent strain. These stress values are not recommended for the flanges of the gasketed joints or other applications where slight amounts of distortion can cause leakage or malfunction.

B31 CASE 146-1
Nickel–Chromium–Molybdenum–Columbium Alloy (UNS N06625) in ASME B31.1 Construction

Approval Date: March 1989
Reaffirmation Date: March 2001

This case shall expire on March 31, 2004, unless previously annulled or reaffirmed

Inquiry: May nickel–chromium–molybdenum–columbium alloy (UNS N06625) conforming to the specifications listed in Table I be used for construction of ASME B31.1 Power Piping systems?

Reply: It is the opinion of the Committee that nickel–chromium–molybdenum–columbium alloy (UNS N06625) conforming to the product specifications shown in Table I may be used in the construction of power piping complying with the rules of ASME B31.1 provided the following additionl requirements are met.

(1) THESE MATERIALS SHALL NOT BE USED FOR BOILER EXTERNAL PIPING. See para. 100.1.2(A).

(2) The allowable stress values shall be those listed in Table II.

(3) All longitudinal welds in any of the materials listed in Table I shall be completely examined by radiography. Radiographic examination shall be in accordance with the requirements of the ASME Boiler and Pressure Vessel Code, Section VIII, latest edition, para. UW-51.

(4) The welding procedure qualification and performance qualifications shall be conducted in accordance with ASME Boiler and Pressure Vessel Code, Section IX. For qualifying welding procedures, the material is P-No. 43.

(5) Postweld heat treatment of this material is neither required nor prohibited. However, no postweld heat treatment shall be performed except by agreement between the owner and the manufacturer, installer, or erector. The temperature, time, and method of heat treatment shall be covered by the agreement.

(6) Longitudinally seam welded pipe, with or without filler metal added, is permitted. Longitudinally seam welded pipe shall be fabricated from plate meeting the requirements of ASTM B 443. All seam welded pipe shall comply with the following requirements.

(a) The welds shall be made by an electric arc process.

(b) The joints shall be full penetration double-welded or single-welded butt joints employing fusion welding processes as defined under para. 100.2 Definitions of ASME B31.1. Where backing rings or strips are used, the ring or strip material shall be of the same P-Number as the plate being joined. Backing rings or strips shall be completely removed after welding prior to radiography, and the exposed weld surface shall be examined visually for conformance to the requirement of the following paragraph. Welds made by procedures using backing rings which remain in place are prohibited.

(c) The weld surface on the outside diameter side of the pipe shall be flush with the base plate or shall have a reasonably uniform crown in accordance with Table 127.4.2 of ASME B31.1. The weld reinforcement on the inside diameter side of the pipe may be removed at the manufacturer's option or by agreement between the manufacturer and purchaser. The contour of the reinforcement shall be reasonably smooth and free of irregularities. The deposited metal shall be fused uniformly into the plate surface. No concavity of contour is permitted.

(d) Weld defects shall be repaired by removal to sound metal and rewelding. Subsequent heat treatment and inspection shall be as required on the original welds.

(e) When heat treatment is required, such heat treatment shall be done in accordance with para. 5, after all welding.

(f) The requirements of ASTM A 530 for welded pipe shall be met. Variations in wall thickness and length for longitudinally seam welded pipe with filler metal added shall be the same as required in ASTM A 530 for seamless or longitudinally seam welded pipe without filler metal.

B31 CASE 153
Use of Alloy UNS S31803 Material in ASME B31.1 Construction

Approval Date: November 1989
Reaffirmation Date: November 1998

This case shall expire on November 30, 2001, unless previously annulled or reaffirmed

TABLE 1
ASTM PRODUCT SPECIFICATIONS

Piping	A 790-87
Tubing	A 789-87
Forgings	A 182-87
Plate, Sheet, and Strip	A 240-87
Bars and Shapes	A 276-87
Wrought Piping Fittings	A 815-86

Inquiry: May solution annealed austenitic–ferritic stainless steel, 22Cr–5½Ni–3Mo alloy (UNS S31803), materials be used in ASME B31.1 construction?

Reply: The product specifications shown in Table 1 for solution annealed ferritic–austenitic steel, 22Cr–5½Ni–3Mo alloy, may be used in the construction of power piping complying with the rules of ASME B31.1, provided the following additional requirements are met.

(1) These materials shall not be used for Boiler External Piping. See para. 100.1.2(A).

(2) Material shall be furnished in the heat treated condition. The heat treatment shall be performed at 1870°F to 2010°F with subsequent quenching in water or rapid cooling by other means.

(3) The allowable stress values shall be as follows:

For Metal Temperature Not Exceeding, °F	Max. Allowable Stress Values, ksi
100	22.5
200	22.5
300	21.7
400	20.9
500	20.4
600	20.2

(4) All longitudinal weld joints shall be completely examined by radiography. Radiographic examination shall be in accordance with the requirements of the ASME Boiler and Pressure Vessel Code, Section VIII, latest Edition, UW-51.

(5) The Welding Procedure Qualification and Performance Qualifications shall be conducted in accordance with Section IX. For qualifying welding procedures, the material shall be considered as P-No. 10H Gr. No. 1 of QW-422.

(6) Heat treatment after forming or fabrication is neither required nor prohibited [except as noted in para. (7)(e)], but any heat treatment applied shall be performed at 1870°F to 2010°F, followed by a rapid cool.

(7) Plate may be made into longitudinally welded pipe with filler metal added. Requirements of A 790 shall be met with the following modifications.

(a) The welds shall be made by an electric arc process involving the deposition of filler metal.

(b) The joints shall be full penetration double-welded or single-welded butt joints employing fusion welding processes, as defined under "Definitions," ASME Boiler and Pressure Vessel Code, Section IX. Where backing rings or strips are employed, the ring or strip material shall be of the same P-Number (QW-422 of Section IX) as the plate being joined. Backing rings or strips shall be completely removed after welding, prior to any required radiography, and the exposed weld surface shall be examined visually for conformance to the requirements of the following paragraph. Welds made by procedures employing backing rings which remain in place are prohibited.

(c) The weld surface on the O.D. side of the pipe shall be flush with the base plate or shall have a reasonably uniform crown in accordance with Table 127.4.2 in the Code. The weld surface on the I.D. side of the reinforcement may be removed at the manufacturer's option or by agreement between the manufacturer and purchaser. The contour of the reinforcement shall be reasonably smooth and free of irregularities. The deposited metal shall be fused uniformly into the plate surface. No concavity of contour is permitted unless the resulting thickness of the weld metal is equal to or greater than the minimum thickness of the adjacent base metal.

(d) Weld defects shall be repaired by removal to sound metal and rewelding. Subsequent heat treatment and inspection shall be as required on the original welds.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:56:20 2005

(e) All welding shall be done prior to heat treatment. After welding, solution heat treatment shall be in accordance with para. 2.

(8) CAUTIONARY NOTE: This Case allows the use of this material only for the temperature range given in para. (3). This material may be expected to exhibit embrittlement at room temperature after service above 600°F.

B31 CASE 162
Use of 21Cr–11Ni–N Alloy (S30815) for ASME B31.1 Construction

Approval Date: September 1992
Reaffirmation Date: September 1998

This case shall expire on September 30, 2001, unless previously annulled or reaffirmed

Inquiry: May solution annealed 21Cr–11Ni–N Alloy (S30815) seamless tubes and pipes, welded tubes and pipes, plate, sheet, strip, forging, and bar, conforming to the specifications of A 213, A 312, A 249, A 358, A 409, A 240, A 182 and A 479 be used in ASME B31.1 construction?

Reply: It is the opinion of the Committee that solution annealed 21Cr–11Ni–N Alloy (UNS S30815) seamless tubes and pipes, welded tubes and pipes, plate, sheet, strip, forging, and bar as described in the Inquiry may be used in ASME B31.1 construction provided:

(a) the material meets the chemical analysis and minimum tensile requirements detailed in the specification and noted here in Tables 1 and 2, respectively; otherwise conforming to all other requirements of the respective ASTM material specification;

(b) the maximum allowable design stress values shall be as given in Table 3, except that for welded tube and pipe, a joint efficiency factor, E_j, of 0.85 shall be used;

(c) welding shall be performed using any welding process or combination of processes capable of meeting the requirements of Section IX for P-No. 8, Group No. 2 materials. If postweld heat treatment is performed, the material shall be heated to 1560–1740°F for 10–15 minutes, followed by cooling in air.

TABLE 1
CHEMICAL REQUIREMENTS

Element	Percent
Carbon	0.05–0.10
Manganese, max	0.80
Phosphorus, max	0.40
Sulphur, max	0.030
Silicon	1.40–2.00
Nickel	10.0–12.0
Chromium	20.0–22.0
Nitrogen	0.14–0.20
Cerium	0.03–0.08
(Balance Iron)	

TABLE 2
MECHANICAL PROPERTY REQUIREMENTS

Tensile strength, min, ksi	87
Yield strength, 0.2% offset min, ksi	45
Elongated in 2 in. min, %	40

(d) heat treatment after forming is neither required nor prohibited. If heat treatment is used, the solution treatment shall consist of heating to a temperature of 1920°F to 2100°F and quenching in water or rapidly cooling by other means.

(e) this Case number shall be referenced in the documentation and marking of the material and recorded on the Manufacturer's Data Report.

NOTE:

(1) Due to the relatively low yield strength of these materials, these higher stress values were established at temperatures where the short time tensile properties govern to permit the use of these alloys where slightly greater deformation is acceptable. These higher stress values exceed 67%, but do not exceed 90% of the yield strength at temperature. Use of these stresses may result in dimensional changes due to permanent strain. These stress values are not recommended for flanges of gasketed joints or other applications where slight amounts of distortion can cause leakage or malfunction.

B31 CASE 163
Use of Ni–Cr–Co–Mo Alloy (UNS N06617) for ASME B31.1 Construction

Approval Date: July 1994
Reaffirmation Date: July 2000

This case shall expire on July 31, 2003, unless previously annulled or reaffirmed

Inquiry: May solution annealed Ni–Cr–Co–Mo alloy (UNS N06617) wrought plate, sheet, rod, bar, forgings, welded pipe, and seamless tube that meet the chemical composition requirements given in Table 1, the mechanical property requirements given in Table 2, and that further meet all other applicable requirements of the specifications listed in Table 3 be used in ASME B31.1, welded construction at temperatures up to and including 1500°F?

Reply: It is the opinion of the Committee that solution annealed Ni–Cr–Co–Mo alloy (UNS N06617) as described in the Inquiry may be used for construction, provided that all applicable requirements of ASME B31.1 and the following additional requirements are met.

(a) This material shall not be used for boiler external piping. See para. 100.1.2(A).

(b) Material shall be solution annealed at a temperature of 2100°F–2250°F and quenched in water or rapidly cooled by other means.

(c) The maximum allowable stress values for the material shall be those given in Table 4. For welded components, these values shall be multiplied by a factor of 0.85, except when 100% radiography is performed as noted in para. 136.4.5.

(d) Separate welding procedures and performance qualifications shall be required for this material. The welding procedure qualifications and performance qualification shall be conducted as prescribed in Section IX of the ASME Boiler and Pressure Vessel Code.

(e) Heat treatment after forming or fabrication is neither required nor prohibited. When heat treatment is performed, it shall be in accordance with (b) above.

(f) For external pressure design, refer to para. 104.1.3.

(g) For para. 104.1.2, which requires a temperature dependent parameter y, the y values are the same as nickel alloys listed in Table 104.1.2(A) and shall be as follows:

1150°F and below	$y = 0.4$
1200°F	$y = 0.5$
1250°F and above	$y = 0.7$

TABLE 1
CHEMICAL REQUIREMENTS

Element	Percent

B31 CASE 164
Use of Micro-Alloyed Carbon Steel Bar in ASME B31.1 Construction

Approval Date: September 1994
Reaffirmation Date: September 2000

This case shall expire on September 30, 2003, unless previously annulled or reaffirmed

Inquiry: May micro-alloyed carbon steel bar with additions of aluminum, vanadium, and nitrogen, a chemical composition as specified in Table 1, material properties as specified in Table 2, and otherwise conforming to the requirements of ASTM A 675 be used for ASME B31.1 construction?

Reply: It is the opinion of the Committee that the hot rolled bar material described in this Case may be used in welded and unwelded construction under the rules of ASME B31.1 provided the following additional requirements are met.

(a) The allowable stress values tabulated in Table 3 shall not be exceeded. The material shall not be used for design temperatures above or below those for which the allowable stress values are given in this Code Case.

(b) The material shall be limited to service application NPS 2 and smaller and supplied for manufacturer as round bar not exceeding 4 in. diameter.

(c) Separate welding procedures and performance qualifications shall be required for this material. The welding process shall be GTAW. The welding procedure qualification and performance qualification shall be conducted in accordance with the ASME Boiler and Pressure Vessel Code, Section IX.

(d) The material shall not be used for Boiler External Piping.

(e) The material described in this Inquiry is one of the highest tensile strength materials approved for use in ASME pressure component applications. The ASME materials data base has little fatigue data on these high strength materials. When calculating the allowable expansion stress range S_A using Eq. (1) in para. 102.3.2(C), the allowable stresses for A 106 Grade B shall be used. Further, fittings manufactured using this material shall be fatigue tested to assure comparable behavior with ASME materials to be used in installed assemblies.

(f) All applicable requirements of ASME B31.1 shall be met.

TABLE 1
CHEMICAL COMPOSITION
(Heat or Cast Analysis)

Element	Percent Weight
Carbon	0.19–0.26
Manganese	1.35–1.65
Phosphorus	0.040 max.
Sulfur	0.050 max.
Silicon	0.15–0.35
Vanadium	0.02–0.20
Aluminum	0.015–0.050
Nitrogen	0.03 max.

GENERAL NOTE: Addition of elements intended to enhance machinability, such as lead, selenium, bismuth and tellurium, is not allowed.

TABLE 2
MINIMUM MECHANICAL PROPERTIES

B31 CASE 165
Use of Alloy S32550 (25.5Cr–5.5Ni–3.5Mo–Cu), P-No. 10H in ASME B31.1 Construction

Approval Date: July 1995
Reaffirmation Date: July 2001

This Case shall expire on July 31, 2004, unless previously annulled or reaffirmed

Inquiry: May Alloy S32550 (25.5Cr–5.5Ni–3.5Mo–Cu), P-No. 10H, be used in power piping applications constructed in accordance with the B31.1 Code at temperatures up to and including 500°F?

Reply: Alloy S32550 may be used for ASME B31.1 construction to the specifications noted in this Code Case provided that all of the following requirements are met.

(a) THESE MATERIALS ARE NOT ACCEPTABLE FOR USE ON BOILER EXTERNAL PIPING — SEE PARA. 100.1.2.

(b) All applicable requirements of ASME B31.1 shall be met.

(c) Allowable stress values shown in Table 1 shall not be exceeded. These materials shall not be used at temperatures above those for which allowable stress values are given in this Code Case.

(d) All openings 4 in. and larger shall conform to para. 127.4.8 except that full penetration welds shall be used and separate reinforcing pads shall not be used.

(e) Butt weld joints shall be examined radiographically for their full length as prescribed in para. 136.4.5 when the wall thickness at the weld joint exceeds $1\frac{1}{2}$ in.

(f) Branch connection welds shall be radiographically (para. 136.4.5) or U.T. (para. 136.4.6) examined. See Table 136.4 when the size of the branch exceeds NPS 4.

(g) All welds where material thickness exceeds $\frac{3}{4}$ in. shall be examined by the liquid penetrant method.

(h) Pipe under external pressure shall meet requirements of para. 104.1.3.

(i) Heat treatment of product form is neither required nor prohibited but if performed shall be done in accordance with respective product specifications. See Table 132.

(j) Charpy impact testing shall be done in accordance with requirements of UHA-51(c)(2) when material wall thickness is greater than $\frac{3}{8}$ in.

B31 CASE 170
PWHT Exemptions for P-Nos. 4 and 5A Materials for ASME B31.1 Construction

Approval Date: March 1999

This Case shall expire on March 31, 2002, unless previously annulled or reaffirmed

Inquiry: What additional exemption to postweld heat treatment may be taken for P-Nos. 4 and 5A materials used for ASME B31.1 construction?

Reply: An additional exemption may be taken for nominal pipe sizes greater than NPS 4. All other rules for exemption in Table 132 for P-Nos. 4 and 5A shall remain in effect.

If this Case is used on boiler external piping, the Case number shall be identified in the Manufacturer's Data Report Form.

B31 CASE 173
Alternative Maximum Allowable Stresses Based on a Factor of Safety of 3.5 on Tensile Strength for ASME B31.1 Construction

Approval Date: May 2001

This Case shall expire on May 31, 2004, unless previously annulled or reaffirmed

Inquiry: New maximum allowable stresses based on a factor of 3.5 on tensile strength and the other existing B31.1 criteria for establishing maximum allowable stresses are under development for incorporation into the B31.1 Code. Until the development and incorporation of new maximum allowable stresses into B31.1 are completed, may alternative allowable stresses be used?

Reply: It is the opinion of the committee that allowable stresses other than those listed in B31.1, Appendix A may be used for B31.1 construction provided the following requirements are met.

(a) The materials shall be limited to ASTM materials listed in Table 126.1 that have a corresponding ASME material, as allowed by B31.1, para. 123.1 (D).

(b) Boiler external piping shall use maximum allowable stress values provided in ASME BPVC, Section II, Part D, 1999 Addenda, Tables 1A and 1B, as permitted for Section I design. Only ASME materials shall be used.

(c) Nonboiler external piping shall use maximum allowable stress values provided in either ASME BPVC, Section II, Part D, 1999 Addenda, Tables 1A and 1B as permitted for Section I design, or ASME BPVC, Section II, Part D, 1999 Addenda, Tables 1A and 1B as permitted for Section VIII, Division 1 design.

(d) For materials with a minimum tensile strength of over 70 ksi, the allowable expansion stress range S_A shall be calculated using allowable stresses for A 106 Grade B in Eq. (1) of para. 102.3.2(C) and Eq. (13) of para. 104.8.3.

(e) This Case number and the materials for which it applies shall be shown on the Manufacturer's Data Report (if applicable).

Date of Issuance: August 31, 2001
Mandatory Date: March 1, 2002

This Addenda was approved by The American National Standards Institute and designated ASME B31.3b-2001 on March 13, 2001.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment that provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable letters patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations of this document issued in accordance with the established ASME procedures and policies, which precludes the issuance of interpretations by individuals.

SUMMARY OF CHANGES

Addenda to the 1999 Edition of the Code are issued in the form of replacement pages. Revisions, additions, or deletions are incorporated directly into the affected pages. It is advisable, however, that all replaced pages be retained for reference.

Replace or insert the pages listed. Changes given below are identified on the pages by a margin note, **A01**, placed next to the affected area. Revisions to the 1999 Edition and 2000 Addenda are indicated by **99** and **A00**, respectively. For the listing below, the *Page* references the affected area. A margin note, **A01**, placed next to the heading indicates *Location*. Revisions are listed under *Change*.

Page	*Location*	*Change*

CHAPTER I
SCOPE AND DEFINITIONS

300 GENERAL STATEMENTS

(a) Identification. This Process Piping Code is a Section of the American Society of Mechanical Engineers Code for Pressure Piping, ASME B31, an American National Standard. It is published as a separate document for convenience of Code users.

A01 *(b) Responsibilities*

(1) Owner. The owner of a piping installation shall have overall responsibility for compliance with this Code, and for establishing the requirements for design, construction, examination, inspection, and testing which will govern the entire fluid handling or process installation of which the piping is a part. The owner is also responsible for designating piping in certain fluid services and for determining if a specific Quality System is to be employed. [See paras. 300(d)(4), (d)(5), (e), and Appendix Q.]

(2) Designer. The designer is responsible to the owner for assurance that the engineering design of piping complies with the requirements of this Code and with any additional requirements established by the owner.

(3) Manufacturer, Fabricator, and Erector. The manufacturer, fabricator, and erector of piping are responsible for providing materials, components, and workmanship in compliance with the requirements of this Code and of the engineering design.

(4) Owner's Inspector. The owner's Inspector (see para. 340) is responsible to the owner for ensuring that the requirements of this Code for inspection, examination, and testing are met. If a Quality System is specified by the owner to be employed, the owner's inspector is responsible for verifying that it is implemented.

(c) Intent of the Code

(1) It is the intent of this Code to set forth engineering requirements deemed necessary for safe design and construction of piping installations.

(2) This Code is not intended to apply to the operation, examination, inspection, testing, maintenance, or repair of piping that has been placed in service. The provisions of this Code may optionally be applied for those purposes, although other considerations may also be necessary.

(3) Engineering requirements of this Code, while considered necessary and adequate for safe design, generally employ a simplified approach to the subject. A designer capable of applying a more rigorous analysis shall have the latitude to do so; however, the approach must be documented in the engineering design and its validity accepted by the owner. The approach used shall provide details of design, construction, examination, inspection, and testing for the design conditions of para. 301, with calculations consistent with the design criteria of this Code. A00

(4) Piping elements should, insofar as practicable, conform to the specifications and standards listed in this Code. Piping elements neither specifically approved nor specifically prohibited by this Code may be used provided they are qualified for use as set forth in applicable Chapters of this Code.

(5) The engineering design shall specify any unusual requirements for a particular service. Where service requirements necessitate measures beyond those required by this Code, such measures shall be specified by the engineering design. Where so specified, the Code requires that they be accomplished.

(6) Compatibility of materials with the service and hazards from instability of contained fluids are not within the scope of this Code. See para. F323.

(d) Determining Code Requirements

(1) Code requirements for design and construction include fluid service requirements, which affect selection and application of materials, components, and joints. Fluid service requirements include prohibitions, limitations, and conditions, such as temperature limits or a requirement for safeguarding (see para. 300.2 and Appendix G). Code requirements for a piping system are the most restrictive of those which apply to any of its elements.

(2) For metallic piping not in Category M or high pressure fluid service, Code requirements are found in Chapters I through VI (the base Code), and fluid service requirements are found in:

(a) Chapter III for materials;

(b) Chapter II, Part 3, for components;

(c) Chapter II, Part 4, for joints.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:03 2005

(3) For nonmetallic piping and piping lined with nonmetals, all requirements are found in Chapter VII. (Paragraph designations begin with "A.")

(4) For piping in a fluid service designated by the owner as Category M (see para. 300.2 and Appendix M), all requirements are found in Chapter VIII. (Paragraph designations begin with "M.")

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:04 2005

from the hypotenuse of the largest right triangle that can be inscribed in the weld cross section to the root of the joint

(b) actual throat: the shortest distance from the root of a fillet weld to its face

(c) effective throat: the minimum distance, minus any reinforcement (convexity), between the weld root and the face of a fillet weld

toe of weld: the junction between the face of a weld and the base material

tube: see *pipe*

tungsten electrode: a nonfiller-metal electrode used in arc welding or cutting, made principally of tungsten

unbalanced piping system: see para. 319.2.2(b)

undercut: a groove melted into the base material adjacent to the toe or root of a weld and left unfilled by weld material

visual examination: see para. 344.2.1

weld: a localized coalescence of material wherein coalescence is produced either by heating to suitable temperatures, with or without the application of pressure, or by application of pressure alone, and with or without the use of filler material

weld reinforcement: weld material in excess of the specified weld size

welder: one who performs a manual or semi-automatic welding operation. (This term is sometimes erroneously used to denote a welding machine.)

welding operator: one who operates machine or automatic welding equipment

welding procedure: the detailed methods and practices involved in the production of a weldment

welding procedure specification (WPS): the document which lists the parameters to be used in construction of weldments in accordance with requirements of this Code

weldment: an assembly whose component parts are joined by welding

300.3 Nomenclature

Dimensional and mathematical symbols used in this Code are listed in Appendix J, with definitions and location references to each. Lowercase and uppercase English letters are listed alphabetically, followed by Greek letters.

300.4 Status of Appendices

Table 300.4 indicates for each Appendix of this Code whether it contains Code requirements, guidance, or supplemental information. See the first page of each Appendix for details.

TABLE 300.4
STATUS OF APPENDICES IN B31.3

Appendix	Title	Status
A	Stress Tables for Metallic Piping and Bolting Materials	Requirements
B	Stress Tables and Allowable Pressure Tables for Nonmetals	Requirements
C	Physical Properties of Piping Materials	Requirements (1)
D	Flexibility and Stress Intensification Factors	Requirements (1)
E	Reference Standards	Requirements
F	Precautionary Considerations	Guidance (2)
G	Safeguarding	Guidance (2)
H	Sample Calculations for Branch Reinforcement	Guidance
J	Nomenclature	Information
K	Allowable Stress for High Pressure Piping	Requirements (3)
L	Aluminum Alloy Pipe Flanges	Specification (5)
M	Guide to Classifying Fluid Services	Guidance (2)
Q	Quality System Program	Guidance (2)
V	Allowable Variations in Elevated Temperature Service	Guidance (2)
X	Metallic Bellows Expansion Joints	Requirements
Z	Preparation of Technical Inquiries	Requirements (4)

NOTES:
(1) Contains default requirements, to be used unless more directly applicable data are available.
(2) Contains no requirements but Code user is responsible for considering applicable items.
(3) Contains requirements applicable only when use of Chapter IX is specified.
(4) Contains administrative requirements.
(5) Contains pressure-temperature ratings, materials, dimensions, and markings of forged aluminum alloy flanges.

on measurements support the use of another temperature. Where piping is heated or cooled by tracing or jacketing, this effect shall be considered in establishing component design temperatures.

301.3.4 Internally Insulated Piping. The component design temperature shall be based on heat transfer calculations or tests.

301.4 Ambient Effects

See Appendix F, para. F301.4.

301.4.1 Cooling: Effects on Pressure. The cooling of a gas or vapor in a piping system may reduce the pressure sufficiently to create an internal vacuum. In such a case, the piping shall be capable of withstanding the external pressure at the lower temperature, or provision shall be made to break the vacuum.

301.4.2 Fluid Expansion Effects. Provision shall be made in the design either to withstand or to relieve increased pressure caused by the heating of static fluid in a piping component. See also para. 322.6.3(b)(2).

301.4.3 Atmospheric Icing. Where the design minimum temperature of a piping system is below 0°C (32°F), the possibility of moisture condensation and buildup of ice shall be considered and provisions made in the design to avoid resultant malfunctions. This applies to surfaces of moving parts of shutoff valves, control valves, pressure relief devices including discharge piping, and other components.

301.4.4 Low Ambient Temperature. Consideration shall be given to low ambient temperature conditions for displacement stress analysis.

301.5 Dynamic Effects

See Appendix F, para. F301.5.

301.5.1 Impact. Impact forces caused by external or internal conditions (including changes in flow rate, hydraulic shock, liquid or solid slugging, flashing, and geysering) shall be taken into account in the design of piping.

301.5.2 Wind. The effect of wind loading shall be taken into account in the design of exposed piping. The method of analysis may be as described in ASCE 7, Minimum Design Loads for Buildings and Other Structures, or the Uniform Building Code.

301.5.3 Earthquake. Piping shall be designed for earthquake-induced horizontal forces. The method of analysis may be as described in ASCE 7 or the Uniform Building Code. A01

301.5.4 Vibration. Piping shall be designed, arranged, and supported so as to eliminate excessive and harmful effects of vibration which may arise from such sources as impact, pressure pulsation, turbulent flow vortices, resonance in compressors, and wind. A01

301.5.5 Discharge Reactions. Piping shall be designed, arranged, and supported so as to withstand reaction forces due to let-down or discharge of fluids.

301.6 Weight Effects

The following weight effects, combined with loads and forces from other causes, shall be taken into account in the design of piping.

301.6.1 Live Loads. These loads include the weight of the medium transported or the medium used for test. Snow and ice loads due to both environmental and operating conditions shall be considered.

301.6.2 Dead Loads. These loads consist of the weight of piping components, insulation, and other superimposed permanent loads supported by the piping.

301.7 Thermal Expansion and Contraction Effects

The following thermal effects, combined with loads and forces from other causes, shall be taken into account in the design of piping. See also Appendix F, para. F301.7.

301.7.1 Thermal Loads Due to Restraints. These loads consist of thrusts and moments which arise when free thermal expansion and contraction of the piping are prevented by restraints or anchors.

301.7.2 Loads Due to Temperature Gradients. These loads arise from stresses in pipe walls resulting from large rapid temperature changes or from unequal temperature distribution as may result from a high heat flux through a comparatively thick pipe or stratified two-phase flow causing bowing of the line.

301.7.3 Loads Due to Differences in Expansion Characteristics. These loads result from differences in thermal expansion where materials with different thermal expansion coefficients are combined, as in bimetallic, lined, jacketed, or metallic–nonmetallic piping.

ature for bolting materials shall not exceed the lowest of the following:

A00 *(1)* except as provided in (3) below, the lower of one-fourth of specified minimum tensile strength at room temperature (S_T) and one-fourth of tensile strength at temperature;

A00 *(2)* except as provided in (3) below, the lower of two-thirds of specified minimum yield strength at room temperature (S_Y) and two-thirds of yield strength at temperature;

A00 *(3)* at temperatures below the creep range, for bolting materials whose strength has been enhanced by heat treatment or strain hardening, the lower of one-fifth of S_T and one-fourth of S_Y (unless these values are lower than corresponding values for annealed material, in which case the annealed values shall be used);

(4) two-thirds of the "yield strength at temperature" [see para. 302.3.2(f)];

(5) 100% of the average stress for a creep rate of 0.01% per 1000 hr;

(6) 67% of the average stress for rupture at the end of 100,000 hr;

(7) 80% of minimum stress for rupture at the end of 100,000 hr.

(b) Cast Iron. Basic allowable stress values at temperature for cast iron shall not exceed the lower of the following:

(1) one-tenth of the specified minimum tensile strength at room temperature;

(2) one-tenth of the tensile strength at temperature [see para. 302.3.2(f)].

(c) Malleable Iron. Basic allowable stress values at temperature for malleable iron shall not exceed the lower of the following:

(1) one-fifth of the specified minimum tensile strength at room temperature;

(2) one-fifth of the tensile strength at temperature [see para. 302.3.2(f)].

(d) Other Materials. Basic allowable stress values at temperature for materials other than bolting materials, cast iron, and malleable iron shall not exceed the lowest of the following:

A00 *(1)* the lower of one-third of S_T and one-third of tensile strength at temperature;

A00 *(2)* except as provided in (3) below, the lower of two-thirds of S_Y and two-thirds of yield strength at temperature;

A00 A01 *(3)* for austenitic stainless steels and nickel alloys having similar stress–strain behavior, the lower of two-thirds of S_Y and 90% of yield strength at temperature;

(4) 100% of the average stress for a creep rate of 0.01% per 1000 hr;

(5) 67% of the average stress for rupture at the end of 100,000 hr;

(6) 80% of the minimum stress for rupture at the end of 100,000 hr;

(7) for structural grade materials, the basic allowable stress shall be 0.92 times the lowest value determined in paras. 302.3.2(d)(1) through (6).

(8) In the application of these criteria, the yield strength at room temperature is considered to be $S_Y R_Y$, and the tensile strength at room temperature is considered to be $1.1 S_T R_T$. A00 A01

Application of stress values so determined is not recommended for flanged joints and other components in which slight deformation can cause leakage or malfunction. [These values are shown in italics or boldface in Table A-1, as explained in Note (4) to Appendix A Tables.] Instead, either 75% of the stress value in Table A-1 or two-thirds of the yield strength at temperature listed in the BPV Code, Section II, Part D, Table Y-1 should be used.

(e) Unlisted Materials. For a material which conforms to para. 323.1.2, the tensile (yield) strength at temperature shall be derived by multiplying the average expected tensile (yield) strength at temperature by the ratio of S_T (S_Y) divided by the average expected tensile (yield) strength at room temperature. A00 A01

302.3.3 Casting Quality Factor E_c

(a) General. The casting quality factors E_c defined herein shall be used for cast components not having pressure-temperature ratings established by standards in Table 326.1.

(b) Basic Quality Factors. Castings of gray and malleable iron, conforming to listed specifications, are assigned a basic casting quality factor E_c of 1.00 (due to their conservative allowable stress basis). For most other metals, static castings which conform to the material specification and have been visually examined as required by MSS SP-55, Quality Standard for Steel Castings for Valves, Flanges and Fittings and Other Piping Components — Visual Method, are assigned a basic casting quality factor E_c of 0.80. Centrifugal castings which meet specification requirements only for chemical analysis, tensile, hydrostatic, and flattening tests, and visual examination are assigned a basic casting quality factor of 0.80. Basic casting quality factors are tabulated for listed specifications in Table A-1A.

(c) Increased Quality Factors. Casting quality factors may be increased when supplementary examinations are performed on each casting. Table 302.3.3C states the increased casting quality factors E_c which may

TABLE 302.3.3C[4]
INCREASED CASTING QUALITY FACTORS, E_C

Supplementary Examination in Accordance With Note(s)	Factor, E_C
(1)	0.85
(2)(a) or (2)(b)	0.85
(3)(a) or (3)(b)	0.95
(1) and (2)(a) or (2)(b)	0.90
(1) and (3)(a) or (3)(b)	1.00
(2)(a) or (2)(b) and (3)(a) or (3)(b)	1.00

NOTES:
(1) Machine all surfaces to a finish of 6.3 μm R_a (250 μin. R_a per ASME B46.1), thus increasing the effectiveness of surface examination.
(2) (a) Examine all surfaces of each casting (magnetic material only) by the magnetic particle method in accordance with ASTM E 709. Judge acceptability in accordance with MSS SP-53, using reference photos in ASTM E 125.
(b) Examine all surfaces of each casting by the liquid penetrant method, in accordance with ASTM E 165. Judge acceptability of flaws and weld repairs in accordance with Table 1 of MSS SP-53, using ASTM E 125 as a reference for surface flaws.
(3) (a) Fully examine each casting ultrasonically in accordance with ASTM E 114, accepting a casting only if there is no evidence of depth of defects in excess of 5% of wall thickness.
(b) Fully radiograph each casting in accordance with ASTM E 142. Judge in accordance with the stated acceptance levels in Table 302.3.3D.
(4) Titles of standards referenced in this Table are as follows:
ASTM
E 114 Practice for Ultrasonic Pulse-Echo Straight-Beam Testing by the Contact Method
E 125 Reference Photographs for Magnetic Particle Indications on Ferrous Castings
E 142 Method for Controlling Quality of Radiographic Testing
E 165 Practice for Liquid Penetrant Inspection Method
E 709 Practice for Magnetic Particle Examination
ASME
B46.1 Surface Texture (Surface Roughness, Waviness and Lay)
MSS
SP-53 Quality Standard for Steel Castings for Valves, Flanges and Fittings and Other Piping Components—Magnetic Particle Examination Method

TABLE 302.3.3D[1]
ACCEPTANCE LEVELS FOR CASTINGS

Material Examined Thickness, T	Applicable Standard	Acceptance Level (or Class)	Acceptable Discontinuities
Steel $T \leq 25$ mm (1 in.)	ASTM E 446	1	Types A, B, C
Steel $T > 25$ mm, ≤ 51 mm (2 in.)	ASTM E 446	2	Types A, B, C
Steel $T > 51$ mm, ≤ 114 mm ($4\frac{1}{2}$ in.)	ASTM E 186	2	Categories A, B, C
Steel $T > 114$ mm, ≤ 305 mm (12 in.)	ASTM E 280	2	Categories A, B, C
Aluminum & magnesium	ASTM E 155	...	Shown in reference radiographs
Copper, Ni–Cu	ASTM E 272	2	Codes A, Ba, Bb
Bronze	ASTM E 310	2	Codes A and B

NOTE:
(1) Titles of standards referenced in this Table are as follows:
ASTM
E 155 Reference Radiographs for Inspection of Aluminum and Magnesium Castings
E 186 Reference Radiographs for Heavy-Walled [2 to 4-$\frac{1}{2}$-in. (51 to 114-mm)] Steel Castings
E 272 Reference Radiographs for High-Strength Copper-Base and Nickel-Copper Castings
E 280 Reference Radiographs for Heavy-Walled [4-$\frac{1}{2}$ to 12-in. (114 to 305-mm)] Steel Castings
E 310 Reference Radiographs for Tin Bronze Castings
E 446 Reference Radiographs for Steel Castings Up to 2 in. (51 mm) in Thickness

be used for various combinations of supplementary examination. Table 302.3.3D states the acceptance criteria for the examination methods specified in the Notes to Table 302.3.3C. Quality factors higher than those shown in Table 302.3.3C do not result from combining tests 2a and 2b, or 3a and 3b. In no case shall the quality factor exceed 1.00.

Several of the specifications in Appendix A require machining of all surfaces and/or one or more of these supplementary examinations. In such cases, the appropriate increased quality factor is shown in Table A-1A.

302.3.4 Weld Joint Quality Factor, E_j

(a) Basic Quality Factors. The weld joint quality factors E_j tabulated in Table A-1B are basic factors for straight or spiral longitudinal welded joints for pressure-containing components as shown in Table 302.3.4.

(b) Increased Quality Factors. Table 302.3.4 also indicates higher joint quality factors which may be substituted for those in Table A-1B for certain kinds of welds if additional examination is performed beyond that required by the product specification.

302.3.5 Limits of Calculated Stresses Due to Sustained Loads and Displacement Strains

(a) Internal Pressure Stresses. Stresses due to internal pressure shall be considered safe when the wall

Copyright by the American Society Of Mechanical Engineers

(3) cast, with factor $E_c \geq 0.90$.[8]

A00 (b) Fittings conforming to MSS SP-43, MSS SP-119, and proprietary "Type C" lap-joint stub-end welding fittings shall not be used under severe cyclic conditions.

306.2 Pipe Bends

306.2.1 General. A pipe bend made in accordance with paras. 332.2.1 and 332.2.2, and verified for pressure design in accordance with para. 304.2.1, is suitable for the same service as the pipe from which it is made.

306.2.2 Corrugated and Other Bends. Bends of other designs (such as creased or corrugated) shall be qualified for pressure design as required by para. 304.7.2.

306.2.3 Bends for Severe Cyclic Conditions. A pipe bend designed as creased or corrugated shall not be used under severe cyclic conditions.

306.3 Miter Bends

306.3.1 General. Except as stated in para. 306.3.2, a miter bend made in accordance with para. 304.2.3 and welded in accordance with para. 311.1 is suitable for use in Normal Fluid Service.

306.3.2 Miter Bends for Category D Fluid Service. A miter bend which makes a change in direction at a single joint (angle α in Fig. 304.2.3) greater than 45 deg, or is welded in accordance with para. 311.2.1, may be used only for Category D Fluid Service.

306.3.3 Miter Bends for Severe Cyclic Conditions. A miter bend to be used under severe cyclic conditions shall be made in accordance with para. 304.2.3 and welded in accordance with para. 311.2.2, and shall have an angle α (see Fig. 304.2.3) $\leq$ 22.5 deg.

A01 ### 306.4 Laps

The following requirements do not apply to fittings conforming to para. 306.1, specifically lap-joint stub ends conforming to ASME B16.9, nor to laps integrally hot-forged on pipe ends, except as noted in paras. 306.4.3 and 306.4.4(a).

306.4.1 Fabricated Laps. A fabricated lap is suitable for use in Normal Fluid Service, provided that all of the following requirements are met.

(a) The outside diameter of the lap shall be within the dimensional tolerances of the corresponding ASME B16.9 lap-joint stub end.

(b) The lap thickness shall be at least equal to the nominal wall thickness of the pipe to which it is attached.

(c) The lap material shall be listed in Table A-1 and shall have an allowable stress at least as great as that of the pipe.

(d) Welding shall be in accordance with para. 311.1 and fabrication shall be in accordance with para. 328.5.5.

306.4.2 Flared Laps. See para. 308.2.5 for requirements of lapped flanges for use with flared laps. A flared lap is suitable for use in Normal Fluid Service, provided that all of the following requirements are met.

(a) The pipe used shall be of a specification and grade listed in Table A-1 suitable for forming without cracks, surface buckling, or other defects.

(b) The outside diameter of the lap shall be within the dimensional tolerances of the corresponding ASME B16.9 lap-joint stub end.

(c) The radius of fillet shall not exceed 3 mm ($\frac{1}{8}$ in.).

(d) The lap thickness at any point shall be at least 95% of the minimum pipe wall thickness T multiplied by the ratio of the pipe outside diameter to the diameter at which the lap thickness is measured.

(e) Pressure design shall be qualified as required by para. 304.7.2.

306.4.3 Forged Laps. A lap integrally hot-forged on a pipe end is suitable for Normal Fluid Service only when the requirements of para. 332 are met. Its dimensions shall conform to those for lap-joint stub ends given in ASME B16.9.

306.4.4 Laps for Severe Cyclic Conditions

(a) A forged lap-joint stub end per para. 306.1 or a lap integrally hot-forged on a pipe end per para. 306.4.3 may be used under severe cyclic conditions.

(b) A fabricated lap to be used under severe cyclic conditions shall conform to the requirements of para. 306.4.1, except that welding shall be in accordance with para. 311.2.2. A fabricated lap shall conform to a detail shown in Fig. 328.5.5, sketch (d) or (e).

(c) A flared lap is not permitted under severe cyclic conditions.

306.5 Fabricated Branch Connections

The following requirements do not apply to fittings conforming to para. 306.1.

306.5.1 General. A fabricated branch connection made and verified for pressure design in accordance with para. 304.3, and welded in accordance with para. 311.1, is suitable for use in Normal Fluid Service.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:05 2005

306.5.2 Fabricated Branch Connections for Severe Cyclic Conditions. A fabricated branch connection to be used under severe cyclic conditions shall conform to the requirements of para. 306.5.1, except that welding shall be in accordance with para. 311.2.2, with fabrication limited to a detail equivalent to Fig. 328.5.4D sketch (2) or (4), or to Fig. 328.5.4E.

307 VALVES AND SPECIALTY COMPONENTS

The following requirements for valves shall also be met as applicable by other pressure containing piping

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:06 2005

components, such as traps, strainers, and separators. See also Appendix F, paras. F301.4 and F307.

307.1 General

307.1.1 Listed Valves. A listed valve is suitable for use in Normal Fluid Service, except as stated in para. 307.2.

307.1.2 Unlisted Valves. Unlisted valves may be used only in accordance with para. 302.2.3. Unless pressure-temperature ratings are established by the method set forth in Appendix F to ASME B16.34, pressure design shall be qualified as required by para. 304.7.2.

307.2 Specific Requirements

A bolted bonnet valve whose bonnet is secured to the body by less than four bolts, or by a U-bolt, may be used only for Category D Fluid Service.

308 FLANGES, BLANKS, FLANGE FACINGS, AND GASKETS

308.1 General

308.1.1 Listed Components. A listed flange, blank, or gasket is suitable for use in Normal Fluid Service, except as stated elsewhere in para. 308.

308.1.2 Unlisted Components. Unlisted flanges, blanks, and gaskets may be used only in accordance with para. 302.2.3.

(99) ### 308.2 Specific Requirements for Flanges

See Appendix F, paras. F308.2 and F312.

308.2.1 Slip-On Flanges

(a) A slip-on flange shall be double-welded as shown in Fig. 328.5.2B when the service is:

(1) subject to severe erosion, crevice corrosion, or cyclic loading;

(2) flammable, toxic, or damaging to human tissue;

(3) under severe cyclic conditions;

(4) at temperatures below −101°C (−150°F).

(b) The use of slip-on flanges should be avoided where many large temperature cycles are expected, particularly if the flanges are not insulated.

(c) Slip-on Flanges as Lapped Flanges. A slip-on flange may be used as a lapped flange only as shown in Table 308.2.1 unless pressure design is qualified in accordance with para. 304.5.1. A corner radius or bevel shall conform to one of the following as applicable:

(1) for an ASME B16.9 lap joint stub end or a forged lap (see para. 306.4.3) the corner radius shall be as specified in ASME B16.5, Tables 9 and 12, dimension *r*.

(2) for a fabricated lap, the corner bevel shall be at least half the nominal thickness of the pipe to which the lap is attached (see Fig. 328.5.5).

(3) for a flared lap see para. 308.2.5.

TABLE 308.2.1
PERMISSIBLE SIZES/RATING CLASSES FOR SLIP-ON FLANGES USED AS LAPPED FLANGES[1]

Rating		Maximum Flange Size	
PN	Class	DN	NPS
20	150	300	12
50	300	200	8

NOTE:
(1) Actual thickness of flange at bolt circle shall at least equal minimum required flange thickness in ASME B16.5.

308.2.2 Expanded-Joint Flanges. A flange having an expanded-joint insert is subject to the requirements for expanded joints in para. 313.

308.2.3 Socket Welding and Threaded Flanges. A socket welding flange is subject to the requirements for socket welds in para. 311.2.4. A threaded flange is subject to the requirements for threaded joints in para. 314.4.

308.2.4 Flanges for Severe Cyclic Conditions. Unless it is safeguarded, a flange to be used under severe cyclic conditions shall be welding neck conforming to ASME B16.5 or ASME B16.47, or a similarly proportioned flange designed in accordance with para. 304.5.1.

308.2.5 Flanges for Flared Metallic Laps. For a flange used with a flared metallic lap (para. 306.4.2), the intersection of face and bore shall be beveled or rounded approximately 3 mm (⅛ in.). See also para. 308.2.1(c).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:06 2005

A01 *(c)* is of uniform size, has no more than two points of fixation, no intermediate restraints, and falls within the limitations of empirical Eq. (16):[9]

$$\frac{Dy}{(L-U)^2} \le K_1 \qquad (16)$$

where

D = outside diameter of pipe, mm (in.)
y = resultant of total displacement strains, mm (in.), to be absorbed by the piping system
L = developed length of piping between anchors, m (ft)
U = anchor distance, straight line between anchors, m (ft)
K_1 = 208,000 S_A/E_a, $(mm/m)^2$
= 30 S_A/E_a, $(in./ft)^2$

where

S_A = allowable displacement stress range per Eq. (1a), MPa (ksi)
E_a = reference modulus of elasticity at 21°C (70°F), MPa (ksi)

319.4.2 Formal Analysis Requirements

(a) Any piping system which does not meet the criteria in para. 319.4.1 shall be analyzed by a simplified, approximate, or comprehensive method of analysis, as appropriate.

(b) A simplified or approximate method may be applied only if used within the range of configurations for which its adequacy has been demonstrated.

(c) Acceptable comprehensive methods of analysis include analytical and chart methods which provide an evaluation of the forces, moments, and stresses caused by displacement strains (see para. 319.2.1).

(d) Comprehensive analysis shall take into account stress intensification factors for any component other than straight pipe. Credit may be taken for the extra flexibility of such a component.

[9] *WARNING*: No general proof can be offered that this equation will yield accurate or consistently conservative results. It is not applicable to systems used under severe cyclic conditions. It should be used with caution in configurations such as unequal leg U-bends ($L/U > 2.5$) or near-straight "sawtooth" runs, or for large thin-wall pipe ($i \ge 5$), or where extraneous displacements (not in the direction connecting anchor points) constitute a large part of the total displacement. There is no assurance that terminal reactions will be acceptably low, even if a piping system falls within the limitations of Eq. (16).

319.4.3 Basic Assumptions and Requirements. Standard assumptions specified in para. 319.3 shall be followed in all cases. In calculating the flexibility of a piping system between anchor points, the system shall be treated as a whole. The significance of all parts of the line and of all restraints introduced for the purpose of reducing moments and forces on equipment or small branch lines, and also the restraint introduced by support friction, shall be recognized. Consider all displacements, as outlined in para. 319.2.1, over the temperature range defined by para. 319.3.1.

319.4.4 Flexibility Stresses

(a) The range of bending and torsional stresses shall be computed using the reference modulus of elasticity at 21°C (70°F), E_a, except as provided in para. 319.2.2(b)(4), and then combined in accordance with Eq. (17) to determine the computed displacement stress range S_E, which shall not exceed the allowable stress range S_A in para. 302.3.5(d).

$$S_E = \sqrt{S_b^2 + 4S_t^2} \qquad (17)$$

where

S_b = resultant bending stress
S_t = torsional stress
= $M_t/2Z$
M_t = torsional moment
Z = section modulus of pipe

(b) The resultant bending stresses S_b to be used in Eq. (17) for elbows, miter bends, and full size outlet branch connections (Legs 1, 2, and 3) shall be calculated in accordance with Eq. (18), with moments as shown in Figs. 319.4.4A and 319.4.4B.

$$S_b = \frac{\sqrt{(i_i M_i)^2 + (i_o M_o)^2}}{Z} \qquad (18)$$

where

S_b = resultant bending stress
i_i = in-plane stress intensification factor from Appendix D
i_o = out-plane stress intensification factor from Appendix D
M_i = in-plane bending moment
M_o = out-plane bending moment
Z = section modulus of pipe

(c) The resultant bending stress S_b to be used in Eq. (17) for reducing outlet branch connections shall be calculated in accordance with Eqs. (19) and (20), with moments as shown in Fig. 319.4.4B.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:06 2005

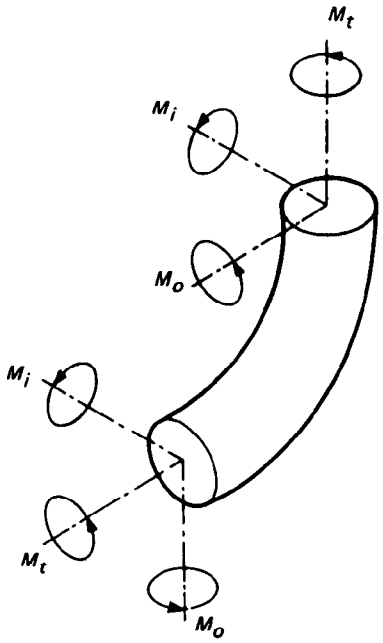

FIG. 319.4.4A MOMENTS IN BENDS

For header (Legs 1 and 2):

$$S_b = \frac{\sqrt{(i_i M_i)^2 + (i_o M_o)^2}}{Z} \qquad (19)$$

For branch (Leg 3):

$$S_b = \frac{\sqrt{(i_i M_i)^2 + (i_o M_o)^2}}{Z_e} \qquad (20)$$

where

S_b = resultant bending stress
Z_e = effective section modulus for branch,
$= \pi r_2^2 T_S$ (21)
r_2 = mean branch cross-sectional radius
T_S = effective branch wall thickness, lesser of $\overline{T}_h$ and $(i_i)(\overline{T}_b)$
$\overline{T}_h$ = thickness of pipe matching run of tee or header exclusive of reinforcing elements
$\overline{T}_b$ = thickness of pipe matching branch
i_o = out-plane stress intensification factor (Appendix D)
i_i = in-plane stress intensification factor (Appendix D)

319.4.5 Required Weld Quality Assurance. Any weld at which S_E exceeds $0.8S_A$ (as defined in para. 302.3.5) and the equivalent number of cycles N exceeds 7000 shall be fully examined in accordance with para. 341.4.3.

319.5 Reactions

Reaction forces and moments to be used in design of restraints and supports for a piping system, and in evaluating the effects of piping displacements on connected equipment, shall be based on the reaction range R for the extreme displacement conditions, considering the temperature range defined in para. 319.3.1(b), and using E_a. The designer shall consider instantaneous maximum values of forces and moments in the original and extreme displacement conditions (see para. 319.2.3), as well as the reaction range, in making these evaluations.

319.5.1 Maximum Reactions for Simple Systems. For a two-anchor piping system without intermediate restraints, the maximum instantaneous values of reaction forces and moments may be estimated from Eqs. (22) and (23).

(a) For Extreme Displacement Conditions, R_m. The temperature for this computation is the maximum or minimum metal temperature defined in para. 319.3.1(b), whichever produces the larger reaction:

$$R_m = R\left(1 - \frac{2C}{3}\right)\frac{E_m}{E_a} \qquad (22)$$

where

C = cold-spring factor varying from zero for no cold spring to 1.0 for 100% cold spring. (The factor two-thirds is based on experience which shows that specified cold spring cannot be fully assured, even with elaborate precautions.)
E_a = reference modulus of elasticity at 21°C (70°F)
E_m = modulus of elasticity at maximum or minimum metal temperature
R = range of reaction forces or moments (derived from flexibility analysis) corresponding to the full displacement stress range and based on E_a
R_m = estimated instantaneous maximum reaction force or moment at maximum or minimum metal temperature

(b) For Original Condition, R_a. The temperature for

CHAPTER IV
STANDARDS FOR PIPING COMPONENTS

326 DIMENSIONS AND RATINGS OF COMPONENTS

326.1 Dimensional Requirements

326.1.1 Listed Piping Components. Dimensional standards[1] for piping components are listed in Table 326.1. Dimensional requirements contained in specifications listed in Appendix A shall also be considered requirements of this Code.

326.1.2 Unlisted Piping Components. Dimensions of piping components not listed in Table 326.1 or Appendix A shall conform to those of comparable listed components insofar as practicable. In any case, dimensions shall be such as to provide strength and performance equivalent to standard components except as provided in paras. 303 and 304.

326.1.3 Threads. The dimensions of piping connection threads not otherwise covered by a governing component standard or specification shall conform to the requirements of applicable standards listed in Table 326.1 or Appendix A.

[1] It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and address of sponsoring organizations, are shown in Appendix E.

326.2 Ratings of Components

326.2.1 Listed Components. The pressure-temperature ratings of components listed in Table 326.1 are accepted for pressure design in accordance with para. 303.

326.2.2 Unlisted Components. The pressure-temperature ratings of unlisted piping components shall conform to the applicable provisions of para. 304.

326.3 Reference Documents A00

The documents listed in Table 326.1 contain references to codes, standards, and specifications not listed in Table 326.1. Such unlisted codes, standards, and specifications shall be used only in the context of the listed documents in which they appear.

The design, materials, fabrication, assembly, examination, inspection, and testing requirements of this Code are not applicable to components manufactured in accordance with the documents listed in Table 326.1, unless specifically stated in this Code, or the listed document.

Bronze Pipe Flanges and Flanged Fittings Class 150, 300, 400, 600, 900, 1500, and 2500 and Flanged Fittings, Class 150 and 300	*ASME B16.24
Cast Copper Alloy Fittings for Flared Copper Tubes	*ASME B16.26
Wrought Steel Buttwelding Short Radius Elbows and Returns [Note (5)]	*ASME B16.28
Valves-Flanged, Threaded, and Welding End	*ASME B16.34
Orifice Flanges, Class 300, 600, 900, 1500, and 2500	*ASME B16.36
Malleable Iron Threaded Pipe Unions, Class 150, 250, and 300	*ASME B16.39
Ductile Iron Pipe Flanges and Flanged Fittings, Class 150 and 300	*ASME B16.42
Large Diameter Steel Flanges, NPS 26 Through NPS 60	*ASME B16.47
Flanged Steel Pressure-Relief Valves	API 526
Wafer and Wafer-Lug Check Valves	*API 594
Metal Plug Valves—Flanged and Welding Ends	API 599
Steel Gate Valves — Flanged and Buttwelding Ends, Bolted and Pressure Seal Bonnets	API 600
Compact Steel Gate Valves — Flanged, Threaded, Welding and Extended Body Ends	API 602
Class 150, Cast, Corrosion-Resistant, Flanged-End Gate Valves	*API 603
Metal Ball Valves-Flanged, Threaded, and Welding End	API 608
Lug- and Wafer-Type Butterfly Valves	*API 609
Ductile-Iron and Gray-Iron Fittings, 3 Inch Through 48 Inch (75 mm Through 1200 mm), for Water and Other Liquids	*AWWA C110
Flanged Ductile-Iron with Ductile-Iron or Gray-Iron Threaded Flanges	*AWWA C115
Steel Pipe Flanges for Water works Service, sizes 4 inch Through 144 inch (100 mm Through 3,600 mm)	*AWWA C207
Dimensions for Fabricated Steel Water Pipe Fittings	*AWWA C208
Metal-Seated Gate Valves for Water Supply Service	*AWWA C500
Rubber-Seated Butterfly Valves	*AWWA C504
Standard Finishes for Contact Faces of Pipe Flanges and Connecting-End Flanges of Valves and Fittings	MSS SP-6
Spot Facing for Bronze, Iron and Steel Flanges	MSS SP-9
Standard Marking Systems for Valves, Fittings, Flanges, and Unions	MSS SP-25
Class 150 (PN 20) Corrosion Resistant Gate, Globe, Angle and Check Valves With Flanged and Butt Weld Ends	MSS SP-42
Wrought Stainless Steel Butt-Welding Fittings Including Reference to Other Corrosion Resistant Materials	MSS SP-43
Steel Pipe Line Flanges	MSS SP-44

TABLE 326.1 (CONT'D)

NOTES:
(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.
(2) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.
(3) This standard allows the use of unlisted materials; see para. 323.1.2.
(4) This standard allows straight pipe threads in sizes ≤ DN 15 (NPS ½); see para. 314.2.1(d).
(5) *Cautionary Note:* Pressure ratings of components manufactured in accordance with editions prior to the 1994 edition of this standard were derated to 80% of equivalent seamless pipe. This derating is no longer required for components manufactured in accordance with the 1994 Edition.
(6) See also Appendix A.
(7) MSS SP-119 includes three classes of fittings: MP, MARINE, and CR. Only the MP class fittings are considered a "Listed Component" for the purpose of this Code. *Cautionary Note*: See MSS SP-119 (Section 6) for special provisions concerning ratings. (In accordance with MSS SP-119, the pressure ratings for MP class fittings are 87.5% of those calculated for straight seamless pipe of *minimum* wall thickness.)

Criterion Value Notes for Table 341.3.2

Symbol	Criterion Measure	Acceptable Value Limits [Note (6)]	
A	Extent of imperfection	Zero (no evident imperfection)	
B	Depth of incomplete penetration Cumulative length of incomplete penetration	≤ 1 mm (1/32 in.) and ≤ $0.2\overline{T}_w$ ≤ 38 mm (1.5 in.) in any 150 mm (6 in.) weld length	
C	Depth of lack of fusion and incomplete penetration Cumulative length of lack of fusion and incomplete penetration [Note (7)]	≤ $0.2\overline{T}_w$ ≤ 38 mm (1.5 in.) in any 150 mm (6 in.) weld length	
D	Size and distribution of internal porosity	See BPV Code, Section VIII, Division 1, Appendix 4	
E	Size and distribution of internal porosity	For $\overline{T}_w$ ≤ 6 mm (1/4 in.), limit is same as D For $\overline{T}_w$ > 6 mm (1/4 in.), limit is 1.5 × D	
F	Slag inclusion, tungsten inclusion, or elongated indication Individual length Individual width Cumulative length	 ≤ $\overline{T}_w/3$ ≤ 2.5 mm (3/32 in.) and ≤ $\overline{T}_w/3$ ≤ $\overline{T}_w$ in any $12\overline{T}_w$ weld length	
G	Slag inclusion, tungsten inclusion, or elongated indication Individual length Individual width Cumulative length	 ≤ $2\overline{T}_w$ ≤ 3 mm (1/8 in.) and ≤ $\overline{T}_w/2$ ≤ $4\overline{T}_w$ in any 150 mm (6 in.) weld length	
H	Depth of undercut	≤ 1 mm (1/32 in.) and ≤ $\overline{T}_w/4$	
I	Depth of undercut	≤ 1.5 mm (1/16 in.) and ≤ [$\overline{T}_w/4$ or 1 mm (1/32 in.)]	
J	Surface roughness	≤ 500 min. Ra per ASME B46.1	
K	Depth of root surface concavity	Total joint thickness, incl. weld reinf., ≥ $\overline{T}_w$	
L	Height of reinforcement or internal protrusion [Note (8)] in any plane through the weld shall be within limits of the applicable height value in the tabulation at right, except as provided in Note (9). Weld metal shall merge smoothly into the component surfaces.	For $\overline{T}_w$, mm (in.) ≤ 6 (1/4) > 6 (1/4), ≤ 13 (1/2) > 13 (1/2), ≤ 25 (1) > 25 (1)	Height, mm (in.) ≤ 1.5 (1/16) ≤ 3 (1/8) ≤ 4 (5/32) ≤ 5 (3/16)
M	Height of reinforcement or internal protrusion [Note (8)] as described in L. Note (9) does not apply.	Limit is twice the value applicable for L above	

X = required examination NA = not applicable ... = not required

Notes follow on next page

test. Test temperature is important in this regard and must be considered when the designer chooses the material of construction. See para. 345.2.2(c) and Appendix F, para. F323.4.

345.5.2 Pressure Relief Device. A pressure relief device shall be provided, having a set pressure not higher than the test pressure plus the lesser of 345 kPa (50 psi) or 10% of the test pressure.

345.5.3 Test Fluid. The gas used as test fluid, if not air, shall be nonflammable and nontoxic.

345.5.4 Test Pressure. The test pressure shall be 110% of design pressure.

345.5.5 Procedure. The pressure shall be gradually increased until a gage pressure which is the lesser of one-half the test pressure or 170 kPa (25 psi) is attained, at which time a preliminary check shall be made, including examination of joints in accordance with para. 341.4.1(a). Thereafter, the pressure shall be gradually increased in steps until the test pressure is reached, holding the pressure at each step long enough to equalize piping strains. The pressure shall then be reduced to the design pressure before examining for leakage in accordance with para. 345.2.2(a).

345.6 Hydrostatic-Pneumatic Leak Test

If a combination hydrostatic-pneumatic leak test is used, the requirements of para. 345.5 shall be met, and the pressure in the liquid filled part of the piping shall not exceed the limits stated in para. 345.4.2.

345.7 Initial Service Leak Test

This test is applicable only to piping in Category D Fluid Service, at the owner's option. See para. 345.1(a).

345.7.1 Test Fluid. The test fluid is the service fluid.

345.7.2 Procedure. During or prior to initial operation, the pressure shall be gradually increased in steps until the operating pressure is reached, holding the pressure at each step long enough to equalize piping strains. A preliminary check shall be made as described in para. 345.5.5 if the service fluid is a gas or vapor.

345.7.3 Examination for Leaks. In lieu of para. 345.2.2(a), it is permissible to omit examination for leakage of any joints and connections previously tested in accordance with this Code.

345.8 Sensitive Leak Test

The test shall be in accordance with the Gas and Bubble Test method specified in the BPV Code, Section V, Article 10, or by another method demonstrated to have equal sensitivity. Sensitivity of the test shall be not less than 10^{-3} atm·ml/sec under test conditions.

(a) The test pressure shall be at least the lesser of 105 kPa (15 psi) gage, or 25% or the design pressure.

(b) The pressure shall be gradually increased until a gage pressure the lesser of one-half the test pressure or 170 kPa (25 psi) is attained, at which time a preliminary check shall be made. Then the pressure shall be gradually increased in steps until the test pressure is reached, the pressure being held long enough at each step to equalize piping strains.

345.9 Alternative Leak Test

The following procedures and leak test method may be used only under the conditions stated in para. 345.1(c).

345.9.1 Examination of Welds. Welds, including those used in the manufacture of welded pipe and fittings, which have not been subjected to hydrostatic or pneumatic leak tests in accordance with this Code, shall be examined as follows.

(a) Circumferential, longitudinal, and spiral groove welds shall be 100% radiographed in accordance with para. 344.5 or 100% ultrasonically examined in accordance with para. 344.6. A01

(b) All welds, including structural attachment welds, not covered in (a) above, shall be examined using the liquid penetrant method (para. 344.4) or, for magnetic materials, the magnetic particle method (para. 344.3).

345.9.2 Flexibility Analysis. A flexibility analysis of the piping system shall have been made in accordance with the requirements of para. 319.4.2 (b), if applicable, or (c) and (d).

345.9.3 Test Method. The system shall be subjected to a sensitive leak test in accordance with para. 345.8.

346 RECORDS

346.2 Responsibility

It is the responsibility of the piping designer, the manufacturer, the fabricator, and the erector, as applicable, to prepare the records required by this Code and by the engineering design.

Copyright by the American Society Of Mechanical Engineers

A302.3.3 Limits of Calculated Stresses due to Sustained Loads[1]

(a) Internal Pressure Stresses. Limits of stress due to internal pressure are covered in para. A304.

(b) External Pressure Stresses. Stresses due to uniform external pressure shall be considered safe when the wall thickness of the component and its means of stiffening have been qualified as required by para. A304.7.2.

(c) External Loading Stresses. Design of piping under external loading shall be based on the following:

(1) Thermoplastic Piping. ASTM D 2321 or AWWA C900;

(2) Reinforced Thermosetting Resin (RTR) and Reinforced Plastic Mortar (RPM) Piping. ASTM D 3839 or Appendix A of AWWA C950;

(3) strain and possible buckling shall be considered when determining the maximum allowable deflection in (1) or (2) above, but in no case shall the allowable diametral deflection exceed 5% of the pipe inside diameter;

(4) nonmetallic piping not covered in (1) or (2) above shall be subjected to a crushing or three-edge bearing test in accordance with ASTM C 14 or C 301; the allowable load shall be 25% of the minimum value obtained.

A302.3.4 Limits of Calculated Stresses due to Occasional Loads

(a) Operation. The sum of the stresses in any component in a piping system due to pressure, weight, and other sustained loadings and of the stresses produced by occasional loads, such as wind and earthquake, shall not exceed the limits in the applicable part of para. A302.3.3. Wind and earthquake forces need not be considered as acting concurrently.

(b) Test. Stresses due to test conditions are not subject to the limitations in para. A302.3.3. It is not necessary to consider other occasional loads, such as wind and earthquake, as occurring concurrently with test loads.

A302.4 Allowances

Paragraph 302.4 applies in its entirety.

A01

PART 2
PRESSURE DESIGN OF PIPING COMPONENTS

A303 GENERAL

Paragraph 303 applies, except that references to Table A326.1 and para. A302.2.1 replace references to Table 326.1 and para. 302.2.1. For nonmetallic components, reference to para. A304 replaces reference to para. 304.

A304 PRESSURE DESIGN OF PIPING COMPONENTS A01

A304.1 Straight Pipe

A304.1.1 General

(a) The required thickness of straight sections of pipe shall be determined by Eq. (25).

$$t_m = t + c \tag{25}$$

The minimum thickness T for the pipe selected, considering manufacturer's minus tolerance, shall be not less than t_m.

(b) The following nomenclature is used in the equations for pressure design of straight pipe.

t_m = minimum required thickness, including mechanical, corrosion, and erosion allowances

t = pressure design thickness, as calculated in accordance with para. A304.1.2 for internal pressure or as determined in accordance with para. A304.1.3 for external pressure

c = the sum of mechanical allowances (thread or groove depth) plus corrosion and erosion allowance. For threaded components, the nominal thread depth (dimension h of ASME B1.20.1 or equivalent) shall apply. For machined surfaces or grooves where the tolerance is not specified, the tolerance shall be assumed to be 0.5 mm (0.02 in.) in addition to the specified depth of the cut.

T = pipe wall thickness (measured or minimum per purchase specification)

F = service (design) factor. See para. A302.3.2(c).

P = internal design gage pressure

D = outside diameter of pipe

S = design stress from applicable Table in Appendix B

A304.1.2 Straight Pipe Under Internal Pressure. The internal pressure design thickness t shall be not less than that calculated by one of the following equations, using stress values listed in or derived from the appropriate table in Appendix B.

(a) Thermoplastic Pipe [See Para. A302.3.2(a)]

$$t = \frac{PD}{2S + P} \text{ (Table B-1)} \tag{26a}$$

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:09 2005

(b) RTR (Laminated) Pipe [See Para. A302.3.2(b)]

$$t = \frac{PD}{2S + P} \text{(Table B-2)} \qquad (26b)^3$$

(c) RTR (Filament Wound) and RPM (Centrifugally Cast) Pipe [See Para. A302.3.2(c)]

$$t = \frac{PD}{2SF + P} \text{(Table B-3)} \qquad (26c)^3$$

A304.1.3 Straight Pipe Under External Pressure

(a) Nonmetallic Pipe. The external pressure design thickness t shall be qualified as required by para. A304.7.2.

(b) Metallic Pipe Lined With Nonmetals

(1) The external pressure design thickness t for the base (outer) material shall be determined in accordance with para. 304.1.3.

(2) The external pressure design thickness t for the lining material shall be qualified as required by para. A304.7.2.

A304.2 Curved and Mitered Segments of Pipe

A304.2.1 Pipe Bends. The minimum required thickness t_m of a bend, after bending, shall be determined as for straight pipe in accordance with para. A304.1.

A304.2.2 Elbows. Manufactured elbows not in accordance with para. A303 shall be qualified as required by para. A304.7.2.

A304.2.3 Miter Bends. Miter bends shall be qualified as required by para. A304.7.2.

A304.3 Branch Connections

A304.3.1 General. A pipe having a branch connection is weakened by the opening that must be made in it and, unless the wall thickness of the pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide added reinforcement. The amount of reinforcement shall be qualified as required by para. A304.7.2 except as provided in para. A304.3.2.

A304.3.2 Branch Connections Using Fittings. It may be assumed without calculation that a branch connection has adequate strength to sustain the internal and external pressure which will be applied to it if it utilizes a fitting (a tee, lateral, or cross) in accordance with para. A303.

A304.3.3 Additional Design Considerations. The requirements of paras. A304.3.1 and A304.3.2 are intended to assure satisfactory performance of a branch connection subjected only to internal or external pressure. The designer shall also consider paras. 304.3.5(a), (c), and (d).

A304.4 Closures

Closures not in accordance with para. A303 shall be qualified as required by para. A304.7.2.

A304.5 Pressure Design of Flanges

A304.5.1 General

(a) Flanges not in accordance with para. A303 or A304.5.1(b) or (c) shall be qualified as required by para. A304.7.2.

(b) Flanges for use with flat ring gaskets may be designed in accordance with BPV Code, Section VIII, Division 1, Appendix 2, except that the allowable stresses and temperature limits of this Code shall govern. Nomenclature shall be as defined in the BPV Code, except for the following:

P = design gage pressure
S_a = bolt design stress at atmospheric temperature[4]
S_b = bolt design stress at design temperature[4]
S_f = allowable stress for flange material from Table B-1, B-2, or B-3

(c) The flange design rules in para. A304.5.1(b) are not applicable to designs employing full face gaskets which extend beyond the bolts, usually to the outside diameter of the flange, or whose flanges are in solid contact beyond the bolts. The forces and reactions in such a joint differ from those joints employing flat ring gaskets, and the flange should be designed in accordance with BPV Code, Section VIII, Division 1, Appendix Y.

A304.5.2 Blind Flanges. Blind flanges not in accordance with para. A303 may be designed in accordance with para. 304.5.2, except that allowable stress S shall be taken from Tables in Appendix B. Otherwise, they shall be qualified as required by para. A304.7.2.

[3] The internal design pressure thickness t shall not include any thickness of the pipe wall reinforced with less than 20% by weight of reinforcing fibers.

[4] Bolt design stresses shall not exceed those in Table A-2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:09 2005

A304.6 Reducers

Reducers not in accordance with para. A303 shall be qualified as required by para. A304.7.2.

A304.7 Pressure Design of Other Components

A304.7.1 Listed Components. Other pressure containing components, manufactured in accordance with standards in Table A326.1 but not covered elsewhere in para. A304, may be utilized in accordance with para. A303.

A304.7.2 Unlisted Components and Elements. Pressure design of unlisted components and joints, to which the rules elsewhere in para. A304 do not apply, shall be based on calculations consistent with the design criteria of this Code. Calculations shall be substantiated by one or both of the means stated in (a) and (b) below, considering applicable ambient and dynamic effects in paras. 301.4 through 301.11:

(a) extensive, successful service experience under comparable design conditions with similarly proportioned components made of the same or like material;

(b) performance test under design conditions including applicable dynamic and creep effects, continued for a time period sufficient to determine the acceptability of the component or joint for its design life;

(c) for (a) or (b) above, the designer may interpolate between sizes, wall thicknesses, and pressure classes, and may determine analogies among related materials.

A304.7.3 Nonmetallic Components With Metallic Pressure Parts. Components not covered by standards in Table A326.1, in which both nonmetallic and metallic parts contain the pressure, shall be evaluated by applicable requirements of para. 304.7.2 as well as those of para. A304.7.2.

A01

PART 3
FLUID SERVICE REQUIREMENTS FOR PIPING COMPONENTS

A305 PIPE

Listed nonmetallic pipe may be used in Normal Fluid Service, subject to the limitations of the pressure-containing material and para. A323.4. Unlisted pipe may be used only in accordance with para. A302.2.3.

A306 NONMETALLIC FITTINGS, BENDS, MITERS, LAPS, AND BRANCH CONNECTIONS

General. Fittings, bends, miters, laps, and branch connections may be used in accordance with paras. A306.1 through A306.5. Pipe and other materials used in such components shall be suitable for the manufacturing process and the fluid service.

A306.1 Pipe Fittings

A306.1.1 Listed Fittings. Listed fittings may be used in Normal Fluid Service subject to limitations on materials.

A306.1.2 Unlisted Fittings. Unlisted fittings may be used only in accordance with para. A302.2.3.

A306.2 Pipe Bends

A306.2.1 General. A bend made in accordance with para. A332 and verified for pressure design in accordance with para. A304.2.1 shall be suitable for the same service as the pipe from which it is made.

A306.2.2 Corrugated and Other Bends. Bends of other designs (such as creased or corrugated) shall be qualified for pressure design as required by para. A304.7.2.

A306.3 Miter Bends

Except as specified in para. 306.3.2, a miter bend which conforms to para. A304.2.3 may be used in Normal Fluid Service.

A306.4 Fabricated or Flared Laps

The following requirements do not apply to fittings conforming to para. A306.1.

A306.4.1 Fabricated Laps

(a) The requirements in paras. 306.4.1(a) and (b) shall be met.

(b) Lap material shall be suitable for the service conditions. Pressure design shall be qualified as required by para. A304.7.2.

A306.4.2 Flared Laps. Flared laps shall not be used in nonmetallic piping.

A306.5 Fabricated Branch Connections

The following requirements do not apply to fittings conforming to para. A306.1.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:09 2005

A306.5.1 General. A fabricated branch connection made by bonding the branch pipe directly to the header pipe, with or without added reinforcement as stated in para. 328.5.4, and shown in Fig. 328.5.4, may be used in Normal Fluid Service, provided that pressure design is qualified as required by para. A304.7.2.

A306.5.2 Specific Requirements. Fabricated branch connections shall be made as specified in para. A328.5.

A307 NONMETALLIC VALVES AND SPECIALTY COMPONENTS

Paragraph 307 applies in its entirety, except that in para. 307.1.2 reference to paras. A302.2.3 and A304.7.2 replaces reference to paras. 302.2.3 and 304.7.2, respectively.

A308 FLANGES, BLANKS, FLANGE FACINGS, AND GASKETS

A308.1 General

Paragraph 308.1 applies, except that in para. 308.1.2 reference to para. A302.2.3 replaces reference to para. 302.2.3.

A308.2 Nonmetallic Flanges

A308.2.1 General

(a) Nonmetallic flanges shall be adequate, with suitable facing, gasketing, and bolting, to develop the full rating of the joint and to withstand expected external loadings.

(b) The designer should consult the manufacturer for ratings of nonmetallic flanges.

A308.2.2 Threaded Flanges. Threaded flanges are subject to the requirements for threaded joints in para. A314.

A308.3 Flange Facings

Paragraph 308.3 applies in its entirety.

A308.4 Limitations on Gaskets

See also Appendix F, para. F308.4.

A308.4.1 Lining Used as Facing or Gasket. Lining material extended over the flange face and used as a gasket shall conform to para. 308.4.

A309 BOLTING

Bolting includes bolts, bolt studs, studs, cap screws, nuts, and washers. See Appendix F, para. F309.

A309.1 General

Paragraph 309.1 applies in its entirety.

A309.2 Specific Bolting

Any bolting which meets the requirements of para. 309.1 may be used with any combination of flange materials and flange facings. Joint assembly shall conform to the requirements of para. A335.2.

A309.3 Tapped Holes in Nonmetallic Components

Tapped holes for pressure retaining bolting in nonmetallic piping components may be used provided pressure design is qualified as required by para. A304.7.2.

PART 4 A01
FLUID SERVICE REQUIREMENTS FOR PIPING JOINTS

A310 GENERAL

Paragraph 310 applies in its entirety.

A311 BONDED JOINTS IN PLASTICS

A311.1 General

Bonding shall be in accordance with para. A328 and examination shall be in accordance with para. A341.4.1 for use in Normal Fluid Service, subject to the limitations of the material.

A311.2 Specific Requirements

A311.2.1 Fillet Bonds. A fillet bond may be used only in conjunction with a qualified hot gas welding procedure for bonding (see para. A328.5.2).

A311.2.2 Seal Bonds. A seal bond may be used only to prevent leakage of a threaded joint and only if it has been demonstrated that there will be no deleterious effect on the materials bonded.

PART 8
PIPING COMPONENTS, STANDARDS

A326 DIMENSIONS AND RATINGS OF COMPONENTS

A326.1 Requirements

Paragraph 326 applies in its entirety except that references to Table A326.1 and Appendix B replace references to Table 326.1 and Appendix A, respectively.

A00 **A326.4 Abbreviations in Table A326.1 and Appendix B**

The abbreviations tabulated below are used in this Chapter to replace lengthy phrases in the text and in the titles of standards in Table A326.1 and the Specifications Index for Appendix B. Those marked with an asterisk (*) are in accordance with ASTM D 1600, Terminology Relating to Abbreviations, Acronyms, and Codes for Terms Relating to Plastics.

Abbreviation	Term
*ABS	Acrylonitrile-Butadiene-Styrene
*CAB	Cellulose Acetate-Butyrate
CP	Chlorinated Polyether
*CPVC	Chlorinated Poly (Vinyl Chloride)
ECTFE	Ethylene-Chlorotrifluoroethylene
ETFE	Ethylene-Tetrafluoroethylene
*FEP	Perfluoro (Ethylene-Propylene) copolymer
PB	Polybutylene
*PE	Polyethylene
PFA	Perfluoro (Alkoxyalkane) copolymer
*POM	Polyacetal, Poly (Oxymethylene)
POP	Poly (Phenylene Oxide)
*PP	Polypropylene
*PPS	Poly (Phenylene Sulfide)
PR	Pressure Rated
*PTFE	Polytetrafluoroethylene
*PVC	Poly (Vinyl Chloride)
*PVDC	Poly (Vinylidene Chloride)
*PVDF	Poly (Vinylidene Fluoride)
RPM	Reinforced Plastic Mortar
RTR	Reinforced Thermosetting Resin
SDR	Standard Dimensional Ratio

PART 9
FABRICATION, ASSEMBLY, AND ERECTION

A327 GENERAL

Piping materials and components are prepared for assembly and erection by one or more of the fabrication processes in paras. A328, A329, A332, and A334. When any of these processes is used in assembly and erection, requirements are the same as for fabrication.

A328 BONDING OF PLASTICS

Paragraph A328 applies only to joints in thermoplastic, RTR, and RPM piping. Bonding shall conform to paras. A328.1 through A328.7 and the applicable requirements of para. A311.

A328.1 Bonding Responsibility

Each employer is responsible for the bonding done by personnel of his organization and, except as provided in paras. A328.2.2 and A328.2.3, shall conduct the required performance qualification tests to qualify bonding procedure specifications (BPS) and bonders or bonding operators.

A328.2 Bonding Qualifications

A328.2.1 Qualification Requirements

(a) Qualification of the BPS to be used, and of the performance of bonders and bonding operators, is required. To qualify a BPS, all tests and examinations specified therein and in para. A328.2.5 shall be completed successfully.

(b) In addition to the procedure for making the bonds, the BPS shall specify at least the following:

(1) all materials and supplies (including storage requirements);

(2) tools and fixtures (including proper care and handling);

(3) environmental requirements (e.g., temperature, humidity, and methods of measurement);

(4) joint preparation;

(5) dimensional requirements and tolerances;

(6) cure time;

(7) protection of work;

(8) tests and examinations other than those required by para. A328.2.5; and

(9) acceptance criteria for the completed test assembly.

A328.2.2 Procedure Qualification by Others. Subject to the specific approval of the Inspector, a BPS qualified by others may be used provided that:

(a) the Inspector satisfies himself that the proposed qualified BPS has been prepared and executed by a responsible recognized organization with expertise in the field of bonding;

NOTES:
(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.
(2) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.
(3) The term *fiberglass RTR* takes the place of the ASTM designation: "*fiberglass*" (*glass-fiber-reinforced thermosetting resin*).
(4) This Standard allows the use of unlisted materials; see para. 323.1.2.
(5) This Standard contains no pressure-temperature ratings.

Wed Feb 02 00:57:11 2005

(b) by signature, the employer accepts both the BPS and procedure qualification record (PQR) as his own; and

(c) the employer has at least one currently employed bonder who, while in his employ, has satisfactorily passed a performance qualification test using the proposed qualified BPS.

A328.2.3 Performance Qualification by Others. Without the Inspector's specific approval, an employer shall not accept a performance qualification test made by a bonder or bonding operator for another employer. If approval is given, it is limited to work on piping using the same or equivalent BPS. An employer accepting such performance qualification tests shall obtain a copy of the performance qualification test record from the previous employer showing the name of the employer by whom the bonder or bonding operator was qualified, the date of such qualification, and the date the bonder or bonding operator last bonded pressure piping under such performance qualification.

A328.2.4 Qualification Records. The employer shall maintain a self-certified record, available to the owner or owner's agent and to the Inspector, of the BPS used and the bonders or bonding operators employed by him, and showing the dates and results of BPS qualifications and bonding performance qualifications.

A328.2.5 Qualification Tests. Tests, as specified in para. A328.2.1(a), shall be performed to qualify each BPS and the performance of each bonder and bonding operator. Test assemblies shall conform to (a) below and the test method shall be in accordance with either (b) or (c).

A01 *(a) Test Assembly.* The assembly shall be fabricated in one pipe size in accordance with the BPS and shall contain at least one of each different type of joint identified in the BPS. More than one test assembly may be prepared if necessary to accommodate all of the joint types or to assure that at least one of each joint type is loaded in both circumferential and longitudinal directions. The size of pipe and fittings in the assembly shall be as follows.

(1) When the largest size to be joined is DN 100 (NPS 4) or smaller, the test assembly shall be the largest size to be joined.

(2) When the largest size to be joined is greater than DN 100 (NPS 4), the size of the test assembly shall be between 25% and 100% of the largest piping size to be joined, but shall be a minimum of DN 100 (NPS 4).

(b) Burst Test Method. The test assembly shall be subjected to a burst test in accordance with the applicable sections of ASTM D 1599.[5] The time to burst in this standard may be extended. The test is successful if failure initiates outside of any bonded joint.

(c) Hydrostatic Test Method. The test assembly shall be subjected to hydrostatic pressure of at least P_T for not less than 1 hr with no leakage or separation of joints.

(1) For thermoplastics, P_T shall be determined in accordance with Eq. (27):

$$P_T = 0.80\overline{T}\left(\frac{(S_S + S_H)}{D - \overline{T}}\right) \quad (27)$$

where

D = outside diameter of pipe
$\overline{T}$ = nominal thickness of pipe
S_S = mean short term burst stress in accordance with ASTM D 1599,[5] from Table B-1 if listed, otherwise from manufacturer's data.
S_H = mean long term hydrostatic strength (LTHS) in accordance with ASTM D 2837. Use twice the 23°C (73°F) HDB design stress from Table B-1 if listed; or use manufacturer's data.

(2) For RTR (laminated and filament-wound) and RPM, P_T shall be three times the manufacturer's allowable pressure for the components being joined.

(3) The test shall be conducted so that the joint is loaded in both the circumferential and longitudinal directions.

A328.2.6 Performance Requalification. Renewal of a bonding performance qualification is required when:

(a) a bonder or bonding operator has not used the specific bonding process for a period of 6 months or more; or (99) A00

(b) there is specific reason to question the individual's ability to make bonds that meet the BPS.

A328.3 Bonding Materials and Equipment

A328.3.1 Materials. Bonding materials that have deteriorated by exposure to air or prolonged storage, or will not spread smoothly, shall not be used in making joints.

A328.3.2 Equipment. Fixtures and tools used in making joints shall be in such condition as to perform their functions satisfactorily.

[5] Titles of referenced standards and specifications are listed in Table A326.1, except ASTM D 1599 and ASTM D 2855, Practice for Making Solvent-Cemented Joints with PVC Pipe and Fittings.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:11 2005

A328.4 Preparation for Bonding

Preparation shall be defined in the BPS and shall specify such requirements as:

(a) cutting;
(b) cleaning;
(c) preheat;
(d) end preparation; and
(e) fit-up.

(99) ### A328.5 Bonding Requirements

A328.5.1 General

(a) Production joints shall be made only in accordance with a written bonding procedure specification (BPS) that has been qualified in accordance with para. A328.2. Manufacturers of piping materials, bonding materials, and bonding equipment should be consulted in the preparation of the BPS.

(b) Production joints shall be made only by qualified bonders or bonding operators who have appropriate training or experience in the use of the applicable BPS and have satisfactorily passed a performance qualification test that was performed in accordance with a qualified BPS.

(c) Each qualified bonder and bonding operator shall be assigned an identification symbol. Unless otherwise specified in the engineering design, each pressure containing bond or adjacent area shall be stenciled or otherwise suitably marked with the identification symbol of the bonder or bonding operator. Identification stamping shall not be used and any marking paint or ink shall not be detrimental to the piping material. In lieu of marking the bond, appropriate records may be filed.

(d) Qualification in one BPS does not qualify a bonder or bonding operator for any other bonding procedure.

(e) Longitudinal joints are not covered in para. A328.

A328.5.2 Hot Gas Welded Joints in Thermoplastic Piping[5]

(a) Preparation. Surfaces to be hot gas welded together shall be cleaned of any foreign material. For butt welds, the joining edges should be beveled at 20 deg to 40 deg with 1 mm ($^1/_{32}$ in.) root face and root gap.

(b) Procedure. Joints shall be made in accordance with the qualified BPS.

(c) Branch Connections. A fabricated branch connection shall be made by inserting the branch pipe in the hole in the run pipe. Dimensions of the joint shall conform to Fig. 328.4.4 sketch (c). The hole in the run pipe shall be beveled at 45 deg. Alternatively, a fabricated branch connection shall be made using a manufactured full reinforcement saddle with integral socket.

A328.5.3 Solvent Cemented Joints in Thermoplastic Piping[5]

(a) Preparation. PVC and CPVC surfaces to be solvent cemented shall be cleaned by wiping with a clean cloth moistened with acetone or methylethyl ketone. Cleaning for ABS shall conform to ASTM D 2235. A slight interference fit between pipe and fitting socket is preferred and diametral clearance between pipe and entrance of fitting socket shall not exceed 1.0 mm (0.04 in.). This fit shall be checked before solvent cementing.

(b) Procedure. Joints shall be made in accordance with the qualified BPS. ASTM D 2855 provides a suitable basis for development of such a procedure. Solvent cements for PVC, CPVC, and ABS shall conform to ASTM D 2564, D 2846, and D 2235, respectively. Application of cement to both surfaces to be joined and assembly of these surfaces shall produce a continuous bond between them with visual evidence of cement at least flush with the outer end of the fitting bore around the entire joint perimeter. See Fig. A328.5.3.

(c) Branch Connections. A fabricated branch connection shall be made using a manufactured full reinforcement saddle with integral branch socket. The reinforcement saddle shall be solvent cemented to the run pipe over its entire contact surface.

A328.5.4 Heat Fusion Joints in Thermoplastic Piping[5]

(a) Preparation. Surfaces to be heat fused together shall be cleaned of all foreign material.

(b) Procedure. Joints shall be made in accordance with the qualified BPS. The general procedures in ASTM D 2657, Techniques I — Socket Fusion, II — Butt Fusion, and III — Saddle Fusion, provide a suitable basis for development of such a procedure. Uniform heating of both surfaces to be joined and assembly of these surfaces shall produce a continuous homogeneous bond between them and shall produce a small fillet of fused material at the outer limits of the joint. See Fig. A328.5.4 for typical heat fusion joints. Fixtures shall be used to align components when joints are made. A01

(c) Branch Connections. A fabricated branch connection is permitted only where molded fittings are unavailable.

Wed Feb 02 00:57:11 2005

A328.5.5 Electrofusion Joints in Thermoplastic Piping

(a) Preparation. Surfaces to be heat fused together shall be cleaned of all foreign material.

(b) Procedure. Joints shall be made in accordance with the qualified BPS. The general procedures in ASTM F 1290, Technique I — Coupling Procedure and Technique II — Saddle Procedure provide a suitable basis for the development of such a procedure. See Fig. A328.5.5.

A328.5.6 Adhesive Joints in RTR and RPM Piping

(a) Procedure. Joints shall be made in accordance with the qualified BPS. Application of adhesive to the surfaces to be joined and assembly of these surfaces shall produce a continuous bond between them and shall seal over all cuts to protect the reinforcement from the service fluid. See Fig. A328.5.6.

(b) Branch Connections. A fabricated branch connection shall be made using a manufactured full reinforcement saddle having a socket or integral length of branch pipe suitable for a nozzle or coupling. The hole in the run pipe shall be made with a hole saw; the cut edges of the hole shall be sealed with adhesive at the time the saddle is bonded to the run pipe.

A328.5.7 Butt-and-Wrapped Joints in RTR and RPM Piping[5]

(a) Procedure. Joints shall be made in accordance with the qualified BPS. Application of plies of reinforcement saturated with catalyzed resin to the surfaces to be joined shall produce a continuous structure with them. Cuts shall be sealed to protect the reinforcement from the service fluid. See Fig. A328.5.7.

(b) Branch Connections. For a fabricated branch connection made by inserting the branch pipe into a hole in the run pipe, the hole shall be made with a hole saw.

A328.6 Bonding Repair

Defective material, joints, and other workmanship that fails to meet the requirements of this Code and of the engineering design shall be repaired or replaced. See also para. 341.3.3.

A328.7 Seal Bonds

If threaded joints are to be seal bonded in accordance with para. A311.2.2, the work shall be done by qualified bonders and all exposed threads shall be covered by the seal bond.

A329 FABRICATION OF PIPING LINED WITH NONMETALS

A329.1 Welding of Metallic Piping

A329.1.1 General

(a) Paragraph A329.1 applies only to welding subassemblies of metallic piping that have previously been lined with nonmetals.

(b) Welding which conforms to para. A329.1 may be used in accordance with para. A318.3.1.

A329.1.2 Specific Welding Requirements. Welding shall conform to the requirements of para. 328 and the following additional requirements.

(a) Modifications made in preparation for welding to suit manufacturer's recommendations shall be specified in the engineering design.

(b) Welding shall be performed so as to maintain the continuity of the lining and its serviceability.

(c) If a lining has been damaged, it shall be repaired or replaced.

(d) Qualification to one WPS for a specific lining material does not qualify a welder or welding operator for any other welding procedure involving different lining materials.

A329.2 Flaring of Nonmetallic Linings

A329.2.1 General

(a) Paragraph A329.2 applies only to the flaring of linings in pipe that has previously been lined with nonmetals.

(b) Flaring which conforms to para. A329.2 may be used in accordance with para. A318.3.2.

(c) Flaring shall be performed only in accordance with a written flaring procedure specification, and only by qualified operators who have appropriate training or experience in the use of the applicable flaring procedure specification.

A332 BENDING AND FORMING

A332.1 General

Paragraph 332.1 applies in its entirety.

A332.2 Bending

Paragraph 332.2 applies, except para. 332.2.2.

A332.3 Forming

Paragraph 332.3 applies, except for heat treatment.

A334 JOINING NONPLASTIC PIPING

A334.1 Borosilicate Glass Piping

Short unflanged pieces used to correct for differences between fabrication drawings and field dimensions may be cut to length and finished in the field.

A334.2 Repair of Defects

Defective material, joints, and other workmanship in nonplastic piping that fail to meet the requirements of para. A334 or of the engineering design shall be repaired or replaced.

Completed repairs and replacements shall be examined, subject to the same limitations on imperfections as the original work.

A335 ASSEMBLY AND ERECTION

A335.1 General

Paragraph 335.1.1 applies in its entirety.

A335.2 Flanged and Mechanical Joints

Paragraph 335.2 applies in its entirety.

A335.2.5 Nonmetallic Bolted Joints

(a) Bolted joints in nonmetallic piping may be assembled with any combination of flange material and flange facings, except that when other than flat face flanges and full face gaskets are used:

(1) consideration shall be given to the strength of the flanges, and to sustained loads, displacement strains, and occasional loads described in paras. A302.3.4 and A302.3.5; and

(2) an appropriate bolt-up sequence shall be specified.

(b) Appropriate limits shall be specified for bolt-up torque, and those limits shall not be exceeded.

(c) Flat washers shall be used under bolt heads and nuts.

A335.2.6 Metallic Piping Lined With Nonmetals. In assembling mechanical joints in metallic piping lined with nonmetals, consideration shall be given to means for maintaining electrical continuity between pipe sections, where static sparking could cause ignition of flammable vapors. See Appendix F, para. FA323.4(a).

A335.3 Threaded Joints

Paragraph 335.3 applies except for para. 335.3.2. See para. A335.3.2.

A335.3.2 Joints for Seal Bonding. A threaded joint to be seal bonded shall be made up without thread compound. A joint containing thread compound which leaks during leak testing may be seal bonded in accordance with para. A328.6, provided all compound is removed from exposed threads.

A335.3.4 General, Nonmetallic Piping. Either strap wrenches or other full circumference wrenches shall be used to tighten threaded pipe joints. Tools and other devices used to hold or apply forces to the pipe shall be such that the pipe surface is not scored or deeply scratched.

A335.3.5 RTR and RPM Piping. In assembling threaded joints in RTR and RPM piping, where threads may be exposed to fluids which can attack the reinforcing material, threads shall be coated with sufficient resin to cover the threads and completely fill the clearance between the pipe and the fitting.

A335.4 Tubing Joints

A335.4.1 Flared Joints in Thermoplastic Tubing. In addition to preparation in accordance with para. 335.4.1, flared joints shall be made in accordance with ASTM D 3140, Flared Joints for Polyolefins.

A335.4.2 Flareless and Compression Tubing Joints. Paragraph 335.4.2 applies.

A335.5 Caulked Joints

Paragraph 335.5 applies.

A335.6 Special Joints

Paragraph 335.6 applies, except that expanded joints are not permitted.

A335.6.3 Flexible Elastomeric Sealed Joints. Assembly of flexible elastomeric sealed joints shall be in accordance with the manufacturer's recommendations and the following.

(a) Seal and bearing surfaces shall be free from injurious imperfections.

(b) Any lubricant used to facilitate joint assembly shall be compatible with the joint components and the intended service.

(c) Proper joint clearances and piping restraints (if not integral in the joint design) shall be provided to

K302.2.5 Ratings at Junction of Different Services. Paragraph 302.2.5 applies.

K302.3 Allowable Stresses and Other Design Limits

K302.3.1 General. The allowable stresses defined below shall be used in design calculations unless modified by other provisions of this Chapter.

(a) Tension. Allowable stresses in tension for use in design in accordance with this Chapter are listed in Table K-1, except that maximum allowable stress values and design stress intensity values for bolting, respectively, are listed in the BPV Code, Section II, Part D, Tables 3 and 4.

The tabulated stress values in Table K-1 are grouped by materials and product form and are for stated temperatures up to the limit provided for the materials in para. K323.2.1. Straight line interpolation between temperatures to determine the allowable stress for a specific design temperature is permissible. Extrapolation is not permitted.

(b) Shear and Bearing. Allowable stress in shear shall be 0.80 times the allowable stress in tension tabulated in Table K-1. Allowable stress in bearing shall be 1.60 times the allowable stress in tension.

(c) Compression. Allowable stress in compression shall be no greater than the allowable stress in tension tabulated in Table K-1. Consideration shall be given to structural stability.

(d) Fatigue. Allowable values of stress amplitude, which are plotted as a function of design life in the BVP Code, Section VIII, Division 2, Appendix 5, may be used in fatigue analysis in accordance with para. K304.8.

A01 **K302.3.2 Bases for Allowable Stresses.** The bases for establishing allowable stress values for materials in this Chapter are as follows.

(99) *(a) Bolting Materials.* The criteria of Section II, Part D, Appendix 2, para. 2-120 or 2-130, or Section VIII, Division 3, Article KD-6, para. KD-620, as applicable, apply.

(b) Other Materials. For materials other than bolting materials, the following rules apply.

(1) Except as provided in (b)(2) below, allowable stress values at design temperature for materials listed in Section II, Part D shall not exceed the lower of: two-thirds of the specified minimum yield strength at room temperature (SMYS), and two-thirds of the yield strength at temperature.

(2) For solution heat treated austenitic stainless steels and certain nickel alloys with similar stress-strain behavior, allowable stress values shall not exceed the lower of: two-thirds of the SMYS, and 90% of the yield strength at temperature.

(3) Allowable stresses for materials which are not listed in Section II, Part D shall not exceed the following:

(a) Temperatures not exceeding 100°F. Two-thirds of the SMYS.

(b) Temperatures exceeding 100°F. The corresponding values listed in Table A-1 (see para. 302.3.2).

Application of stress values so determined is not recommended for flanged joints and other components in which slight deformation can cause leakage or malfunction. [These values are shown in *italics* or **boldface** in Table K-1, as explained in Note (5) to Appendix K Tables.] Instead, either 75% of the stress value in Table K-1 or two-thirds of the yield strength at temperature listed in Section II, Part D, Table Y-1 should be used.

(c) Unlisted Materials. For a material which conforms to para. K323.1.2, the yield strength at temperature shall be derived by multiplying the average expected yield strength at temperature by the SMYS divided by the average expected yield strength at room temperature.

(d) Cyclic Stresses. Allowable values of alternating stress shall be in accordance with Section VIII, Division 2, Appendices 4 and 5.

K302.3.3 Casting Quality Factor.[1] The casting quality factor E_c shall be 1.00 by conformance to all of the following supplementary requirements.

(a) All surfaces shall have a surface finish not rougher than 6.3 μm R_a (250 μin. R_a per ASME B46.1).

(b) All surfaces shall be examined by either the liquid penetrant method in accordance with ASTM E 165, or the magnetic particle method in accordance with ASTM E 709. Acceptability of imperfections and weld repairs shall be judged in accordance with MSS SP-53, using ASTM E 125 as reference.

(c) Each casting shall be fully examined either ultrasonically in accordance with ASTM E 114, or radiographically in accordance with ASTM E 142. Cracks and hot tears (Category D and E discontinuities per the standards listed in Table K302.3.3D) and imperfections whose depth exceeds 3% of nominal wall thickness

[1] See Notes to Tables 302.3.3C and 302.3.3D for titles of standards referenced herein.

Copyright by the American Society Of Mechanical Engineers

TABLE K302.3.3D
ACCEPTABLE SEVERITY LEVELS FOR STEEL CASTINGS

Thickness Examined, mm (in.)	Applicable Standards	Acceptable Severity Level	Acceptable Discontinuity Categories
$\overline{T} \le 51$ (2)	ASTM E 446	1	A, B, C
$51 < \overline{T} \le 114$ (4.5)	ASTM E 186	1	A, B, C
$114 < \overline{T} \le 305$ (12)	ASTM E 280	1	A, B, C

are not permitted. Acceptable severity levels for radiographic examination of castings shall be in accordance with Table K302.3.3D.

K302.3.4 Weld Joint Quality Factor. Piping components containing welds shall have a weld joint quality factor $E_j = 1.00$ (see Table 302.3.4 for requirements) except that the acceptance criteria for these welds shall be in accordance with para. K341.3.2. Spiral welds are not permitted.

K302.3.5 Limits of Calculated Stresses Due to Sustained Loads and Displacement Strains

(a) Internal Pressure Stresses. Stresses due to internal pressure shall be considered safe when the wall thickness of the piping component, and its means of stiffening, meet the requirements of para. K304.

(b) External Pressure Stresses. Stresses due to external pressure shall be considered safe when the wall thickness of the piping component, and its means of stiffening, meet the requirements of para. K304.

(c) Longitudinal Stresses S_L. The sum of longitudinal stresses in any component in a piping system, due to pressure, weight, and other sustained loadings S_L shall not exceed S_h in (d) below. The thickness of pipe used in calculating S_L shall be the nominal thickness minus mechanical, corrosion, and erosion allowance c.

(d) Allowable Displacement Stress Range S_A. The computed displacement stress range S_E in a piping system (see para. 319.4.4) shall not exceed the allowable displacement stress range S_A (see para. 319.2.3) calculated by

$$S_A = 1.25S_c + 0.25S_h \quad (32)$$

In the above equation,

S_c = allowable stress from Table K-1 at minimum metal temperature expected during the displacement cycle under analysis

S_h = allowable stress from Table K-1 at maximum metal temperature expected during the displacement cycle under analysis

K302.3.6 Limits of Calculated Stresses Due to Occasional Loads

(a) Operation. The sum of the longitudinal stresses due to pressure, weight, and other sustained loadings S_L, and of the stresses produced by occasional loads such as wind or earthquake, may be as much as 1.2 times the allowable stress given in Table K-1. Wind and earthquake forces need not be considered as acting concurrently.

(b) Test. Stresses due to test conditions are not subject to the limitations in para. K302.3. It is not necessary to consider other occasional loads, such as wind and earthquake, as occurring concurrently with test loads.

K302.4 Allowances

In determining the minimum required thickness of a piping component, allowances shall be included for corrosion, erosion, and thread or groove depth. See the definition of c in para. K304.1.1(b).

K302.4.1 Mechanical Strength. Paragraph 302.4.1 applies. In addition, a fatigue analysis in accordance with para. K304.8 shall be performed for any means used to increase the strength of a piping component.

PART 2
PRESSURE DESIGN OF PIPING COMPONENTS

K303 GENERAL

Components manufactured in accordance with standards listed in Table K326.1 shall be considered suitable for use at pressure-temperature ratings in accordance with para. K302.2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:13 2005

K304 PRESSURE DESIGN OF HIGH PRESSURE COMPONENTS

K304.1 Straight Pipe

K304.1.1 General

(a) The required wall thickness of straight sections of pipe shall be determined in accordance with Eq. (33).

$$t_m = t + c \tag{33}$$

The minimum wall thickness T for the pipe selected, considering manufacturer's minus tolerance, shall be not less than t_m.

A01 *(b)* The following nomenclature is used in the equation for pressure design of straight pipe.

t_m = minimum required wall thickness, including mechanical, corrosion, and erosion allowances

t = pressure design wall thickness, as calculated in para. K304.1.2 for internal pressure, or in accordance with the procedure listed in para. K304.1.3 for external pressure

$c = c_I + c_o$

= the sum of mechanical allowances[2] (thread or groove depth) plus corrosion and erosion allowances (where c_I = the sum of *internal* allowances and c_o = the sum of *external* allowances). For threaded components, the nominal thread depth (dimension h of ASME B1.20.1 or equivalent) shall apply, except that for straight threaded connections, the external thread groove depth need not be considered provided:

(a) it does not exceed 20% of the wall thickness;

(b) the ratio of outside to inside diameter, D/d, is greater than 1.1;

(c) the internally threaded attachment provides adequate reinforcement; and

(d) the thread plus the undercut area, if any, does not extend beyond the reinforcement for a distance more than the nominal wall thickness of the pipe.

Adequate reinforcement by the attachment is defined as that necessary to ensure that the static burst pressure of the connection will equal or exceed that of the unthreaded portion of the pipe. The adequacy of the reinforcement shall be substantiated as required by para. K304.7.2.

T = pipe wall thickness (measured or minimum per purchase specification)

P = internal design gage pressure

D = outside diameter of pipe. For design calculations in accordance with this Chapter, the outside diameter of the pipe is the maximum value allowable under the specifications.

d = inside diameter of pipe. For design calculations in accordance with this Chapter, the inside diameter of the pipe is the maximum value allowable under the specifications.

S = allowable stress from Table K-1

K304.1.2 Straight Pipe Under Internal Pressure. The internal pressure design wall thickness t shall be not less than that calculated in accordance with Eq. (34a) for pipe with a specified outside diameter and minimum wall thickness, or Eq. (34b) for pipe with a specified inside diameter and minimum wall thickness.

$$t = \frac{D - 2c_o}{2}\left[1 - \exp\left(\frac{-1.155P}{S}\right)\right] \tag{34a}^{3,4,5}$$

or

$$t = \frac{d + 2c_I}{2}\left[\exp\left(\frac{1.155P}{S}\right) - 1\right] \tag{34b}^{3,4,5}$$

Alternatively, the internal design gage pressure P may be calculated by Eq. (35a) or (35b).

$$P = \frac{S}{1.155}\ln\left[\frac{D - 2c_o}{D - 2(T - c_I)}\right] \tag{35a}^{4,5}$$

or

$$P = \frac{S}{1.155}\ln\left[\frac{d + 2(T - c_o)}{d + 2c_I}\right] \tag{35b}^{4,5}$$

[2] For machined surfaces or grooves where the tolerance is not specified, the tolerance shall be assumed to be 0.5 mm (0.02 in.) in addition to the specified depth of the cut.

[3] An exponential [e.g., the term exp $(-1.155P/S)$] represents the base of natural logarithms e raised to the stated power (i.e., $-1.155P/S$).

[4] The intent of this equation is to provide a factor of not less than 2.0 on the pressure required, according to the von Mises theory, to initiate yielding on the outside surface of a cylinder made from a perfect elastic-plastic material.

[5] Any mechanical, corrosion, or erosion allowance c not specified as internal c_I or external c_o shall be assumed to be internal, i.e., $c = c_I$ and $c_o = 0$.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:13 2005

K304.1.3 Straight Pipe Under External Pressure. The pressure design thickness for straight pipe under external pressure shall be determined in accordance with para. K304.1.2 for pipe where $D/t < 3.33$, if at least one end of the pipe is exposed to full external pressure, producing a compressive axial stress. For $D/t \geq 3.33$, and for $D/t < 3.33$ where external pressure is not applied to at least one end of the pipe, the pressure design wall thickness shall be determined in accordance with para. 304.1.3 except that the stress values shall be taken from Table K-1.

K304.2 Curved and Mitered Segments of Pipe

K304.2.1 Pipe Bends. The minimum required wall thickness t_m of a bend, after bending, may be determined as for straight pipe in accordance with para. K304.1, provided that the bend radius of the pipe center line is equal to or greater than ten times the nominal pipe outside diameter and the tolerances and strain limits of para. K332 are met. Otherwise the design shall be qualified as required by para. K304.7.2.

K304.2.2 Elbows. Manufactured elbows not in accordance with para. K303 and pipe bends not in accordance with para. K304.2.1 shall be qualified as required by para. K304.7.2.

K304.2.3 Miter Bends. Miter bends are not permitted.

K304.2.4 Curved Segments of Pipe Under External Pressure. The wall thickness of curved segments of pipe subjected to external pressure may be determined as specified for straight pipe in para. K304.1.3 provided the design length L is the running center line length between any two sections which are stiffened in accordance with para. 304.1.3.

K304.3 Branch Connections

K304.3.1 General. Acceptable branch connections include: a fitting in accordance with para. K303; an extruded outlet in accordance with para. 304.3.4; or a branch connection fitting (see para. 300.2) similar to that shown in Fig. K328.5.4.

K304.3.2 Strength of Branch Connections

(a) The opening made for a branch connection reduces both static and fatigue strength of the run pipe. There shall be sufficient material in the branch connection to contain pressure and meet reinforcement requirements.

(b) Static pressure design of a branch connection not in accordance with para. K303 shall conform to para. 304.3.4 for an extruded outlet or shall be qualified as required by para. K304.7.2.

K304.3.3 Reinforcement of Welded Branch Connections. Branch connections made as provided in para. 304.3.3 are not permitted.

K304.4 Closures

(a) Closures not in accordance with para. K303 or (b) below shall be qualified as required by para. K304.7.2.

(b) Closures may be designed in accordance with (99) the rules, allowable stresses, and temperature limits of the BPV Code, Section VIII, Division 2 or Division 3, and Section II, Part D.

K304.5 Pressure Design of Flanges and Blanks

K304.5.1 Flanges — General

(a) Flanges not in accordance with para. K303 or (b) below shall be qualified as required by para. K304.7.2.

(b) A flange may be designed in accordance with (99) the rules, allowable stresses, and temperature limits of Section VIII, Division 2, Appendix 3 (or Appendices 4, 5, and 6) or Division 3, Article KD-6, and Section II, Part D.

K304.5.2 Blind Flanges (99)

(a) Blind flanges not in accordance with para. K303 or (b) or (c) below shall be qualified as required by para. K304.7.2.

(b) A blind flange may be designed in accordance with Eq. (36). The thickness of the flange selected shall be not less than t_m (see para. K304.1.1 for nomenclature), considering manufacturing tolerance.

$$t_m = t + c \qquad (36)$$

The rules, allowable stresses, and temperature limits of Section VIII, Division 2, AD-700 may be used, with the following changes in nomenclature, to calculate t_m.

t = pressure design thickness (in place of T) as calculated for the given style of blind flange using the appropriate equation of AD-700.

c = sum of mechanical allowances, defined in para. K304.1.1.

(c) A blind flange may be designed in accordance with the rules, allowable stresses, and temperature limits of Section VIII, Division 3, Article KD-6 and Section II, Part D.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:14 2005

K304.5.3 Blanks. Design of blanks shall be in accordance with para. 304.5.3, except that E shall be 1.00 and the definitions of S and c shall be in accordance with para. K304.1.1.

K304.6 Reducers

Reducers not in accordance with para. K303 shall be qualified as required by para. K304.7.2.

K304.7 Pressure Design of Other Components

K304.7.1 Listed Components. Other pressure containing components manufactured in accordance with standards in Table K326.1 may be utilized in accordance with para. K303.

A01 **K304.7.2 Unlisted Components and Elements.** Static pressure design of unlisted components and other piping elements, to which the rules in paras. K304.1 through K304.6 do not apply, shall be based on calculations consistent with the design philosophy of this Chapter. These calculations shall be substantiated by one or more of the means stated in (a), (b), and (c) below, considering applicable ambient and dynamic effects in paras. 301.4 through 301.11:

(a) extensive, successful service experience under comparable design conditions with similarly proportioned components made of the same or like material;

(b) performance testing sufficient to substantiate both the static pressure design and fatigue life at the intended operating conditions. Static pressure design may be substantiated by demonstrating that failure or excessive plastic deformation does not occur at a pressure equivalent to two times the internal design pressure P. The test pressure shall be two times the design pressure multiplied by the ratio of allowable stress at test temperature to the allowable stress at design temperature, and by the ratio of actual yield strength to the specified minimum yield strength at room temperature from Table K-1;

(c) detailed stress analysis (e.g., finite element method) with results evaluated as described in Section VIII, Division 3, Article KD-2;

(d) for (a), (b), and (c) above, interpolations supported by analysis, are permitted between sizes, wall thicknesses, and pressure classes, as well as analogies among related materials with supporting material property data. Extrapolation is not permitted.

K304.7.3 Components With Nonmetallic Parts. Except for gaskets and packing, nonmetallic parts are not permitted.

K304.7.4 Bellows Type Expansion Joints. Bellows type expansion joints are not permitted.

K304.8 Fatigue Analysis

K304.8.1 General. A fatigue analysis shall be performed on each piping system, including all components[6] and joints therein, and considering the stresses resulting from attachments, to determine its suitability for the cyclic operating conditions[7] specified in the engineering design. Except as permitted in (a) and (b) below, or in paras. K304.8.5 and K304.8.6, this analysis shall be in accordance with the BPV Code, Section VIII, Division 2.[8] The cyclic conditions shall include pressure variations as well as thermal variations or displacement stresses. The requirements of para. K304.8 are in addition to the requirements for a flexibility analysis stated in para. K319. No formal fatigue analysis is required in systems that:

(a) are duplicates of successfully operating installations or replacements without significant change of systems with a satisfactory service record; or

(b) can readily be judged adequate by comparison with previously analyzed systems.

K304.8.2 Amplitude of Alternating Stress. The value of the alternating stress amplitude for comparison with design fatigue curves shall be determined in accordance with Section VIII, Division 2, Appendices 4 and 5.

K304.8.3 Allowable Amplitude of Alternating Stress. The allowable amplitude of alternating stress shall be determined from the applicable design fatigue curve in Section VIII, Division 2, Appendix 5. The designer is cautioned that the considerations listed in para. K302.1 may reduce the fatigue life of the component below the value predicted by that curve.

K304.8.4 Pressure Stress Evaluation for Fatigue Analysis

(a) For fatigue analysis of straight pipe, Eq. (37) may be used to calculate the stress intensity[9] at the

---

[6] Bore imperfections may reduce fatigue life.

[7] If the range of temperature change varies, equivalent full temperature cycles N may be computed as provided in footnote 6 to para. 302.3.5.

[8] Fatigue analysis in accordance with Section VIII, Division 2, requires that stress concentration factors be used in computing the cyclic stresses.

[9] The term "stress intensity" is defined in Section VIII, Division 2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:14 2005

inside surface due only to internal pressure.

$$S = \frac{PD^2}{2(T-c)[D-(T-c)]} \quad (37)$$

(b) For fatigue analysis of curved pipe, Eq. (37) may be used, with the dimensions of the straight pipe from which it was formed, to calculate the maximum stress intensity at the inside surface due only to internal pressure, provided that the center line bend radius is not less than ten times the nominal outside diameter of the pipe, and that the tolerance and strain limits of para. K332 are met. Bends of smaller radius shall be qualified as required by para. K304.7.2.

(c) If the value of S calculated by Eq. (37) exceeds three times the allowable stress from Table K-1 at the average temperature during the loading cycle, an inelastic analysis is required.

K304.8.5 Fatigue Evaluation by Test. With the owner's approval, the design fatigue life of a component may be established by destructive testing in accordance with para. K304.7.2 in lieu of the above analysis requirements.

K304.8.6 Extended Fatigue Life. The design fatigue life of piping components may be extended beyond that determined by the Section VIII, Division 2, Appendix 5 fatigue curves by the use of one of the methods listed below, provided that the component is qualified in accordance with para. K304.7.2:

(a) surface treatments, such as improved surface finish; and

(b) prestressing methods, such as autofrettage, shot peening, or shrink fit.

The designer is cautioned that the benefits of prestress may be reduced due to thermal, strain softening, or other effects.

PART 3
FLUID SERVICE REQUIREMENTS FOR PIPING COMPONENTS

K305 PIPE

Pipe includes components designated as "tube" or "tubing" in the material specification, when intended for pressure service.

TABLE K305.1.2
REQUIRED ULTRASONIC OR EDDY CURRENT EXAMINATION OF PIPE AND TUBING FOR LONGITUDINAL DEFECTS

Diameter, mm (in.)	Examination Required	Paragraph Reference
$d < 3.2$ ($\frac{1}{8}$) or $D < 6.4$ ($\frac{1}{4}$)	None	...
$3.2 \le d \le 17.5$ ($\frac{11}{16}$) and $6.4 \le D \le 25.4$ (1)	Eddy Current (ET) (1) or Ultrasonic (UT)	K344.8 K344.6
$d > 17.5$ or $D > 25.4$	Ultrasonic (UT)	K344.6

NOTE:
(1) This examination is limited to cold drawn austenitic stainless steel pipe and tubing.

K305.1 Requirements

K305.1.1 General. Pipe and tubing shall be either seamless or longitudinally welded with straight seam and a joint quality factor $E_j = 1.00$, examined in accordance with Note (2) of Table K341.3.2.

K305.1.2 Additional Examination. Pipe and tubing shall have passed a 100% examination for longitudinal defects in accordance with Table K305.1.2. This examination is in addition to acceptance tests required by the material specification.

K305.1.3 Heat Treatment. Heat treatment, if required, shall be in accordance with para. K331.

K305.1.4 Unlisted Pipe and Tubing. Unlisted pipe and tubing may be used only in accordance with para. K302.2.3.

K306 FITTINGS, BENDS, AND BRANCH CONNECTIONS

Pipe and other materials used in fittings, bends, and branch connections shall be suitable for the manufacturing or fabrication process and otherwise suitable for the service.

K306.1 Pipe Fittings

K306.1.1 General. All castings shall have a casting

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:14 2005

A00 **K323.2.2 Lower Temperature Limits, Listed Materials**

(a) The lowest permitted service temperature for a component or weld shall be the impact test temperature determined in accordance with para. K323.3.4(a), except as provided in (b) or (c) below.

(b) For a component or weld subjected to a longitudinal or circumferential stress ≤ 41 MPa (6 ksi), the lowest service temperature shall be the lower of −46°C (−50°F) or the impact test temperature determined in para. K323.3.4(a).

(c) For materials exempted from Charpy testing by Note (6) of Table K323.3.1, the service temperature shall not be lower than −46°C (−50°F).

A00 **K323.2.3 Temperature Limits, Unlisted Materials.** An unlisted material acceptable under para. K323.1.2 shall be qualified for service at all temperatures within a stated range from design minimum temperature to design (maximum) temperature, in accordance with para. K323.2.4. The requirements of para. K323.2.1(c) also apply.

K323.2.4 Verification of Serviceability

A01 *(a)* When an unlisted material is used, or when a listed material is to be used above the highest temperature for which stress values appear in Appendix K, the designer is responsible for demonstrating the validity of the allowable stresses and other design limits, and of the approach taken in using the material, including the derivation of stress data and the establishment of temperature limits.

(b) Paragraph 323.2.4(b) applies except that allowable stress values shall be determined in accordance with para. K302.3.

K323.3 Impact Testing Methods and Acceptance Criteria

K323.3.1 General. Impact testing shall be performed in accordance with Table K323.3.1 on representative samples using the testing methods described in paras. K323.3.2, K323.3.3, and K323.3.4. Acceptance criteria are described in para. K323.3.5.

K323.3.2 Procedure. Paragraph 323.3.2 applies.

K323.3.3 Test Specimens

(a) Each set of impact test specimens shall consist of three specimen bars. Impact tests shall be made using standard 10 mm (0.394 in.) square cross section Charpy V-notch specimen bars oriented in the transverse direction.

(b) Where component size and/or shape does not permit specimens as specified in (a) above, standard 10 mm square cross-section longitudinal Charpy specimens may be prepared.

(c) Where component size and/or shape does not permit specimens as specified in (a) or (b) above, subsize longitudinal Charpy specimens may be prepared. Test temperature shall be reduced in accordance with Table 323.3.4. See also Table K323.3.1, Note (6).

(d) If necessary in (a), (b), or (c) above, corners of specimens parallel to and on the side opposite the notch may be as shown in Fig. K323.3.3.

K323.3.4 Test Temperatures. For all Charpy impact tests, the test temperature criteria in (a) or (b) below shall be observed.

(a) Charpy impact tests shall be conducted at a temperature no higher than the lowest metal temperature at which a piping component or weld will be subjected to a stress greater than 41 MPa (6 ksi). In specifying the required test temperature, the following shall be considered:

(1) range of operating conditions;

(2) upset conditions;

(3) ambient temperature extremes; and

(4) required leak test temperature.

(b) Where the largest possible test specimen has a width along the notch less than the lesser of 80% of the material thickness or 8 mm (0.315 in.), the test shall be conducted at a reduced temperature in accordance with Table 323.3.4, considering the temperature as reduced below the test temperature required by (a) above.

K323.3.5 Acceptance Criteria

(a) Minimum Energy Requirements for Materials Other Than Bolting. The applicable minimum impact energy requirements for materials shall be those shown in Table K323.3.5. Lateral expansion shall be measured in accordance with ASTM A 370 (for title see para. 323.3.2). The results shall be included in the impact test report.

(b) Minimum Energy Requirements for Bolting Materials. The applicable minimum energy requirements shall be those shown in Table K323.3.5 except as provided in Table K323.3.1.

(c) Weld Impact Test Requirements. Where two base metals having different required impact energy values are joined by welding, the impact test energy requirements shall equal or exceed the requirements of the base material having the lower required impact energy.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:15 2005

(d) Retests

(1) Retest for Absorbed Energy Criteria. When the average value of the three specimens equals or exceeds the minimum value permitted for a single specimen, and the value for more than one specimen is below the required average value, or when the value for one specimen is below the minimum value permitted for a single specimen, a retest of three additional specimens shall be made. The value for each of these retest specimens shall equal or exceed the required average value.

(2) Retest for Erratic Test Results. When an erratic result is caused by a defective specimen or uncertainty in the test, a retest will be allowed. The report giving

A01

TABLE K323.3.1
IMPACT TESTING REQUIREMENTS

	Test Characteristics	Column A Pipe, Tubes, and Components Made From Pipe or Tubes	Column B Other Components, Fittings, Etc.	Column C Bolts
Tests on Materials	Number of tests	As required by the material specification, or one test set per lot [see Note (1)], whichever is greater, except as permitted by Note (6).		
	Location and orientation of specimens [see Note (2)]	(a) Transverse to the longitudinal axis, with notch parallel to axis. [See Note (3).] (b) Where component size and/or shape does not permit specimens as specified in (a) above, paras. K323.3.3(b), (c), and (d) apply as needed.	(a) Transverse to the direction of maximum elongation during rolling or to direction of major working during forging. Notch shall be oriented parallel to direction of maximum elongation or major working. (b) If there is no single identifiable axis, e.g., for castings or triaxial forgings, specimens shall either meet the longitudinal values of Table K323.3.5, or three sets of orthogonal specimens shall be prepared, and the lowest impact values obtained from any set shall meet the transverse values of Table K323.3.5. (c) Where component size and/or shape does not permit specimens as specified in (a) or (b) above, paras. K323.3.3(c) and (d) apply as needed.	(a) Bolts ≤ 52 mm (2 in.) nominal size made in accordance with ASTM A 320 shall meet the impact requirements of that specification. (b) For all other bolts, longitudinal specimens shall be taken. The impact values obtained shall meet the transverse values of Table K323.3.5.
Tests on Welds in Fabrication or Assembly	Test pieces [see Note (5)]	Test pieces for preparation of impact specimens shall be made for each welding procedure, type of electrode, or filler metal (i.e., AWS E-XXXX classification) and each flux to be used. All test pieces shall be subject to heat treatment, including cooling rates and aggregate time at temperature or temperatures, essentially the same as the heat treatment which the finished component will have received.		
	Number of test pieces [see Note (4)]	(1) One test piece with a thickness T for each range of material thicknesses which can vary from $\frac{1}{2}T$ to $T + 6$ mm ($\frac{1}{4}$ in.). (2) Unless otherwise specified in this Chapter [see Note (3)] or the engineering design, test pieces need not be made from individual material lots, or from material for each job, provided welds in other certified material of the same thickness ranges and to the same specification (type and grade, not heat or lot) have been tested as required and the records of those tests are made available.		
	Location and orientation of specimens	(1) Weld metal impact specimens shall be taken across the weld with the notch in the weld metal. Each specimen shall be oriented so that the notch axis is normal to the surface of the material and one face of the specimen shall be within 1.5 mm ($\frac{1}{16}$ in.) of the surface of the material. (2) Heat affected zone impact specimens shall be taken across the weld and have sufficient length to locate the notch in the heat affected zone, after etching. The notch shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone material as possible in the resulting fracture. (3) The impact values obtained from both the weld metal and heat affected zone specimens shall be compared to the transverse values in Table K323.3.5 for the determination of acceptance criteria.

TABLE K326.1
COMPONENT STANDARDS[1]

Standard or Specification	Designation [Note (3)]
Bolting	
Square and Hex Bolts and Screws, Inch Series; Including Hex Cap Screws and Lag Screws	*ASME B18.2.1
Square and Hex Nuts (Inch Series)	*ASME B18.2.2
Metallic Fittings, Valves, and Flanges	
Pipe Flanges and Flanged Fittings [Note (2)]	*ASME B16.5
Factory Made Wrought Steel Buttwelding Fittings [Note (2)]	*ASME B16.9
Forged Fittings, Socket Welding and Threaded [Note (2)]	*ASME B16.11
Valves—Flanged, Threaded, and Welding End [Note (2)]	*ASME B16.34
Standard Marking System for Valves, Fittings, Flanges, and Unions	MSS SP-25
High Pressure Chemical Industry Flanges and Threaded Stubs for Use with Lens Gaskets	MSS SP-65
Metallic Pipe and Tubes	
Welded and Seamless Wrought Steel Pipe [Note (2)]	*ASME B36.10M
Stainless Steel Pipe [Note (2)]	*ASME B36.19M
Miscellaneous	
Unified Inch Screw Threads (UN and UNR Thread Form)	*ASME B1.1
Specification for Threading, Gaging and Thread Inspection of Casing, Tubing, and Line Pipe Threads	API 5B
Metallic Gaskets for Pipe Flanges	*ASME B16.20
Buttwelding Ends	*ASME B16.25
Surface Texture (Surface Roughness, Waviness, and Lay)	*ASME B46.1

NOTES:
(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.
(2) The use of components made in accordance with these standards is permissible provided they meet all of the requirements of this Chapter.
(3) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.

PART 9
FABRICATION, ASSEMBLY, AND ERECTION

K327 GENERAL

Piping materials and components are prepared for assembly and erection by one or more of the fabrication processes covered in paras. K328, K330, K331, K332, and K333. When any of these processes is used in assembly or erection, requirements are the same as for fabrication.

K328 WELDING

Welding which conforms to the requirements of para. K328 may be used in accordance with para. K311.

K328.1 Welding Responsibility

Each employer is responsible for the welding done by the personnel of his organization and shall conduct the tests required to qualify welding procedures, and to qualify and as necessary requalify welders and welding operators.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:16 2005

K328.2 Welding Qualifications

K328.2.1 Qualification Requirements. Qualification of the welding procedures to be used and of the performance of welders and welding operators shall comply with the requirements of the BPV Code, Section IX, except as modified herein.

A01 *(a)* Impact tests shall be performed for all procedure qualifications in accordance with para. K323.3.

(b) Test weldments shall be made using the same specification and type or grade of base metal(s), and the same specification and classification of filler metal(s) as will be used in production welding.

(c) Test weldments shall be subjected to essentially the same heat treatment, including cooling rate and cumulative time at temperature, as the production welds.

(d) When tensile specimens are required by Section IX, the yield strength shall also be determined, using the method required for the base metal. The yield strength of each test specimen shall be not less than the specified minimum yield strength (SMYS) for the base metals joined. Where two base metals having different SMYS values are joined by welding, the yield strength of each test specimen shall be not less than the lower of the two SMYS values.

(e) Mechanical testing is required for all performance qualification tests.

(f) Qualification on pipe or tubing shall also qualify for plate, but qualification on plate does not qualify for pipe or tubing.

(g) For thickness greater than 51 mm (2 in.), the procedure test coupon shall be at least 75% as thick as the thickest joint to be welded in production.

(h) Paragraph 328.2.1(f) applies.

K328.2.2 Procedure Qualification by Others. Qualification of welding procedures by others is not permitted.

K328.2.3 Performance Qualification by Others. Welding performance qualification by others is not permitted.

K328.2.4 Qualification Records. Paragraph 328.2.4 applies.

K328.2.5 Performance Requalification. Requalification of welders and welding operators is required in accordance with para. K328.2.1 when:

(a) welder or welding operator has not used the specific process for a period of 3 months or more; or

(b) there is specific reason to question the individual's ability to produce welds that meet the requirements of this Chapter.

K328.3 Materials

K328.3.1 Filler Metal. Filler metal shall be specified in the engineering design and shall conform to the requirements of the BPV Code, Section IX. A filler metal not yet incorporated in Section IX may be used with the owner's approval if a procedure qualification test, including an all-weld-metal test, is first successfully made.

K328.3.2 Weld Backing Material. Backing rings shall not be used.

K328.3.3 Consumable Inserts. Paragraph 328.3.3 applies, except that procedures shall be qualified as required by para. K328.2.

K328.4 Preparation for Welding

K328.4.1 Cleaning. Paragraph 328.4.1 applies.

K328.4.2 End Preparation

(a) General

(1) Butt weld end preparation is acceptable only if the surface is machined or ground to bright metal.

(2) Butt welding end preparation contained in ASME B16.25 or any other end preparation which meets the procedure qualification is acceptable. [For convenience, the basic bevel angles taken from B16.25, with some additional J-bevel angles, are shown in Fig. 328.4.2 sketches (a) and (b).]

(b) Circumferential Welds

(1) If components ends are trimmed as shown in Fig. 328.4.2 sketch (a) or (b) to accommodate consumable inserts, or as shown in Fig. K328.4.3 to correct internal misalignment, such trimming shall not result in a finished wall thickness before welding less than the required minimum wall thickness t_m.

(2) It is permissible to size pipe ends of the same nominal size to improve alignment, if wall thickness requirements are maintained.

(3) Where necessary, weld metal may be deposited on the inside or outside of the component to permit alignment or provide for machining to ensure satisfactory seating of inserts.

(4) When a butt weld joins sections of unequal wall thickness and the thicker wall is more than $1\frac{1}{2}$ times the thickness of the other, end preparation and geometry shall be in accordance with acceptable designs for unequal wall thickness in ASME B16.5.

TABLE D300 (CONT'D)

NOTES:

(1) Stress intensification and flexibility factor data in Table D300 are for use in the absence of more directly applicable data (see para. 319.3.6). Their validity has been demonstrated for $D/\overline{T} \leq 100$.

(2) The flexibility factor k in the Table applies to bending in any plane. The flexibility factors k and stress intensification factors i shall not be less than unity; factors for torsion equal unity. Both factors apply over the effective arc length (shown by heavy center lines in the sketches) for curved and miter bends, and to the intersection point for tees.

(3) A single intensification factor equal to $0.9/h^{2/3}$ may be used for both i_i and i_o if desired.

(4) The values of k and i can be read directly from Chart A by entering with the characteristic h computed from the formulas given above. Nomenclature is as follows:

$\overline{T}$ = for elbows and miter bends, the nominal wall thickness of the fitting
= for tees, the nominal wall thickness of the matching pipe
$\overline{T}_c$ = the crotch thickness of tees
$\overline{T}_r$ = pad or saddle thickness
θ = one-half angle between adjacent miter axes
r_2 = mean radius of matching pipe
R_1 = bend radius of welding elbow or pipe bend
r_x = see definition in para. 304.3.4(c)
s = miter spacing at center line
D_b = outside diameter of branch

(5) Where flanges are attached to one or both ends, the values of k and i in the Table shall be corrected by the factors C_1, which can be read directly from Chart B, entering with the computed h.

(6) The designer is cautioned that cast buttwelded fittings may have considerably heavier walls than that of the pipe with which they are used. Large errors may be introduced unless the effect of these greater thicknesses is considered.

(7) In large diameter thin-wall elbows and bends, pressure can significantly affect the magnitudes of k and i. To correct values from the Table, divide k by

$$\left[1 + 6\left(\frac{P}{E}\right)\left(\frac{r_2}{\overline{T}}\right)^{7/3}\left(\frac{R_1}{r_2}\right)^{1/3}\right]$$

divide i by

$$\left[1 + 3.25\left(\frac{P}{E}\right)\left(\frac{r_2}{\overline{T}}\right)^{5/2}\left(\frac{R_1}{r_2}\right)^{2/3}\right]$$

For consistency, use kPa and mm for SI metric, and psi and in. for US customary notation.

(8) When $\overline{T}_r$ is $> 1\frac{1}{2}\ \overline{T}$, use $h = 4\ \overline{T}/r_2$.

(9) The designer must be satisfied that this fabrication has a pressure rating equivalent to straight pipe.

(10) Factors shown apply to bending. Flexibility factor for torsion equals 0.9.

A01 (11) If $r_x \geq \frac{1}{8}\ D_b$ and $T_c \geq \overline{T}$, a flexibility characteristic of $4.4\ \overline{T}/r_2$ may be used.

(12) The out-of-plane stress intensification factor (SIF) for a reducing branch connection with branch-to-run diameter ratio of $0.5 < d/D < 1.0$ may be nonconservative. A smooth concave weld contour has been shown to reduce the SIF. Selection of the appropriate SIF is the designer's responsibility.

(13) Stress intensification factors for branch connections are based on tests with at least two diameters of straight run pipe on each side of the branch center line. More closely loaded branches may require special consideration.

(14) 2.1 max. or $2.1\ \overline{T}/C_x$, but not less than 1.3. C_x is the fillet weld leg length (see Fig. 328.5.2C. For unequal leg lengths, use the smaller leg for C_x.

APPENDIX E
REFERENCE STANDARDS[1, 2]

(99)
A00
A01

Standards incorporated in this Code by reference, and the names and addresses of the sponsoring organizations are shown in this Appendix. It is not practical to refer to a specific edition of each standard throughout the Code text; instead, the specific edition reference dates are shown here. Subsequent issues and revisions of these referenced standards and any new standards incorporated in the Code by reference in Code Addenda will be listed (after review and acceptance by the Code Committee) in revisions of this Appendix E.

A component ordinarily is not marked to indicate the edition date of the standard to which it is manufactured. It is therefore possible that an item taken from inventory was produced in accordance with a superseded edition, or an edition not yet approved by the Code (because it is of later date than that listed and is in use). If compliance with a specific edition is a requirement of the intended service, it usually will be necessary to state the specific requirement in the purchase specification and to maintain identification of the component until it is put in service.

APPENDIX F
PRECAUTIONARY CONSIDERATIONS

F300 GENERAL

This Appendix provides guidance for the designer in the form of precautionary considerations relating to particular fluid services and piping applications. These are not Code requirements but should be taken into account as applicable in the engineering design. Further information on these subjects can be found in the literature.

A00 A01

F301 DESIGN CONDITIONS

Selection of pressures, temperatures, forces, and other conditions that may apply to the design of piping can be influenced by unusual requirements which should be considered when applicable. These include but are not limited to the following.

F301.4 Ambient Effects

Where fluids can be trapped (e.g., in double seated valves) and subjected to heating and consequent expansion, means of pressure relief should be considered to avoid excessive pressure buildup.

F301.5 Dynamic Effects

geysering: an effect that can occur in piping handling fluids at or near their boiling temperatures under conditions when rapid evolution of vapor within the piping causes rapid expulsion of liquid. In such cases a pressure surge can be generated that may be destructive to the piping. (Geysering usually is associated with vertical pipelines but may occur in inclined lines under certain conditions.)

F301.7 Thermal Expansion and Contraction Effects

bowing during cooldown: an effect that can occur, usually in horizontal piping, on introduction of a fluid at or near its boiling temperature and at a flow rate that allows stratified two-phase flow, causing largecircumferential temperature gradients and possibly unacceptable stresses at anchors, supports, guides, and within pipe walls. (Two-phase flow can also generate excessive pressure oscillations and surges that may damage the piping.)

F301.11 Condensation Effects

A01

Where there is a possibility of condensation occurring inside gaseous fluid piping, means should be considered to provide drainage from low areas to avoid damage from water hammer or corrosion.

F304 PRESSURE DESIGN

F304.7 Pressure Design of Other Metallic Components

F304.7.4 Expansion Joints. The following are specific considerations to be evaluated by the designer when specifying expansion joint requirements, in addition to the guidelines given in EJMA Standards:

(a) susceptibility to stress corrosion cracking of the materials of construction, considering specific alloy content, method of manufacture, and final heat treated condition;

(b) consideration of not only the properties of the flowing medium but also the environment external to the expansion joint and the possibility of condensation or ice formation due to the operation of the bellows at a reduced temperature;

(c) consideration of specifying a minimum bellows or ply thickness. The designer is cautioned that requiring excessive bellows thickness may reduce the fatigue life of the expansion joint and increase end reactions.

(d) accessibility of the expansion joint for maintenance and inspection;

(e) need for leak tightness criteria for mechanical seals on slip type joints;

(f) specification of installation procedures and shipping or preset bars so that the expansion joint will not be extended, compressed, or offset to compensate for improper alignment of piping, other than the intentional offset specified by the piping designer;

(g) need to request data from the expansion joint manufacturer, including:

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:23 2005

(1) effective thrust area;

(2) lateral, axial, and rotational stiffness (spring constant);

(3) calculated design cycle life under specified design conditions;

(4) friction force in hinges, tie rods, etc.;

(5) installed length and weight;

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:23 2005

(6) requirements for additional support or restraint in the piping;

(7) expansion joint elements that are designed to be uninsulated during operation;

(8) certification of pressure containing and/or restraining materials of construction;

(9) maximum test pressure;

(10) design calculations.

F307 VALVES

(a) Extended bonnet valves are recommended where necessary to establish a temperature differential between the valve stem packing and the fluid in the piping, to avoid packing leakage and external icing or other heat flux problems. The valve should be positioned to provide this temperature differential. Consideration should be given to possible packing shrinkage in low temperature fluid service.

(b) The effect of external loads on valve operability and leak tightness should be considered.

F308 FLANGES AND GASKETS

F308.2 Specific Flanges

Slip-On Flanges. The need for venting the space between the welds in double-welded slip-on flanges should be considered for fluid services (including vacuum) that require leak testing of the inner fillet weld, or when fluid handled can diffuse into the enclosed space, resulting in possible failure.

F308.4 Gaskets

(a) Gasket materials not subject to cold flow should be considered for use with raised face flanges for fluid services at elevated pressures with temperatures significantly above or below ambient.

(b) Use of full face gaskets with flat faced flanges should be considered when using gasket materials subject to cold flow for low pressure and vacuum services at moderate temperatures. When such gasket materials are used in other fluid services, the use of tongue-and-groove or other gasket-confining flange facings should be considered.

(c) The effect of flange facing finish should be considered in gasket material selection.

F309 BOLTING

F309.1 General

The use of controlled bolting procedures should be considered in high, low, and cycling temperature services, and under conditions involving vibration or fatigue, to reduce:

(a) the potential for joint leakage due to differential thermal expansion;

(b) the possibility of stress relaxation and loss of bolt tension.

F312 FLANGED JOINTS

F312.1 General

Three distinct elements of a flanged joint must act together to provide a leak-free joint: the flanges, the gasket, and the bolting. Factors that affect performance include:

(a) *Selection and Design*

(1) consideration of service conditions (including external loads, bending moments, and application of thermal insulation);

(2) flange rating, type, material, facing, and facing finish (see para. F308.2);

(3) gasket type, material, thickness, and design (see para. F308.4);

(4) bolt material, strength (cold and at temperature), and specifications for tightening of bolts (see para. F309.1); and

(5) design for access to the joint.

(b) *Installation*

(1) condition of flange mating surfaces;

(2) joint alignment and gasket placement before boltup; and

(3) implementation of specified bolting procedures.

F322 DESIGN CONSIDERATIONS FOR SPECIFIC SYSTEMS

F322.6 Pressure Relief Piping

Stop Valves in Pressure Relief Piping. If stop valves are located in pressure relief piping in accordance with para. 322.6.1(a), and if any of these stop valves are to be closed while the equipment is in operation, an authorized person should be present. The authorized person should remain in attendance at a location where

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:23 2005

the operating pressure can be observed and should have access to means for relieving the system pressure in the event of overpressure. Before leaving the station the authorized person should lock or seal the stop valves in the open position.

F323 MATERIALS

A01 *(a)* Selection of materials to resist deterioration in service is not within the scope of this Code. However, suitable materials should be specified or selected for use in piping and associated facilities not covered by this Code but which affect the safety of the piping. Consideration should be given to allowances made for temperature and pressure effects of process reactions, for properties of reaction or decomposition products, and for hazards from instability of contained fluids. Consideration should be given to the use of cladding, lining, or other protective materials to reduce the effects of corrosion, erosion, and abrasion.

(b) Information on material performance in corrosive environments can be found in publications, such as "The Corrosion Data Survey" published by the National Association of Corrosion Engineers.

F323.1 General Considerations

Following are some general considerations which should be evaluated when selecting and applying materials in piping (see also para. FA323.4):

(a) the possibility of exposure of the piping to fire and the melting point, degradation temperature, loss of strength at elevated temperature, and combustibility of the piping material under such exposure;

(b) the susceptibility to brittle failure or failure from thermal shock of the piping material when exposed to fire or to fire-fighting measures, and possible hazards from fragmentation of the material in the event of failure;

(c) the ability of thermal insulation to protect piping against failure under fire exposure (e.g., its stability, fire resistance, and ability to remain in place during a fire);

(d) the susceptibility of the piping material to crevice corrosion under backing rings, in threaded joints, in socket welded joints, and in other stagnant, confined areas;

(e) the possibility of adverse electrolytic effects if the metal is subject to contact with a dissimilar metal;

(f) the compatibility of lubricants or sealants used on threads with the fluid service;

(g) the compatibility of packing, seals, and O-rings with the fluid service;

(h) the compatibility of materials, such as cements, solvents, solders, and brazing materials, with the fluid service;

(i) the chilling effect of sudden loss of pressure on highly volatile fluids as a factor in determining the lowest expected service temperature;

(j) the possibility of pipe support failure resulting from exposure to low temperatures (which may embrittle the supports) or high temperatures (which may weaken them);

(k) the compatibility of materials, including sealants, gaskets, lubricants, and insulation, used in strong oxidizer fluid service (e.g., oxygen or fluorine).

F323.4 Specific Material Considerations — Metals

Following are some specific considerations which should be evaluated when applying certain metals in piping.

(a) Irons — Cast, Malleable, and High Silicon (14.5%). Their lack of ductility and their sensitivity to thermal and mechanical shock.

(b) Carbon Steel, and Low and Intermediate Alloy Steels

(1) the possibility of embrittlement when handling alkaline or strong caustic fluids;

(2) the possible conversion of carbides to graphite during long time exposure to temperatures above 427°C (800°F) of carbon steels, plain nickel steel, carbon-manganese steel, manganese-vanadium steel, and carbon-silicon steel;

(3) the possible conversion of carbides to graphite during long time exposure to temperatures above 468°C (875°F) of carbon-molybdenum steel, manganese-molybdenum-vanadium steel, and chromium-vanadium steel;

(4) the advantages of silicon-killed carbon steel (0.1% silicon minimum) for temperatures above 482°C (900°F);

(5) the possibility of damage due to hydrogen exposure at elevated temperature (see API RP 941); hydrogen damage (blistering) may occur at lower temperatures under exposure to aqueous acid solutions;[1]

[1] Titles of referenced documents are:
API RP 941, Steels for Hydrogen Service at Elevated Temperatures and Pressures in Petroleum Refineries and Petrochemical Plants
NACE MR 0175, Sulfide Stress-Cracking Resistant Metallic Materials for Oil Field Equipment
NACE RP 0472, Methods and Controls to Prevent In-Service Cracking of Carbon Steel (P-1) Welds in Corrosive Petroleum Refining Environments
NACE RP 0170, Protection of Austenitic Stainless Steel in Refineries Against Stress Corrosion Cracking by Use of Neutralizing Solutions During Shutdown

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:24 2005

(6) the possibility of stress corrosion cracking when exposed to cyanides, acids, acid salts, or wet hydrogen sulfide; a maximum hardness limit is usually specified (see NACE MR 0175 and RP 0472);[1]

(7) the possibility of sulfidation in the presence of hydrogen sulfide at elevated temperatures.

(c) High Alloy (Stainless) Steels

(99) (1) the possibility of stress corrosion cracking of austenitic stainless steels exposed to media such as chlorides and other halides either internally or externally; the latter can result from improper selection or application of thermal insulation, or from use of marking inks, paints, labels, tapes, adhesives, and other accessory materials containing chlorides or other halides;

(2) the susceptibility to intergranular corrosion of austenitic stainless steels sensitized by exposure to temperatures between 427°C and 871°C (800°F and 1600°F); as an example, stress corrosion cracking of sensitized metal at room temperature by polythionic acid (reaction of oxidizable sulfur compound, water, and air); stabilized or low carbon grades may provide improved resistance (see NACE RP 0170);[1]

(3) the susceptibility to intercrystalline attack of austenitic stainless steels on contact with liquid metals (including aluminum, antimony, bismuth, cadmium, gallium, lead, magnesium, tin, and zinc) or their compounds;

(4) the brittleness of ferritic stainless steels at room temperature after service at temperature above 371°C (700°F).

(d) Nickel and Nickel Base Alloys

(1) the susceptibility to grain boundary attack of nickel and nickel base alloys not containing chromium when exposed to small quantities of sulfur at temperatures above 316°C (600°F);

(2) the susceptibility to grain boundary attack of nickel base alloys containing chromium at temperatures above 593°C (1100°F) under reducing conditions and above 760°C (1400°F) under oxidizing conditions;

(3) the possibility of stress corrosion cracking of nickel-copper Alloy 400 in hydrofluoric acid vapor in the presence of air, if the alloy is highly stressed (including residual stresses from forming or welding).

(e) Aluminum and Aluminum Alloys

(1) the compatibility with aluminum of thread compounds used in aluminum threaded joints to prevent seizing and galling;

(2) the possibility of corrosion from concrete, mortar, lime, plaster, or other alkaline materials used in buildings or structures;

(3) the susceptibility of Alloy Nos. 5083, 5086, 5154, and 5456 to exfoliation or intergranular attack; and the upper temperature limit of 66°C (150°F) shown in Appendix A to avoid such deterioration.

(f) Copper and Copper Alloys

(1) the possibility of dezincification of brass alloys;

(2) the susceptibility to stress-corrosion cracking of copper-based alloys exposed to fluids such as ammonia or ammonium compounds;

(3) the possibility of unstable acetylide formation when exposed to acetylene.

(g) Titanium and Titanium Alloys. The possibility of deterioration of titanium and its alloys above 316°C (600°F);

(h) Zirconium and Zirconium Alloys. The possibility of deterioration of zirconium and zirconium alloys above 316°C (600°F);

(i) Tantalum. Above 299°C (570°F), the possibility of reactivity of tantalum with all gases except the inert gases. Below 299°C, the possibility of embrittlement of tantalum by nascent (monatomic) hydrogen (but not molecular hydrogen). Nascent hydrogen is produced by galvanic action, or as a product of corrosion by certain chemicals.

(j) Metals With Enhanced Properties. The possible loss of strength, in a material whose properties have been enhanced by heat treatment, during long-continued exposure to temperatures above its tempering temperature.

(k) The desirability of specifying some degree of production impact testing, in addition to the weld procedure qualification tests, when using materials with limited low temperature service experience below the minimum temperature stated in Table A-1.

F331 HEAT TREATMENT

F331.1 Heat Treatment Considerations

Heat treatment temperatures listed in Table 331.1.1 for some P-No. 4 and P-No. 5 materials may be higher than the minimum tempering temperatures specified in the ASTM specifications for the base material. For higher-strength normalized and tempered materials, there is consequently a possibility of reducing tensile properties of the base material, particularly if long holding times at the higher temperatures are used.

APPENDIX Q
QUALITY SYSTEM PROGRAM

A01

[This Appendix is a Code requirement only when specified by the owner in accordance with para. 300(b)(1).]

Design, construction, inspection, examination, testing, manufacture, fabrication, and erection of piping in accordance with this Code shall be performed under a Quality System Program following the principles of an appropriate standard such as the ISO 9000 series.[1] The details describing the quality system shall be documented and shall be available upon request. A determination of the need for registration and/or certification of the quality system program shall be the responsibility of the owner.

---

[1] The series is also available from the American National Standards Institute (ANSI) and the American Society for Quality (ASQ) as American National Standards that are identified by a prefix "Q" replacing the prefix "ISO." Each standard of the series is listed uner Appendix E.

ASME CODE FOR PRESSURE PIPING, B31
AN AMERICAN NATIONAL STANDARD

ASME B31.3a-2000

ADDENDA

to

ASME B31.3-1999 EDITION
PROCESS PIPING

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
Three Park Avenue • New York, NY 10016

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:26 2005

Date of Issuance: July 14, 2000
Mandatory Date: January 14, 2001

This Addenda was approved by The American National Standards Institute and designated ASME B31.3a-2000 on March 3, 2000.

ASME is the registered trademark of The American Society of Mechanical Engineers.

This code or standard was developed under procedures accredited as meeting the criteria for American National Standards. The Standards Committee that approved the code or standard was balanced to assure that individuals from competent and concerned interests have had an opportunity to participate. The proposed code or standard was made available for public review and comment that provides an opportunity for additional public input from industry, academia, regulatory agencies, and the public-at-large.

ASME does not "approve," "rate," or "endorse" any item, construction, proprietary device, or activity.

ASME does not take any position with respect to the validity of any patent rights asserted in connection with any items mentioned in this document, and does not undertake to insure anyone utilizing a standard against liability for infringement of any applicable letters patent, nor assume any such liability. Users of a code or standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, is entirely their own responsibility.

Participation by federal agency representative(s) or person(s) affiliated with industry is not to be interpreted as government or industry endorsement of this code or standard.

ASME accepts responsibility for only those interpretations of this document issued in accordance with the established ASME procedures and policies, which precludes the issuance of interpretations by individuals.

No part of this document may be reproduced in any form,
in an electronic retrieval system or otherwise,
without the prior written permission of the publisher.

SUMMARY OF CHANGES

Addenda to the 1999 Edition of the Code are issued in the form of replacement pages. Revisions, additions, or deletions are incorporated directly into the affected pages. It is advisable, however, that all replaced pages be retained for reference.

Replace or insert the pages listed. Changes given below are identified on the pages by a margin note, **A00**, placed next to the affected area. Revisions to the 1999 Edition are indicated by **99**. For the listing below, the *Page* references the affected area. A margin note, **A00**, placed next to the heading indicates *Location*. Revisions are listed under *Change*.

Page	*Location*	*Change*
iii, v, vi, vii, ix, xii	Contents	Updated to reflect Addenda changes
1, 1.1	300(c)(3)	Revised
8	300.2	Definition of *stress ratio* added
11, 11.1	301	Revised
	301.1	Revised
	301.2.1(d)	Added
	301.2.2(b)	Revised
15	302.3.2	(1) Subparagraphs (a)(1), (a)(2), (a)(3), (d)(1), (d)(2), (d)(3), and (f) revised (2) Subparagraph (d)(8) added

ASME B31.3-1999 Edition Summary of Changes xxvii

Chapter I **Scope and Definitions**
300 General Statements 1
300.1 Scope 2
300.2 Definitions 2
300.3 Nomenclature 9
300.4 Status of Appendices 9

Figure
300.1.1 Diagram Illustrating Application of B31.3 Piping at Equipment 3

Table
300.4 Status of Appendices in B31.3 10

Chapter II **Design**
Part 1 **Conditions and Criteria** 11
301 Design Conditions 11
301.1 Qualifications of the Designer 11
301.2 Design Pressure 11
301.3 Design Temperature 11
301.4 Ambient Effects 12
301.5 Dynamic Effects 12
301.6 Weight Effects 12
301.7 Thermal Expansion and Contraction Effects 12
301.8 Effects of Support, Anchor, and Terminal Movements 13
301.9 Reduced Ductility Effects 13
301.10 Cyclic Effects 13
301.11 Air Condensation Effects 13
302 Design Criteria 13
302.1 General 13
302.2 Pressure-Temperature Design Criteria 13
302.3 Allowable Stresses and Other Stress Limits 14
302.4 Allowances 19
Part 2 **Pressure Design of Piping Components** 19
303 General 19
304 Pressure Design of Components 19
304.1 Straight Pipe 19
304.2 Curved and Mitered Segments of Pipe 20
304.3 Branch Connections 21
304.4 Closures 27

Chapter II	**Design (Cont'd)**	
304.5	Pressure Design of Flanges and Blanks	28
304.6	Reducers	28
304.7	Pressure Design of Other Components	28
Part 3	**Fluid Service Requirements for Piping Components**	29
305	Pipe	29
305.1	General	30
305.2	Specific Requirements	30
306	Fittings, Bends, Miters, Laps, and Branch Connections	30
306.1	Pipe Fittings	30
306.2	Pipe Bends	31
306.3	Miter Bends	31
306.4	Fabricated or Flared Laps	31
306.5	Fabricated Branch Connections	31
307	Valves and Specialty Components	31
307.1	General	32
307.2	Specific Requirements	32
308	Flanges, Blanks, Flange Facings, and Gaskets	32
308.1	General	32
308.2	Specific Requirements for Flanges	32
308.3	Flange Facings	33
308.4	Gaskets	33
309	Bolting	33
309.1	General	33
309.2	Specific Bolting	33
309.3	Tapped Holes	33
Part 4	**Fluid Service Requirements for Piping Joints**	33
310	General	33
311	Welded Joints	33
311.1	General	33
311.2	Specific Requirements	34
312	Flanged Joints	34
312.1	Joints Using Flanges of Different Ratings	34
312.2	Metal to Nonmetal Flanged Joints	34
313	Expanded Joints	34
314	Threaded Joints	34
314.1	General	34
314.2	Specific Requirements	35
315	Tubing Joints	35
315.1	General	35
315.2	Joints Conforming to Listed Standards	35
315.3	Joints Not Conforming to Listed Standards	35
316	Caulked Joints	35
317	Soldered and Brazed Joints	36
317.1	Soldered Joints	36
317.2	Brazed and Braze Welded Joints	36
318	Special Joints	36
318.1	General	36
318.2	Specific Requirements	36
Part 5	**Flexibility and Support**	36
319	Piping Flexibility	36

Wed Feb 02 00:57:28 2005

Chapter II	**Design (Cont'd)**	
319.1	Requirements	36
319.2	Concepts	36
319.3	Properties for Flexibility Analysis	38
319.4	Flexibility Analysis	38
319.5	Reactions	40
319.6	Calculation of Movements	41
319.7	Means of Increasing Flexibility	41
321	Piping Support	42
321.1	General	42
321.2	Fixtures	43
321.3	Structural Attachments	43
321.4	Structural Connections	44
Part 6	**Systems**	44
322	Specific Piping Systems	44
322.3	Instrument Piping	44
322.6	Pressure Relieving Systems	44
Figures		
304.2.1	Nomenclature for Pipe Bends	20.1
304.2.3	Nomenclature for Miter Bends	20.1
304.3.3	Branch Connection Nomenclature	23
304.3.4	Extruded Outlet Header Nomenclature	25
304.5.3	Blanks	29
319.4.4A	Moments in Bends	40
319.4.4B	Moments in Branch Connections	41
Tables		
302.3.3C	Increased Casting Quality Factors, E_c	16
302.3.3D	Acceptance Levels for Castings	16
302.3.4	Longitudinal Weld Joint Quality Factor, E_j	17
302.3.5	Stress-Range Reduction Factors, f	18
304.1.1	Values of Coefficient Y for $t < D/6$	20
304.4.1	BPV Code References for Closures	27
308.2.1	Permissible Sizes/Rating Classes for Slip-On Flanges Used as Lapped Flanges	32
314.2.1	Minimum Thickness of Male Threaded Components	35
Chapter III	**Materials**	
323	General Requirements	47
323.1	Materials and Specifications	47
323.2	Temperature Limitations	47
323.3	Impact Testing Methods and Acceptance Criteria	49
323.4	Fluid Service Requirements for Materials	53
323.5	Deterioration of Materials in Service	54
325	Materials — Miscellaneous	54
325.1	Joining and Auxiliary Materials	54
Figure		
323.2.2A	Minimum Temperatures Without Impact Testing for Carbon Steel Materials	50
323.2.2B	Reduction in Minimum Design Metal Temperature Without Impact Testing	50.1
Tables		
323.2.2	Requirements for Low Temperature Toughness Tests for Metals	48

Copyright by the American Society Of Mechanical Engineers

Chapter III	**Materials (Cont'd)**	
323.3.1	Impact Testing Requirements for Metals	51
323.3.4	Charpy Impact Test Temperature Reduction	52
323.3.5	Minimum Required Charpy V-Notch Impact Values	53
Chapter IV	**Standards for Piping Components**	
326	Dimensions and Ratings of Components	55
326.1	Dimensional Requirements	55
326.2	Ratings of Components	55
326.3	Reference Documents	55
Table		
326.1	Component Standards	56
Chapter V	**Fabrication, Assembly, and Erection**	
327	General	59
328	Welding	59
328.1	Welding Responsibility	59
328.2	Welding Qualifications	59
328.3	Welding Materials	60
328.4	Preparation for Welding	60
328.5	Welding Requirements	62
328.6	Weld Repair	66
330	Preheating	66
330.1	General	66
330.2	Specific Requirements	66
331	Heat Treatment	67
331.1	General	67
331.2	Specific Requirements	68
332	Bending and Forming	71
332.1	General	71
332.2	Bending	71
332.3	Forming	71
332.4	Required Heat Treatment	72
333	Brazing and Soldering	72
333.1	Qualification	72
333.2	Brazing and Soldering Materials	72
333.3	Preparation	72
333.4	Requirements	72
335	Assembly and Erection	72
335.1	General	72
335.2	Flanged Joints	72
335.3	Threaded Joints	73
335.4	Tubing Joints	73
335.5	Caulked Joints	73
335.6	Expanded Joints and Special Joints	73
335.9	Cleaning of Piping	73
Figures		
328.3.2	Typical Backing Rings and Consumable Inserts	61
328.4.2	Typical Butt Weld End Preparation	62
328.4.3	Trimming and Permitted Misalignment	62
328.4.4	Preparation for Branch Connections	63
328.5.2A	Fillet Weld Size	63

Chapter V	**Fabrication, Assembly, and Erection (Cont'd)**	
328.5.2B	Typical Details for Double-Welded Slip-On and Socket Welding Flange Attachment Welds	63
328.5.2C	Minimum Welding Dimensions for Socket Welding Components Other Than Flanges	64
328.5.4A, B, C	Typical Welded Branch Connections	64
328.5.4D	Acceptable Details for Branch Attachment Welds	65
328.5.4E	Acceptable Details for Branch Attachment Suitable for 100% Radiography	65
328.5.5	Typical Fabricated Laps	66
335.3.3	Typical Threaded Joints Using Straight Threads	73
Tables		
330.1.1	Preheat Temperatures	67
331.1.1	Requirements for Heat Treatment	69
Chapter VI	**Inspection, Examination, and Testing**	
340	Inspection	75
340.1	General	75
340.2	Responsibility for Inspection	75
340.3	Rights of the Owner's Inspector	75
340.4	Qualifications of the Owner's Inspector	75
341	Examination	75
341.1	General	75
341.2	Responsibility for Examination	75
341.3	Examination Requirements	75
341.4	Extent of Required Examination	76
341.5	Supplementary Examination	81
342	Examination Personnel	82
342.1	Personnel Qualification and Certification	82
342.2	Specific Requirement	82
343	Examination Procedures	82
344	Types of Examination	82
344.1	General	82
344.2	Visual Examination	82
344.3	Magnetic Particle Examination	82
344.4	Liquid Penetrant Examination	83
344.5	Radiographic Examination	83
344.6	Ultrasonic Examination	83
344.7	In-Process Examination	83
345	Testing	84
345.1	Required Leak Test	84
345.2	General Requirements for Leak Tests	84
345.3	Preparation for Leak Test	85
345.4	Hydrostatic Leak Test	85
345.5	Pneumatic Leak Test	85.1
345.6	Hydrostatic-Pneumatic Leak Test	86
345.7	Initial Service Leak Test	86
345.8	Sensitive Leak Test	86
345.9	Alternative Leak Test	86
346	Records	86
346.2	Responsibility	86

341.3.2	Typical Weld Imperfections	80
Table		
341.3.2	Acceptance Criteria for Welds	77
Chapter VII	**Nonmetallic Piping and Piping Lined With Nonmetals**	
A300	General Statements	89
Part 1	**Conditions and Criteria**	89
A301	Design Conditions	89
A301.2	Design Pressure	89
A301.3	Design Temperature	89
A302	Design Criteria	89
A302.1	General	89
A302.2	Pressure-Temperature Design Criteria	89
A302.3	Allowable Stresses and Other Design Limits for Nonmetals	90
A302.4	Allowances	91
Part 2	**Pressure Design of Nonmetallic Piping Components**	91
A303	General	91
A304	Pressure Design of Nonmetallic Components	91
A304.1	Straight Pipe	91
A304.2	Curved and Mitered Segments of Pipe	92
A304.3	Branch Connections	92
A304.4	Closures	92
A304.5	Pressure Design of Flanges	92
A304.6	Reducers	93
A304.7	Pressure Design of Other Components	93
Part 3	**Fluid Service Requirements for Nonmetallic Piping Components**	93
A305	Pipe	93
A306	Nonmetallic Fittings, Bends, Miters, Laps, and Branch Connections	93
A306.1	Pipe Fittings	93
A306.2	Pipe Bends	93
A306.3	Miter Bends	93
A306.4	Fabricated or Flared Laps	93
A306.5	Fabricated Branch Connections	93
A307	Nonmetallic Valves and Specialty Components	94
A308	Flanges, Blanks, Flange Facings, and Gaskets	94
A308.1	General	94
A308.2	Nonmetallic Flanges	94
A308.3	Flange Facings	94
A308.4	Limitations on Gaskets	94
A309	Bolting	94
A309.1	General	94
A309.2	Specific Bolting	94
A309.3	Tapped Holes in Nonmetallic Components	94
Part 4	**Fluid Service Requirements for Nonmetallic Piping Joints**	94
A310	General	94
A311	Bonded Joints in Plastics	94
A311.1	General	94

Chapter VII	**Nonmetallic Piping and Piping Lined With Nonmetals (Cont'd)**	
A311.2	Specific Requirements	94
A312	Flanged Joints	95
A313	Expanded Joints	95
A314	Threaded Joints	95
A314.1	General	95
A314.2	Specific Requirements	95
A315	Tubing Joints	95
A316	Caulked Joints	95
A318	Special Joints	95
A318.1	General	95
A318.2	Specific Requirements	95
A318.3	Piping Lined With Nonmetals	95
A318.4	Flexible Elastomeric Sealed Joints	96
Part 5	**Flexibility and Support**	96
A319	Flexibility of Nonmetallic Piping	96
A319.1	Requirements	96
A319.2	Concepts	96
A319.3	Properties for Flexibility Analysis	97
A319.4	Analysis	97
A319.5	Reactions	97
A319.6	Movements	97
A319.7	Means of Increasing Flexibility	97
A321	Piping Support	98
A321.5	Supports for Nonmetallic Piping	98
Part 6	**Systems**	98
A322	Specific Piping Systems	98
A322.3	Instrument Piping	98
A322.6	Pressure Relieving Systems	98
Part 7	**Materials**	98
A323	General Requirements	98
A323.1	Materials and Specifications	98
A323.2	Temperature Limitations, Nonmetals	98
A323.4	Fluid Service Requirements for Nonmetallic Materials	99
A323.5	Deterioration of Materials in Service	100
A325	Materials — Miscellaneous	100
Part 8	**Piping Components, Standards**	101
A326	Dimensions and Ratings of Components	101
A326.1	Requirements	101
A326.4	Abbreviations in Table A326.1 and Appendix B	101
Part 9	**Fabrication, Assembly, and Erection**	101
A327	General	101
A328	Bonding of Plastics	101
A328.1	Bonding Responsibility	101
A328.2	Bonding Qualifications	101
A328.3	Bonding Materials and Equipment	104
A328.4	Preparation for Bonding	105
A328.5	Bonding Requirements	105
A328.6	Bonding Repair	106
A328.7	Seal Bonds	106

CHAPTER I
SCOPE AND DEFINITIONS

300 GENERAL STATEMENTS

(a) Identification. This Process Piping Code is a Section of the American Society of Mechanical Engineers Code for Pressure Piping, ASME B31, an American National Standard. It is published as a separate document for convenience of Code users.

(b) Responsibilities

(1) Owner. The owner of a piping installation shall have overall responsibility for compliance with this Code, and for establishing the requirements for design, construction, examination, inspection, and testing which will govern the entire fluid handling or process installation of which the piping is a part. The owner is also responsible for designating piping in certain fluid services. [See paras. 300(d)(4) and (5) and 300(e).]

(2) Designer. The designer is responsible to the owner for assurance that the engineering design of piping complies with the requirements of this Code and with any additional requirements established by the owner.

(3) Manufacturer, Fabricator, and Erector. The manufacturer, fabricator, and erector of piping are responsible for providing materials, components, and workmanship in compliance with the requirements of this Code and of the engineering design.

(4) Owner's Inspector. The owner's Inspector (see para. 340) is responsible to the owner for ensuring that the requirements of this Code for inspection, examination, and testing are met.

(c) Intent of the Code

(1) It is the intent of this Code to set forth engineering requirements deemed necessary for safe design and construction of piping installations.

(2) This Code is not intended to apply to the operation, examination, inspection, testing, maintenance, or repair of piping that has been placed in service. The provisions of this Code may optionally be applied for those purposes, although other considerations may also be necessary.

A00 *(3)* Engineering requirements of this Code, while considered necessary and adequate for safe design, generally employ a simplified approach to the subject. A designer capable of applying a more rigorous analysis shall have the latitude to do so; however, the approach must be documented in the engineering design and its validity accepted by the owner. The approach used shall provide details of design, construction, examination, inspection, and testing for the design conditions of para. 301, with calculations consistent with the design criteria of this Code.

(4) Piping elements should, insofar as practicable, conform to the specifications and standards listed in this Code. Piping elements neither specifically approved nor specifically prohibited by this Code may be used provided they are qualified for use as set forth in applicable Chapters of this Code.

(5) The engineering design shall specify any unusual requirements for a particular service. Where service requirements necessitate measures beyond those required by this Code, such measures shall be specified by the engineering design. Where so specified, the Code requires that they be accomplished.

(6) Compatibility of materials with the service and hazards from instability of contained fluids are not within the scope of this Code. See para. F323.

(d) Determining Code Requirements

(1) Code requirements for design and construction include fluid service requirements, which affect selection and application of materials, components, and joints. Fluid service requirements include prohibitions, limitations, and conditions, such as temperature limits or a requirement for safeguarding (see para. 300.2 and Appendix G). Code requirements for a piping system are the most restrictive of those which apply to any of its elements.

(2) For metallic piping not in Category M or high pressure fluid service, Code requirements are found in Chapters I through VI (the base Code), and fluid service requirements are found in:

(a) Chapter III for materials;

(b) Chapter II, Part 3, for components;

(c) Chapter II, Part 4, for joints.

(3) For nonmetallic piping and piping lined with nonmetals, all requirements are found in Chapter VII. (Paragraph designations begin with "A.")

Wed Feb 02 00:57:30 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617516 681 ■

(4) For piping in a fluid service designated by the owner as Category M (see para. 300.2 and Appendix M), all requirements are found in Chapter VIII. (Paragraph designations begin with "M.")

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:31 2005

(5) For piping in a fluid service designated by the owner as Category D (see para. 300.2 and Appendix M), piping elements restricted to Category D Fluid Service in Chapters I through VII, as well as elements suitable for other fluid services, may be used.

(6) Metallic piping elements suitable for Normal Fluid Service in Chapters I through VI may also be used under severe cyclic conditions unless a specific requirement for severe cyclic conditions is stated.

(e) High Pressure Piping. Chapter IX provides alternative rules for design and construction of piping designated by the owner as being in High Pressure Fluid Service.

(1) These rules apply only when specified by the owner, and only as a whole, not in part.

(2) Chapter IX rules do not provide for Category M Fluid Service. See para. K300.1.4.

(3) Paragraph designations begin with "K."

(f) Appendices. Appendices of this Code contain Code requirements, supplementary guidance, or other information. See para. 300.4 for a description of the status of each Appendix.

300.1 Scope

Rules for the Process Piping Code Section B31.3[1] have been developed considering piping typically found in petroleum refineries; chemical, pharmaceutical, textile, paper, semiconductor, and cryogenic plants; and related processing plants and terminals.

300.1.1 Content and Coverage

(a) This Code prescribes requirements for materials and components, design, fabrication, assembly, erection, examination, inspection, and testing of piping.

(b) This Code applies to piping for all fluids, including:

(1) raw, intermediate, and finished chemicals;

(2) petroleum products;

(3) gas, steam, air, and water;

(4) fluidized solids;

(5) refrigerants; and

(6) cryogenic fluids.

(99) *(c)* See Fig. 300.1.1 for a diagram illustrating the application of B31.3 piping at equipment. The joint connecting piping to equipment is within the scope of B31.3.

[1] B31 references here and elsewhere in this Code are to the ASME B31 Code for Pressure Piping and its various Sections, which are identified and briefly described in the Introduction.

300.1.2 Packaged Equipment Piping.

Also included within the scope of this Code is piping which interconnects pieces or stages within a packaged equipment assembly.

300.1.3 Exclusions.

This Code excludes the following:

(a) piping systems designed for internal gage pressures at or above zero but less than 105 kPa (15 psi), provided the fluid handled is nonflammable, nontoxic, and not damaging to human tissue as defined in 300.2, and its design temperature is from −29°C (−20°F) through 186°C (366°F);

(b) power boilers in accordance with BPV Code[2] Section I and boiler external piping which is required to conform to B31.1;

(c) tubes, tube headers, crossovers, and manifolds of fired heaters, which are internal to the heater enclosure; and

(d) pressure vessels, heat exchangers, pumps, compressors, and other fluid handling or processing equipment, including internal piping and connections for external piping.

300.2 Definitions

Some of the terms relating to piping are defined below. For welding terms not shown here, definitions in accordance with ANSI/AWS Standard A3.0 apply.

air-hardened steel: a steel that hardens during cooling in air from a temperature above its transformation range

anneal heat treatment: see *heat treatment*

arc cutting: a group of cutting processes wherein the severing or removing of metals is effected by melting with the heat of an arc between an electrode and the base metal. (Includes carbon-arc cutting, metal-arc cutting, gas metal-arc cutting, gas tungsten-arc cutting, plasma-arc cutting, and air carbon-arc cutting.) See also *oxygen-arc cutting.*

arc welding (AW): a group of welding processes which produces coalescence of metals by heating them with an arc or arcs, with or without the application of pressure and with or without the use of filler metal

[2] BPV Code references here and elsewhere in this Code are to the ASME Boiler and Pressure Vessel Code and its various Sections as follows:
Section I, Power Boilers
Section II, Materials, Part D
Section V, Nondestructive Examination
Section VIII, Pressure Vessels, Divisions 1 and 2
Section IX, Welding and Brazing Qualifications

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:31 2005

pipe, according to the method of manufacture, are defined as follows:

(a) electric resistance-welded pipe: pipe produced in individual lengths or in continuous lengths from coiled skelp and subsequently cut into individual lengths, having a longitudinal butt joint wherein coalescence is produced by the heat obtained from resistance of the pipe to the flow of electric current in a circuit of which the pipe is a part, and by the application of pressure

(b) furnace butt welded pipe, continuous welded: pipe produced in continuous lengths from coiled skelp and subsequently cut into individual lengths, having its longitudinal butt joint forge welded by the mechanical pressure developed in passing the hot-formed and edge-heated skelp through a set of round pass welding rolls

(c) electric-fusion welded pipe: pipe having a longitudinal butt joint wherein coalescence is produced in the preformed tube by manual or automatic electric-arc welding. The weld may be single (welded from one side) or double (welded from inside and outside) and may be made with or without the addition of filler metal.

(d) double submerged-arc welded pipe: pipe having a longitudinal butt joint produced by at least two passes, one of which is on the inside of the pipe. Coalescence is produced by heating with an electric arc or arcs between the bare metal electrode or electrodes and the work. The welding is shielded by a blanket of granular fusible material on the work. Pressure is not used and filler metal for the inside and outside welds is obtained from the electrode or electrodes.

(e) seamless pipe: pipe produced by piercing a billet followed by rolling or drawing, or both

(f) spiral welded pipe: pipe having a helical seam with either a butt, lap, or lock-seam joint which is welded using either an electrical resistance, electric fusion or double-submerged arc welding process

pipe-supporting elements: pipe-supporting elements consist of fixtures and structural attachments as follows:

(a) fixtures: fixtures include elements which transfer the load from the pipe or structural attachment to the supporting structure or equipment. They include hanging type fixtures, such as hanger rods, spring hangers, sway braces, counterweights, turnbuckles, struts, chains, guides, and anchors; and bearing type fixtures, such as saddles, bases, rollers, brackets, and sliding supports.

(b) structural attachments: structural attachments include elements which are welded, bolted, or clamped to the pipe, such as clips, lugs, rings, clamps, clevises, straps, and skirts

piping: assemblies of piping components used to convey, distribute, mix, separate, discharge, meter, control, or snub fluid flows. Piping also includes pipe-supporting elements, but does not include support structures, such as building frames, bents, foundations, or any equipment excluded from this Code (see para. 300.1.3).

piping components: mechanical elements suitable for joining or assembly into pressure-tight fluid-containing piping systems. Components include pipe, tubing, fittings, flanges, gaskets, bolting, valves, and devices such as expansion joints, flexible joints, pressure hoses, traps, strainers, in-line portions of instruments, and separators.

piping elements: any material or work required to plan and install a piping system. Elements of piping include design specifications, materials, components, supports, fabrication, examination, inspection, and testing.

piping installation: designed piping systems to which a selected Code Edition and Addenda apply

piping system: interconnected piping subject to the same set or sets of design conditions

plasma arc cutting (PAC): an arc cutting process that uses a constricted arc and removes molten metal with a high velocity jet of ionized gas issuing from the constricting orifice

preheating: the application of heat to the base material immediately before or during a forming, welding, or cutting process. See para. 330.

postweld heat treatment: see *heat treatment*

procedure qualification record (PQR): a document listing all pertinent data, including the essential variables employed and the test results, used in qualifying the procedure specification

process unit: an area whose boundaries are designated by the engineering design within which reactions, separations, and other processes are carried out. Examples of installations which are *not* classified as process units are loading areas or terminals, bulk plants, compounding plants, and tank farms and storage yards.

quench annealing: see *solution heat treatment* under *heat treatment*

quenching: see *heat treatment*

reinforcement: see paras. 304.3 and A304.3. See also *weld reinforcement.*

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:31 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617519 390 ■

root opening: the separation between the members to be joined, at the root of the joint

safeguarding: provision of protective measures of the types outlined in Appendix G, where deemed necessary. See Appendix G for detailed discussion.

seal bond: a bond intended primarily to provide joint tightness against leakage in nonmetallic piping

seal weld: a weld intended primarily to provide joint tightness against leakage in metallic piping

semiautomatic arc welding: arc welding with equipment which controls only the filler metal feed. The advance of the welding is manually controlled.

(99) *severe cyclic conditions:* conditions applying to specific piping components or joints in which S_E computed in accordance with para. 319.4.4 exceeds $0.8S_A$ (as defined in para. 302.3.5), and the equivalent number of cycles (N in para. 302.3.5) exceeds 7000; or other conditions which the designer determines will produce an equivalent effect

shall: a term which indicates that a provision is a Code requirement

shielded metal-arc welding (SMAW): an arc welding process which produces coalescence of metals by heating them with an arc between a covered metal electrode and the work. Shielding is obtained from decomposition of the electrode covering. Pressure is not used and filler metal is obtained from the electrode.

should: a term which indicates that a provision is recommended as good practice but is not a Code requirement

size of weld:

(a) fillet weld: the leg lengths (the leg length for equal-leg welds) of the sides, adjoining the members welded, of the largest triangle that can be inscribed within the weld cross section. For welds between perpendicular members, the definitions in Fig. 328.5.2A apply.

NOTE: When the angle between members exceeds 105 deg, size is of less significance than effective throat (see also *throat of a fillet weld*).

(b) groove weld: the joint penetration (depth of bevel plus the root penetration when specified). The size of a groove weld and its effective throat are the same.

slag inclusion: nonmetallic solid material entrapped in weld metal or between weld metal and base metal

soldering: a metal joining process wherein coalescence is produced by heating to suitable temperatures and by using a nonferrous alloy fusible at temperatures below 427°C (800°F) and having a melting point below that of the base metals being joined. The filler metal is distributed between closely fitted surfaces of the joint by capillary attraction. In general, solders are lead-tin alloys and may contain antimony, bismuth, and other elements.

solution heat treatment: see *heat treatment*

stress ratio: see Fig. 323.2.2B. A00

stress relief: see *heat treatment*

stress terms frequently used:

(a) basic allowable stress: this term, symbol S, represents the stress value for any material determined by the appropriate stress basis in para. 302.3.2

(b) bolt design stress: this term represents the design stress used to determine the required cross-sectional area of bolts in a bolted joint

(c) hydrostatic design basis: selected properties of plastic piping materials to be used in accordance with ASTM D 2837 or D 2992 to determine the HDS [see (d) below] for the material

(d) hydrostatic design stress (HDS): the maximum continuous stress due to internal pressure to be used in the design of plastic piping, determined from the hydrostatic design basis by use of a service (design) factor

submerged arc welding (SAW): an arc welding process which produces coalescence of metals by heating them with an arc or arcs between a bare metal electrode or electrodes and the work. The arc is shielded by a blanket of granular, fusible material on the work. Pressure is not used and filler metal is obtained from the electrode and sometimes from a supplemental source (welding rod, flux, or metal granules).

tack weld: a weld made to hold parts of a weldment in proper alignment until the final welds are made

tempering: see *heat treatment*

thermoplastic: a plastic which is capable of being repeatedly softened by increase of temperature and hardened by decrease of temperature

thermosetting resin: a resin capable of being changed into a substantially infusible or insoluble product when cured at room temperature, or by application of heat, or by chemical means

throat of a fillet weld:

(a) theoretical throat: the perpendicular distance

CHAPTER II
DESIGN

PART 1
CONDITIONS AND CRITERIA

A00 301 DESIGN CONDITIONS

Paragraph 301 states the qualifications of the Designer, defines the temperatures, pressures, and forces applicable to the design of piping, and states the consideration that shall be given to various effects and their consequent loadings. See also Appendix F, para. F301.

A00 301.1 Qualifications of the Designer

The Designer is the person(s) in charge of the engineering design of a piping system and shall be experienced in the use of this Code.

The qualifications and experience required of the Designer will depend on the complexity and criticality of the system and the nature of the individual's experience. The owner's approval is required if the individual does not meet at least one of the following criteria.

(a) Completion of an engineering degree, requiring four or more years of full-time study, plus a minimum of 5 years experience in the design of related pressure piping.

(b) Professional Engineering registration, recognized by the local jurisdiction, and experience in the design of related pressure piping.

(c) Completion of an engineering associates degree, requiring at least 2 years of full-time study, plus a minimum of 10 years experience in the design of related pressure piping.

(d) Fifteen years experience in the design of related pressure piping. Experience in the design of related pressure piping is satisfied by piping design experience that includes design calculations for pressure, sustained and occasional loads, and piping flexibility.

301.2 Design Pressure

301.2.1 General

(a) The design pressure of each component in a piping system shall be not less than the pressure at the most severe condition of coincident internal or external pressure and temperature (minimum or maximum) expected during service, except as provided in para. 302.2.4.

(b) The most severe condition is that which results in the greatest required component thickness and the highest component rating.

(c) When more than one set of pressure-temperature conditions exist for a piping system, the conditions governing the rating of components conforming to listed standards may differ from the conditions governing the rating of components designed in accordance with para. 304.

(d) When a pipe is separated into individualized pressure-containing chambers (including jacketed piping, blanks, etc.), the partition wall shall be designed on the basis of the most severe coincident temperature (minimum or maximum) and differential pressure between the adjoining chambers expected during service, except as provided in para. 302.2.4. A00

301.2.2 Required Pressure Containment or Relief

(a) Provision shall be made to safely contain or relieve (see para. 322.6.3) any pressure to which the piping may be subjected. Piping not protected by a pressure relieving device, or that can be isolated from a pressure relieving device, shall be designed for at least the highest pressure that can be developed.

(b) Sources of pressure to be considered include ambient influences, pressure oscillations and surges, improper operation, decomposition of unstable fluids, static head, and failure of control devices. A00

(c) The allowances of para. 302.2.4(f) are permitted, provided that the other requirements of para. 302.2.4 are also met.

301.3 Design Temperature

The design temperature of each component in a piping system is the temperature at which, under the coincident pressure, the greatest thickness or highest component rating is required in accordance with para. 301.2. (To satisfy the requirements of para. 301.2,

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:32 2005

different components in the same piping system may have different design temperatures.)

In establishing design temperatures, consider at least the fluid temperatures, ambient temperatures, solar radiation, heating or cooling medium temperatures, and the applicable provisions of paras. 301.3.2, 301.3.3, and 301.3.4.

301.3.1 Design Minimum Temperature. The design minimum temperature is the lowest component temperature expected in service. This temperature may establish special design requirements and material qualification requirements. See also paras. 301.4.4 and 323.2.2.

301.3.2 Uninsulated Components

(a) For fluid temperatures below 65°C (150°F), the component temperature shall be taken as the fluid temperature unless solar radiation or other effects result in a higher temperature.

(b) For fluid temperatures 65°C (150°F) and above, unless a lower average wall temperature is determined by test or heat transfer calculation, the temperature for uninsulated components shall be no less than the following values:

(1) valves, pipe, lapped ends, welding fittings, and other components having wall thickness comparable to that of the pipe: 95% of the fluid temperature;

(2) flanges (except lap joint) including those on fittings and valves: 90% of the fluid temperature;

(3) lap joint flanges: 85% of the fluid temperature;

(4) bolting: 80% of the fluid temperature.

301.3.3 Externally Insulated Piping. The component design temperature shall be the fluid temperature unless calculations, tests, or service experience based

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:32 2005

on measurements support the use of another temperature. Where piping is heated or cooled by tracing or jacketing, this effect shall be considered in establishing component design temperatures.

301.3.4 Internally Insulated Piping. The component design temperature shall be based on heat transfer calculations or tests.

301.4 Ambient Effects

See Appendix F, para. F301.4.

301.4.1 Cooling: Effects on Pressure. The cooling of a gas or vapor in a piping system may reduce the pressure sufficiently to create an internal vacuum. In such a case, the piping shall be capable of withstanding the external pressure at the lower temperature, or provision shall be made to break the vacuum.

301.4.2 Fluid Expansion Effects. Provision shall be made in the design either to withstand or to relieve increased pressure caused by the heating of static fluid in a piping component. See also para. 322.6.3(b)(2).

301.4.3 Atmospheric Icing. Where the design minimum temperature of a piping system is below 0°C (32°F), the possibility of moisture condensation and buildup of ice shall be considered and provisions made in the design to avoid resultant malfunctions. This applies to surfaces of moving parts of shutoff valves, control valves, pressure relief devices including discharge piping, and other components.

301.4.4 Low Ambient Temperature. Consideration shall be given to low ambient temperature conditions for displacement stress analysis.

301.5 Dynamic Effects

See Appendix F, para. F301.5.

301.5.1 Impact. Impact forces caused by external or internal conditions (including changes in flow rate, hydraulic shock, liquid or solid slugging, flashing, and geysering) shall be taken into account in the design of piping.

301.5.2 Wind. The effect of wind loading shall be taken into account in the design of exposed piping. The method of analysis may be as described in ASCE 7, Minimum Design Loads for Buildings and Other Structures, or the Uniform Building Code.

301.5.3 Earthquake. Piping shall be designed for earthquake-induced horizontal forces. The method of analysis may be as described in ASCE 7-88 or the Uniform Building Code.

301.5.4 Vibration. Piping shall be designed, arranged, and supported so as to eliminate excessive and harmful effects of vibration which may arise from such sources as impact, pressure pulsation, resonance in compressors, and wind loads.

301.5.5 Discharge Reactions. Piping shall be designed, arranged, and supported so as to withstand reaction forces due to let-down or discharge of fluids.

301.6 Weight Effects

The following weight effects, combined with loads and forces from other causes, shall be taken into account in the design of piping.

301.6.1 Live Loads. These loads include the weight of the medium transported or the medium used for test. Snow and ice loads due to both environmental and operating conditions shall be considered.

301.6.2 Dead Loads. These loads consist of the weight of piping components, insulation, and other superimposed permanent loads supported by the piping.

301.7 Thermal Expansion and Contraction Effects

The following thermal effects, combined with loads and forces from other causes, shall be taken into account in the design of piping. See also Appendix F, para. F301.7.

301.7.1 Thermal Loads Due to Restraints. These loads consist of thrusts and moments which arise when free thermal expansion and contraction of the piping are prevented by restraints or anchors.

301.7.2 Loads Due to Temperature Gradients. These loads arise from stresses in pipe walls resulting from large rapid temperature changes or from unequal temperature distribution as may result from a high heat flux through a comparatively thick pipe or stratified two-phase flow causing bowing of the line.

301.7.3 Loads Due to Differences in Expansion Characteristics. These loads result from differences in thermal expansion where materials with different thermal expansion coefficients are combined, as in bimetallic, lined, jacketed, or metallic–nonmetallic piping.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:32 2005

ature for bolting materials shall not exceed the lowest of the following:

A00 *(1)* except as provided in (3) below, the lower of one-fourth of specified minimum tensile strength at room temperature (S_T) and one-fourth of tensile strength at temperature;

A00 *(2)* except as provided in (3) below, the lower of two-thirds of specified minimum yield strength at room temperature (S_Y) and two-thirds of yield strength at temperature;

A00 *(3)* at temperatures below the creep range, for bolting materials whose strength has been enhanced by heat treatment or strain hardening, the lower of one-fifth of S_T and one-fourth of S_Y (unless these values are lower than corresponding values for annealed material, in which case the annealed values shall be used);

(4) two-thirds of the "yield strength at temperature" [see para. 302.3.2(f)];

(5) 100% of the average stress for a creep rate of 0.01% per 1000 hr;

(6) 67% of the average stress for rupture at the end of 100,000 hr;

(7) 80% of minimum stress for rupture at the end of 100,000 hr.

(b) Cast Iron. Basic allowable stress values at temperature for cast iron shall not exceed the lower of the following:

(1) one-tenth of the specified minimum tensile strength at room temperature;

(2) one-tenth of the tensile strength at temperature [see para. 302.3.2(f)].

(c) Malleable Iron. Basic allowable stress values at temperature for malleable iron shall not exceed the lower of the following:

(1) one-fifth of the specified minimum tensile strength at room temperature;

(2) one-fifth of the tensile strength at temperature [see para. 302.3.2(f)].

(d) Other Materials. Basic allowable stress values at temperature for materials other than bolting materials, cast iron, and malleable iron shall not exceed the lowest of the following:

A00 *(1)* the lower of one-third of S_T and one-third of tensile strength at temperature;

A00 *(2)* except as provided in (3) below, the lower of two-thirds of S_Y and two-thirds of yield strength at temperature;

A00 *(3)* for austenitic stainless steels and nickel alloys having similar stress–strain behavior, the lower of two-thirds of S_Y and 90% of yield strength at temperature [see (e) below];

(4) 100% of the average stress for a creep rate of 0.01% per 1000 hr;

(5) 67% of the average stress for rupture at the end of 100,000 hr;

(6) 80% of the minimum stress for rupture at the end of 100,000 hr;

(7) for structural grade materials, the basic allowable stress shall be 0.92 times the lowest value determined in paras. 302.3.2(d)(1) through (6).

(8) In the application of these criteria, the yield strength at room temperature is considered to be $S_Y R_Y$, and the tensile strength at room temperature is considered to be $1.1 S_T R_T$. A00

(e) Application Limits. Application of stress values determined in accordance with para. 302.3.2(d)(3) is not recommended for flanged joints and other components in which slight deformation can cause leakage or malfunction. [These values are shown in italics or boldface in Table A-1, as explained in Note (4) to Appendix A Tables.] Instead, either 75% of the stress value in Table A-1 or two-thirds of the yield strength at temperature listed in the BPV Code, Section II, Part D, Table Y-1 should be used.

(f) Unlisted Materials. For a material which conforms to para. 323.1.2, the tensile (yield) strength at temperature shall be derived by multiplying the average expected tensile (yield) strength at temperature by the ratio of S_T (S_Y) divided by the average expected tensile (yield) strength at room temperature. A00

302.3.3 Casting Quality Factor E_c

(a) General. The casting quality factors E_c defined herein shall be used for cast components not having pressure-temperature ratings established by standards in Table 326.1.

(b) Basic Quality Factors. Castings of gray and malleable iron, conforming to listed specifications, are assigned a basic casting quality factor E_c of 1.00 (due to their conservative allowable stress basis). For most other metals, static castings which conform to the material specification and have been visually examined as required by MSS SP-55, Quality Standard for Steel Castings for Valves, Flanges and Fittings and Other Piping Components — Visual Method, are assigned a basic casting quality factor E_c of 0.80. Centrifugal castings which meet specification requirements only for chemical analysis, tensile, hydrostatic, and flattening tests, and visual examination are assigned a basic casting quality factor of 0.80. Basic casting quality factors are tabulated for listed specifications in Table A-1A.

(c) Increased Quality Factors. Casting quality factors may be increased when supplementary examinations are performed on each casting. Table 302.3.3C states the increased casting quality factors E_c which may

TABLE 302.3.3C[4]
INCREASED CASTING QUALITY FACTORS, E_C

Supplementary Examination in Accordance With Note(s)	Factor, E_C
(1)	0.85
(2)(a) or (2)(b)	0.85
(3)(a) or (3)(b)	0.95
(1) and (2)(a) or (2)(b)	0.90
(1) and (3)(a) or (3)(b)	1.00
(2)(a) or (2)(b) and (3)(a) or (3)(b)	1.00

NOTES:
(1) Machine all surfaces to a finish of 6.3 μm R_a (250 μin. R_a per ASME B46.1), thus increasing the effectiveness of surface examination.
(2) (a) Examine all surfaces of each casting (magnetic material only) by the magnetic particle method in accordance with ASTM E 709. Judge acceptability in accordance with MSS SP-53, using reference photos in ASTM E 125.
(b) Examine all surfaces of each casting by the liquid penetrant method, in accordance with ASTM E 165. Judge acceptability of flaws and weld repairs in accordance with Table 1 of MSS SP-53, using ASTM E 125 as a reference for surface flaws.
(3) (a) Fully examine each casting ultrasonically in accordance with ASTM E 114, accepting a casting only if there is no evidence of depth of defects in excess of 5% of wall thickness.
(b) Fully radiograph each casting in accordance with ASTM E 142. Judge in accordance with the stated acceptance levels in Table 302.3.3D.
(4) Titles of standards referenced in this Table are as follows:
ASTM
E 114 Practice for Ultrasonic Pulse-Echo Straight-Beam Testing by the Contact Method
E 125 Reference Photographs for Magnetic Particle Indications on Ferrous Castings
E 142 Method for Controlling Quality of Radiographic Testing
E 165 Practice for Liquid Penetrant Inspection Method
E 709 Practice for Magnetic Particle Examination
ASME
B46.1 Surface Texture (Surface Roughness, Waviness and Lay)
MSS
SP-53 Quality Standard for Steel Castings for Valves, Flanges and Fittings and Other Piping Components—Magnetic Particle Examination Method

TABLE 302.3.3D[1]
ACCEPTANCE LEVELS FOR CASTINGS

Material Examined Thickness, T	Applicable Standard	Acceptance Level (or Class)	Acceptable Discontinuities
Steel $T \le 25$ mm (1 in.)	ASTM E 446	1	Types A, B, C
Steel $T > 25$ mm, ≤ 51 mm (2 in.)	ASTM E 446	2	Types A, B, C
Steel $T > 51$ mm, ≤ 114 mm ($4\frac{1}{2}$ in.)	ASTM E 186	2	Categories A, B, C
Steel $T > 114$ mm, ≤ 305 mm (12 in.)	ASTM E 280	2	Categories A, B, C
Aluminum & magnesium	ASTM E 155	...	Shown in reference radiographs
Copper, Ni–Cu	ASTM E 272	2	Codes A, Ba, Bb
Bronze	ASTM E 310	2	Codes A and B

NOTE:
(1) Titles of standards referenced in this Table are as follows:
ASTM
E 155 Reference Radiographs for Inspection of Aluminum and Magnesium Castings
E 186 Reference Radiographs for Heavy-Walled [2 to 4-$\frac{1}{2}$-in. (51 to 114-mm)] Steel Castings
E 272 Reference Radiographs for High-Strength Copper-Base and Nickel-Copper Castings
E 280 Reference Radiographs for Heavy-Walled [4-$\frac{1}{2}$ to 12-in. (114 to 305-mm)] Steel Castings
E 310 Reference Radiographs for Tin Bronze Castings
E 446 Reference Radiographs for Steel Castings Up to 2 in. (51 mm) in Thickness

be used for various combinations of supplementary examination. Table 302.3.3D states the acceptance criteria for the examination methods specified in the Notes to Table 302.3.3C. Quality factors higher than those shown in Table 302.3.3C do not result from combining tests 2a and 2b, or 3a and 3b. In no case shall the quality factor exceed 1.00.

Several of the specifications in Appendix A require machining of all surfaces and/or one or more of these supplementary examinations. In such cases, the appropriate increased quality factor is shown in Table A-1A.

302.3.4 Weld Joint Quality Factor, E_j

(a) Basic Quality Factors. The weld joint quality factors E_j tabulated in Table A-1B are basic factors for straight or spiral longitudinal welded joints for pressure-containing components as shown in Table 302.3.4.

(b) Increased Quality Factors. Table 302.3.4 also indicates higher joint quality factors which may be substituted for those in Table A-1B for certain kinds of welds if additional examination is performed beyond that required by the product specification.

302.3.5 Limits of Calculated Stresses Due to Sustained Loads and Displacement Strains

(a) Internal Pressure Stresses. Stresses due to internal pressure shall be considered safe when the wall

TABLE 302.3.4
LONGITUDINAL WELD JOINT QUALITY FACTOR, E_j

(99)

No.	Type of Joint		Type of Seam	Examination	Factor, E_j
1	Furnace butt weld, continuous weld		Straight	As required by listed specification	0.60 [Note (1)]
2	Electric resistance weld		Straight or spiral	As required by listed specification	0.85 [Note (1)]
3	Electric fusion weld				
	(a) Single butt weld (with or without filler metal)		Straight or spiral	As required by listed specification or this Code	0.80
				Additionally spot radiographed per para. 341.5.1	0.90
				Additionally 100% radiographed per para. 344.5.1 and Table 341.3.2	1.00
	(b) Double butt weld (with or without filler metal)		Straight or spiral [except as provided in 4(a) below]	As required by listed specification or this Code	0.85
				Additionally spot radiographed per para. 341.5.1	0.90
				Additionally 100% radiographed per para. 344.5.1 and Table 341.3.2	1.00
4	Per specific specification				
	(a) API 5L	Submerged arc weld (SAW) Gas metal arc weld (GMAW) Combined GMAW, SAW 	Straight with one or two seams Spiral	As required by specification	0.95

NOTE:
(1) It is not permitted to increase the joint quality factor by additional examination for joint 1 or 2.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:33 2005

thickness of the piping component, including any reinforcement, meets the requirements of para. 304.

(b) External Pressure Stresses. Stresses due to external pressure shall be considered safe when the wall thickness of the piping component, and its means of stiffening, meet the requirements of para. 304.

A00 *(c) Longitudinal Stresses S_L.* The sum of longitudinal stresses in any component in a piping system, due to pressure, weight, and other sustained loadings S_L shall not exceed S_h in (d) below. The thickness of pipe used in calculating S_L shall be the nominal thickness $\overline{T}$ minus mechanical, corrosion, and erosion allowance c, for the location under consideration. The loads due to weight should be based on the nominal thickness of all system components unless otherwise justified in a more rigorous analysis.

(d) Allowable Displacement Stress Range S_A. The computed displacement stress range S_E in a piping system (see para. 319.4.4) shall not exceed the allowable displacement stress range S_A (see paras. 319.2.3 and 319.3.4) calculated by Eq. (1a):

$$S_A = f(1.25S_c + 0.25S_h) \quad (1a)$$

When S_h is greater than S_L, the difference between them may be added to the term $0.25S_h$ in Eq. (1a). In that case, the allowable stress range is calculated by Eq. (1b):

$$S_A = f[1.25(S_c + S_h) - S_L] \quad (1b)$$

In Eqs. (1a) and (1b):

S_c = basic allowable stress[3] at minimum metal temperature expected during the displacement cycle under analysis

S_h = basic allowable stress[3] at maximum metal temperature expected during the displacement cycle under analysis

f = stress range reduction factor,[4] from Table 302.3.5 or calculated by Eq. (1c):[5]

TABLE 302.3.5
STRESS-RANGE REDUCTION FACTORS, f

Cycles, N	Factor, f
7,000 and less	1.0
Over 7,000 to 14,000	0.9
Over 14,000 to 22,000	0.8
Over 22,000 to 45,000	0.7
Over 45,000 to 100,000	0.6
Over 100,000 to 200,000	0.5
Over 200,000 to 700,000	0.4
Over 700,000 to 2,000,000	0.3

$$f = 6.0(N)^{-0.2} \leq 1.0 \quad (1c)$$

where

N = equivalent number of full displacement cycles during the expected service life of the piping system[6]

When the computed stress range varies, whether from thermal expansion or other conditions, S_E is defined as the greatest computed displacement stress range. The value of N in such cases can be calculated by Eq. (1d):

$$N = N_E + \sum(r_i^5 N_i) \text{ for } i = 1, 2, \ldots, n \quad (1d)$$

where

N_E = number of cycles of maximum computed displacement stress range, S_E

r_i = S_i/S_E

S_i = any computed displacement stress range smaller than S_E

N_i = number of cycles associated with displacement stress range S_i

302.3.6 Limits of Calculated Stresses due to Occasional Loads

(a) Operation. The sum of the longitudinal stresses due to pressure, weight, and other sustained loadings S_L and of the stresses produced by occasional loads, such as wind or earthquake, may be as much as 1.33 times the basic allowable stress given in Appendix A. For castings, the basic allowable stress shall be multiplied by the casting quality factor E_c. Where the allowable stress value exceeds two-thirds of yield strength at temperature, the allowable stress value must be reduced as specified in para. 302.3.2(e). Wind and earthquake forces need not be considered as acting concurrently.

[3] For castings, the basic allowable stress shall be multiplied by the applicable casting quality factor E_c. For longitudinal welds, the basic allowable stress need not be multiplied by the weld quality factor E_j.

[4] Applies to essentially noncorroded piping. Corrosion can sharply decrease cyclic life; therefore, corrosion resistant materials should be considered where a large number of major stress cycles is anticipated.

[5] Equation (1c) does not apply beyond approximately 2×10^6 cycles. Selection of f factors beyond 2×10^6 cycles is the designer's responsibility.

[6] The designer is cautioned that the fatigue life of materials operated at elevated temperature may be reduced.

Copyright by the American Society Of Mechanical Engineers

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617527 467 ■

(b) Test. Stresses due to test conditions are not subject to the limitations in para. 302.3. It is not necessary to consider other occasional loads, such as wind and earthquake, as occurring concurrently with test loads.

302.4 Allowances

In determining the minimum required thickness of a piping component, allowances shall be included for corrosion, erosion, and thread depth or groove depth. See definition for c in para. 304.1.1(b).

A00 **302.4.1 Mechanical Strength.** When necessary, the wall thickness shall be increased to prevent overstress, damage, collapse, or buckling due to superimposed loads from supports, ice formation, backfill, transportation, handling, or other causes. Where increasing the thickness would excessively increase local stresses or the risk of brittle fracture, or is otherwise impracticable, the required strength may be obtained through additional supports, braces, or other means without an increased wall thickness. Particular consideration should be given to the mechanical strength of small pipe connections to piping or equipment.

PART 2
PRESSURE DESIGN OF PIPING COMPONENTS

303 GENERAL

Components manufactured in accordance with standards listed in Table 326.1 shall be considered suitable for use at pressure-temperature ratings in accordance with para. 302.2.1. The rules in para. 304 are intended for pressure design of components not covered in Table 326.1, but may be used for a special or more rigorous design of such components. Designs shall be checked for adequacy of mechanical strength under applicable loadings enumerated in para. 301.

304 PRESSURE DESIGN OF COMPONENTS

304.1 Straight Pipe

304.1.1 General

(a) The required thickness of straight sections of pipe shall be determined in accordance with Eq. (2):

$$t_m = t + c \tag{2}$$

The minimum thickness T for the pipe selected, considering manufacturer's minus tolerance, shall be not less than t_m.

(b) The following nomenclature is used in the equations for pressure design of straight pipe.

t_m = minimum required thickness, including mechanical, corrosion, and erosion allowances

t = pressure design thickness, as calculated in accordance with para. 304.1.2 for internal pressure or as determined in accordance with para. 304.1.3 for external pressure

c = the sum of the mechanical allowances (thread or groove depth) plus corrosion and erosion allowances. For threaded components, the nominal thread depth (dimension h of ASME B1.20.1, or equivalent) shall apply. For machined surfaces or grooves where the tolerance is not specified, the tolerance shall be assumed to be 0.5 mm (0.02 in.) in addition to the specified depth of the cut.

T = pipe wall thickness (measured or minimum per purchase specification)

d = inside diameter of pipe. For pressure design calculation, the inside diameter of the pipe is the maximum value allowable under the purchase specification.

P = internal design gage pressure

D = outside diameter of pipe as listed in tables of standards or specifications or as measured

E = quality factor from Table A-1A or A-1B

S = stress value for material from Table A-1

Y = coefficient from Table 304.1.1, valid for $t < D/6$ and for materials shown. The value of Y may be interpolated for intermediate temperatures.

For $t \geq D/6$,

$$Y = \frac{d + 2c}{D + d + 2c}$$

304.1.2 Straight Pipe Under Internal Pressure A00

(a) For $t < D/6$, the internal pressure design thickness for straight pipe shall be not less than that calculated in accordance with either Eq. (3a) or Eq. (3b):

$$t = \frac{PD}{2(SE + PY)} \tag{3a}$$

$$t = \frac{P(d + 2c)}{2[SE - P(1 - Y)]} \tag{3b}$$

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:34 2005

TABLE 304.1.1
VALUES OF COEFFICIENT Y
FOR $t < D/6$

Materials	Temperature, °C (°F) ≤ 482 (900 & Lower)	510 (950)	538 (1000)	566 (1050)	593 (1100)	≥ 621 (1150 & Up)
Ferritic steels	0.4	0.5	0.7	0.7	0.7	0.7
Austenitic steels	0.4	0.4	0.4	0.4	0.5	0.7
Other ductile metals	0.4	0.4	0.4	0.4	0.4	0.4
Cast iron	0.0	...	...	...	...	...

(b) For t ≥ $D/6$ or for $P/SE > 0.385$, calculation of pressure design thickness for straight pipe requires special consideration of factors such as theory of failure, effects of fatigue, and thermal stress.

304.1.3 Straight Pipe Under External Pressure. To determine wall thickness and stiffening requirements for straight pipe under external pressure, the procedure outlined in the BPV Code, Section VIII, Division 1, UG-28 through UG-30 shall be followed, using as the design length L the running center line length between any two sections stiffened in accordance with UG-29. As an exception, for pipe with $D_o/t < 10$, the value of S to be used in determining P_{a2} shall be the lesser of the following values for pipe material at design temperature:

(a) 1.5 times the stress value from Table A-1 of this Code; or

(b) 0.9 times the yield strength tabulated in Section II, Part D, Table Y-1 for materials listed therein.

(The symbol D_o in Section VIII is equivalent to D in this Code.)

304.2 Curved and Mitered Segments of Pipe

A00 **304.2.1 Pipe Bends.** The minimum required thickness t_m of a bend, after bending, in its finished form, shall be determined in accordance with Eq. (2) and Eq. (3c):

$$t = \frac{PD}{2[(SE/I) + PY]} \quad (3c)$$

where at the intrados (inside bend radius)

$$I = \frac{4(R_1/D) - 1}{4(R_1/D) - 2} \quad (3d)$$

and at the extrados (outside bend radius)

$$I = \frac{4(R_1/D) + 1}{4(R_1/D) + 2} \quad (3e)$$

and at the sidewall on the bend centerline radius, $I = 1.0$.

R_1 = bend radius of welding elbow or pipe bend

Thickness variations from the intrados to the extrados and along the length of the bend shall be gradual. The thickness requirements apply at the mid-span of the bend, $\gamma/2$, at the intrados, extrados, and bend centerline radius. The minimum thickness at the end tangents shall not be less than the requirements of para. 304.1 for straight pipe (see Fig. 304.2.1).

304.2.2 Elbows. Manufactured elbows not in accordance with para. 303 shall be qualified as required by para. 304.7.2 or designed in accordance with para. 304.2.1. A00

304.2.3 Miter Bends. An angular offset of 3 deg or less (angle α in Fig. 304.2.3) does not require design consideration as a miter bend. Acceptable methods for pressure design of multiple and single miter bends are given in (a) and (b) below.

(a) Multiple Miter Bends. The maximum allowable internal pressure shall be the lesser value calculated from Eqs. (4a) and (4b). These equations are not applicable when θ exceeds 22.5 deg.

$$P_m = \frac{SE(T-c)}{r_2}\left(\frac{T-c}{(T-c) + 0.643\tan\theta\sqrt{r_2(T-c)}}\right) \quad (4a)$$

$$P_m = \frac{SE(T-c)}{r_2}\left(\frac{R_1 - r_2}{R_1 - 0.5r_2}\right) \quad (4b)$$

(b) Single Miter Bends

(1) The maximum allowable internal pressure for a single miter bend with angle θ not greater than 22.5 deg shall be calculated by Eq. (4a).

(2) The maximum allowable internal pressure for

A00 FIG. 304.2.1 NOMENCLATURE FOR PIPE BENDS

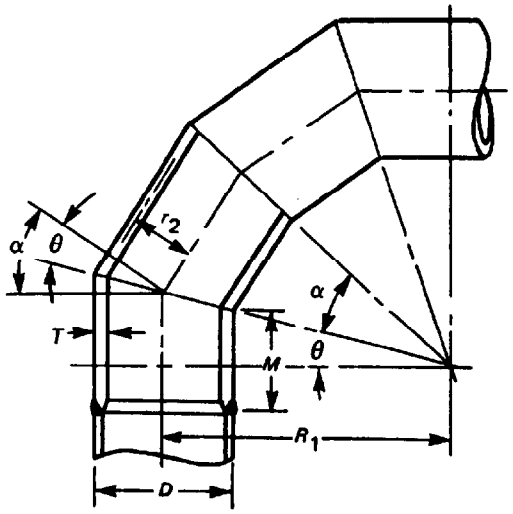

FIG. 304.2.3 NOMENCLATURE FOR MITER BENDS

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:34 2005

a single miter bend with angle θ greater than 22.5 deg shall be calculated by Eq. (4c):

$$P_m = \frac{SE(T-c)}{r_2}\left(\frac{T-c}{(T-c)+1.25\tan\theta\sqrt{r_2(T-c)}}\right) \quad (4c)$$

(c) The miter pipe wall thickness T used in Eqs. (4a), (4b), and (4c) shall extend a distance not less than M from the inside crotch of the end miter welds where

M = the larger of $2.5(r_2T)^{0.5}$ or $\tan\theta\,(R_1 - r_2)$

The length of taper at the end of the miter pipe may be included in the distance M.

(d) The following nomenclature is used in Eqs. (4a), (4b), and (4c) for the pressure design of miter bends:

c = same as defined in para. 304.1.1
E = same as defined in para. 304.1.1
P_m = maximum allowable internal pressure for miter bends
r_2 = mean radius of pipe using nominal wall $\overline{T}$
R_1 = effective radius of miter bend, defined as the shortest distance from the pipe center line to the intersection of the planes of adjacent miter joints
S = same as defined in para. 304.1.1
T = miter pipe wall thickness (measured or minimum per purchase specification)
θ = angle of miter cut
α = angle of change in direction at miter joint = 2θ

For compliance with this Code, the value of R_1 shall be not less than that given by Eq. (5):

$$R_1 = \frac{A}{\tan\theta} + \frac{D}{2} \quad (5)$$

where A has the following empirical values:

(1) for SI metric units:

$(T-c)$, mm	A
≤ 13	25
$13 < (T-c) < 22$	$2(T-c)$
≥ 22	$[2(T-c)/3]+30$

(2) for U.S. customary units:

$(T-c)$, mm	A
≤ 0.5	1.0
$0.5 < (T-c) < 0.88$	$2(T-c)$
≥ 0.88	$[2(T-c)/3]+1.17$

304.2.4 Curved and Mitered Segments of Pipe Under External Pressure. The wall thickness of curved and mitered segments of pipe subjected to external pressure may be determined as specified for straight pipe in para. 304.1.3.

304.3 Branch Connections

304.3.1 General

(a) Except as provided in (b) below, the requirements in paras. 304.3.2 through 304.3.4 are applicable to branch connections made in accordance with the following methods:

(1) fittings (tees, extruded outlets, branch outlet fittings per MSS SP-97, laterals, crosses);

(2) unlisted cast or forged branch connection fittings (see para. 300.2), and couplings not over DN 80 (NPS 3), attached to the run pipe by welding;

(3) welding the branch pipe directly to the run pipe, with or without added reinforcement, as covered in para. 328.5.4.

(b) The rules in paras. 304.3.2 through 304.3.4 are minimum requirements, valid only for branch connections in which (using the nomenclature of Fig. 304.3.3):

(1) the run pipe diameter-to-thickness ratio (D_h/T_h) is less than 100 and the branch-to-run diameter ratio (D_b/D_h) is not greater than 1.0;

(2) for run pipe with $(D_h/T_h) \geq 100$, the branch diameter D_b is less than one-half the run diameter D_h;

(3) angle β is at least 45 deg;

(4) the axis of the branch intersects the axis of the run.

(c) Where the provisions of (a) and (b) above are not met, pressure design shall be qualified as required by para. 304.7.2.

(d) Other design considerations relating to branch connections are stated in para. 304.3.5.

304.3.2 Strength of Branch Connections. A pipe having a branch connection is weakened by the opening that must be made in it and, unless the wall thickness of the pipe is sufficiently in excess of that required to sustain the pressure, it is necessary to provide added reinforcement. The amount of reinforcement required to sustain the pressure shall be determined in accordance with para. 304.3.3 or 304.3.4. There are, however, certain branch connections which have adequate pressure strength or reinforcement as constructed. It may be assumed without calculation that a branch connection has adequate strength to sustain the internal and external pressure which will be applied to it if:

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:34 2005

(a) the branch connection utilizes a listed fitting in accordance with para. 303;

(b) the branch connection is made by welding a threaded or socket welding coupling or half coupling directly to the run in accordance with para. 328.5.4, provided the size of the branch does not exceed DN 50 (NPS 2) nor one-fourth the nominal size of the run. The minimum wall thickness of the coupling anywhere in the reinforcement zone (if threads are in the zone, wall thickness is measured from root of thread to minimum outside diameter) shall be not less than that of the unthreaded branch pipe. In no case shall a coupling or half coupling have a rating less than Class 2000 per ASME B16.11.

(c) the branch connection utilizes an unlisted branch connection fitting (see para. 300.2), provided the fitting is made from materials listed in Table A-1 and provided that the branch connection is qualified as required by para. 304.7.2.

304.3.3 Reinforcement of Welded Branch Connections. Added reinforcement is required to meet the criteria in paras. 304.3.3(b) and (c) when it is not inherent in the components of the branch connection. Sample problems illustrating the calculations for branch reinforcement are shown in Appendix H.

(99) *(a) Nomenclature.* The nomenclature below is used in the pressure design of branch connections. It is illustrated in Fig. 304.3.3, which does not indicate details for construction or welding. Some of the terms defined in Appendix J are subject to further definitions or variations, as follows:

b = subscript referring to branch

d_1 = effective length removed from pipe at branch. For branch intersections where the branch opening is a projection of the branch pipe inside diameter (e.g., pipe-to-pipe fabricated branch), $d_1 = [D_h - 2(T_b - c)]/\sin\beta$

d_2 = "half width" of reinforcement zone
= d_1 or $(T_b - c) + (T_h - c) + d_1/2$, whichever is greater, but in any case not more than D_h

h = subscript referring to run or header

L_4 = height of reinforcement zone outside of run pipe
= $2.5(T_h - c)$ or $2.5(T_b - c) + T_r$, whichever is less

T_b = branch pipe thickness (measured or minimum per purchase specification) except for branch connection fittings (see para. 300.2). For such connections the value of T_b for use in calculating L_4, d_2, and A_3, is the thickness of the reinforcing barrel (minimum per purchase specification) provided that the barrel thickness is uniform (see Fig. K328.5.4) and extends at least to the L_4 limit (see Fig. 304.3.3).

T_r = minimum thickness of reinforcing ring or saddle made from pipe. (Use nominal thickness if made from plate.)
= 0, if there is no reinforcing ring or saddle

t = pressure design thickness of pipe, according to the appropriate wall thickness equation or procedure in para. 304.1. For welded pipe, when the branch does not intersect the longitudinal weld of the run, the basic allowable stress S for the pipe may be used in determining t_h for the purpose of reinforcement calculation only. When the branch does intersect the longitudinal weld of the run, the product SE (of the stress value S and the appropriate weld joint quality factor E_j from Table A-1B) for the run pipe shall be used in the calculation. The product SE of the branch shall be used in calculating t_b.

β = smaller angle between axes of branch and run

(b) Required Reinforcement Area. The reinforcement area A_1 required for a branch connection under internal pressure is

$$A_1 = t_h d_1 (2 - \sin\beta) \quad (6)$$

For a branch connection under external pressure, area A_1 is one-half the area calculated by Eq. (6), using as t_h the thickness required for external pressure.

(c) Available Area. The area available for reinforcement is defined as

$$A_2 + A_3 + A_4 \geq A_1 \quad (6a)$$

These areas are all within the reinforcement zone and are further defined below.

(1) Area A_2 is the area resulting from excess thickness in the run pipe wall:

$$A_2 = (2d_2 - d_1)(T_h - t_h - c) \quad (7)$$

(2) Area A_3 is the area resulting from excess thickness in the branch pipe wall: A00

$$A_3 = 2L_4(T_b - t_b - c)/\sin\beta \quad (8)$$

If the allowable stress for the branch pipe wall is less than that for the run pipe, its calculated area must be reduced in the ratio of allowable stress values of

Copyright by the American Society Of Mechanical Engineers

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617531 998 ■

the branch to the run in determining its contributions to area A_3.

(3) Area A_4 is the area of other metal provided by welds and properly attached reinforcement. [See para. 304.3.3(f).] Weld areas shall be based on the minimum dimensions specified in para. 328.5.4, except

Copyright by the American Society Of Mechanical Engineers

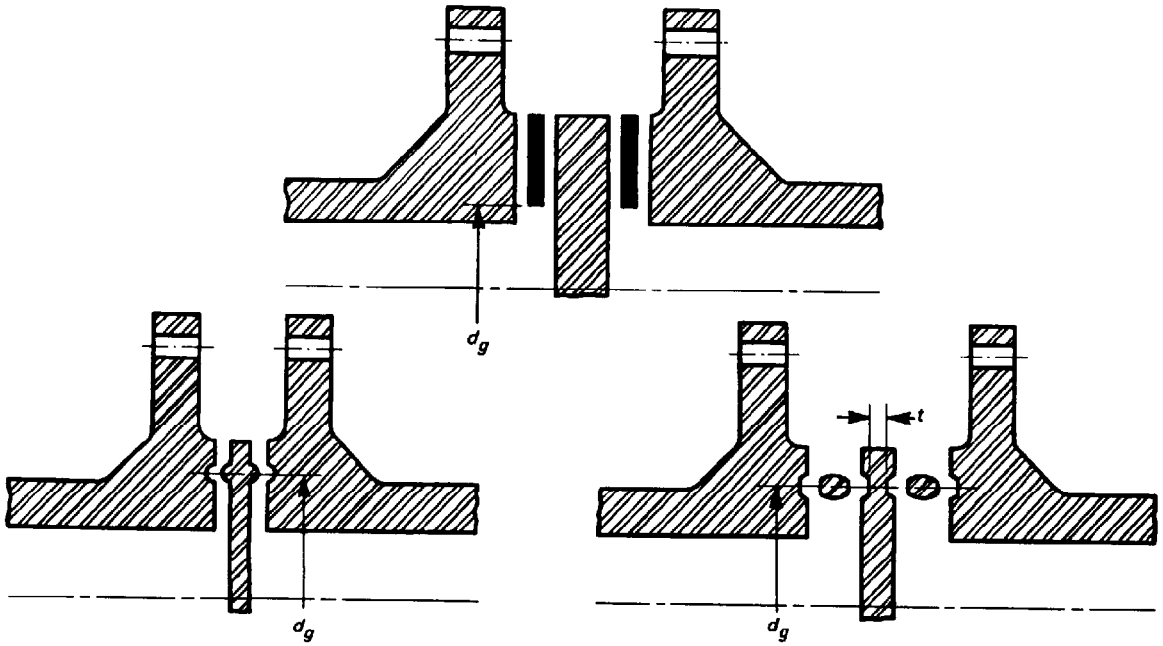

FIG. 304.5.3 BLANKS

paras. 304.7.2(a), (b), (c), or (d), and (e) shall be available for the owner's approval:

(a) extensive, successful service experience under comparable conditions with similarly proportioned components of the same or like material;

(b) experimental stress analysis, such as described in the BPV Code, Section VIII, Division 2, Appendix 6;

(c) proof test in accordance with either ASME B16.9, MSS SP-97, or Section VIII, Division 1, UG-101;

(d) detailed stress analysis (e.g., finite element method) with results evaluated as described in Section VIII, Division 2, Appendix 4, Article 4-1. The basic allowable stress from Table A-1 shall be used in place of S_m in Division 2. At design temperatures in the creep range, additional considerations beyond the scope of Division 2 may be necessary.

(e) For any of the above, the designer may interpolate between sizes, wall thicknesses, and pressure classes, and may determine analogies among related materials.

304.7.3 Metallic Components With Nonmetallic Pressure Parts. Components not covered by standards listed in Table 326.1, in which both metallic and nonmetallic parts contain the pressure, shall be evaluated by applicable requirements of para. A304.7.2 as well as those of para. 304.7.2.

304.7.4 Expansion Joints

(a) Metallic Bellows Expansion Joints. The design of bellows type expansion joints shall be in accordance with Appendix X. See also Appendix F, para. F304.7.4 for further design considerations.

(b) Slip Type Expansion Joints

(1) Pressure containing elements shall be in accordance with para. 318 and other applicable requirements of this Code.

(2) External piping loads shall not impose excessive bending on the joint.

(3) The effective pressure thrust area shall be computed using the outside diameter of the pipe.

(c) Other Types of Expansion Joint. The design of other types of expansion joint shall be qualified as required by para. 304.7.2.

PART 3
FLUID SERVICE REQUIREMENTS FOR PIPING COMPONENTS

305 PIPE

Pipe includes components designated as "tube" or "tubing" in the material specification, when intended for pressure service.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:35 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617533 760 ■

305.1 General

Listed pipe may be used in Normal Fluid Service except as stated in paras. 305.2.1 and 305.2.2. Unlisted pipe may be used only as provided in para. 302.2.3.

305.2 Specific Requirements

305.2.1 Pipe for Category D Fluid Service. The following carbon steel pipe may be used only for Category D Fluid Service:

API 5L, Furnace Butt-Welded
ASTM A 53, Type F
ASTM A 134 made from other than ASTM A 285 plate

305.2.2 Pipe Requiring Safeguarding. When used for other than Category D Fluid Service, the following carbon steel pipe shall be safeguarded:

ASTM A 134 made from ASTM A 285 plate
ASTM A 139

305.2.3 Pipe for Severe Cyclic Conditions. Only the following pipe[7] may be used under severe cyclic conditions:

(a) Carbon Steel Pipe
API 5L, Grade A or B, seamless
API 5L, Grade A or B, SAW, str. seam, $E_j \geq 0.95$
API 5L, Grade X42, seamless
API 5L, Grade X46, seamless
API 5L, Grade X52, seamless
API 5L, Grade X56, seamless
API 5L, Grade X60, seamless
ASTM A 53, seamless
ASTM A 106
ASTM A 333, seamless
ASTM A 369
ASTM A 381, $E_j \geq 0.90$
ASTM A 524
ASTM A 671, $E_j \geq 0.90$
ASTM A 672, $E_j \geq 0.90$
ASTM A 691, $E_j \geq 0.90$

(b) Low and Intermediate Alloy Steel Pipe
ASTM A 333, seamless
ASTM A 335
ASTM A 369
ASTM A 426, $E_c \geq 0.90$
ASTM A 671, $E_j \geq 0.90$
ASTM A 672, $E_j \geq 0.90$
ASTM A 691, $E_j \geq 0.90$

(c) Stainless Steel Alloy Pipe A00
ASTM A 268, seamless
ASTM A 312, seamless
ASTM A 358, $E_j \geq 0.90$
ASTM A 376
ASTM A 451, $E_c \geq 0.90$

(d) Copper and Copper Alloy Pipe
ASTM B 42
ASTM B 466

(e) Nickel and Nickel Alloy Pipe
ASTM B 161
ASTM B 165
ASTM B 167
ASTM B 407

(f) Aluminum Alloy Pipe
ASTM B 210, Tempers 0 and H112
ASTM B 241, Tempers 0 and H112

306 FITTINGS, BENDS, MITERS, LAPS, AND BRANCH CONNECTIONS

Fittings, bends, miters, laps, and branch connections may be used in accordance with paras. 306.1 through 306.5. Pipe and other materials used in such components shall be suitable for the manufacturing or fabrication process and the fluid service.

306.1 Pipe Fittings

306.1.1 Listed Fittings. Listed fittings may be used in Normal Fluid Service in accordance with para. 303.

306.1.2 Unlisted Fittings. Unlisted fittings may be used only in accordance with para. 302.2.3.

306.1.3 Specific Fittings

(a) Proprietary welding branch outlet fittings which (99) have been design proof tested successfully as prescribed in ASME B16.9, MSS SP-97 or the BPV Code, Section VIII, Division 1, UG-101 may be used within their established ratings.

(b) The lap thickness of a proprietary "Type C" lap-joint stub-end buttwelding fitting shall conform to the requirements of para. 306.4.2 for flared laps.

306.1.4 Fittings for Severe Cyclic Conditions

(a) Only the following fittings may be used under severe cyclic conditions:

(1) forged;

(2) wrought, with factor $E_j \geq 0.90$;[8] or

[7] Casting or joint factors E_c or E_j specified for cast or welded pipe which do not correspond with E factors in Table A-1A or A-1B are established in accordance with paras. 302.3.3 and 302.3.4.

[8] See paras. 302.3.3 and 302.3.4.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:36 2005

(3) cast, with factor $E_c \geq 0.90$.[8]

A00 *(b)* Fittings conforming to MSS SP-43, MSS SP-119, and proprietary "Type C" lap-joint stub-end welding fittings shall not be used under severe cyclic conditions.

306.2 Pipe Bends

306.2.1 General. A pipe bend made in accordance with paras. 332.2.1 and 332.2.2, and verified for pressure design in accordance with para. 304.2.1, is suitable for the same service as the pipe from which it is made.

306.2.2 Corrugated and Other Bends. Bends of other designs (such as creased or corrugated) shall be qualified for pressure design as required by para. 304.7.2.

306.2.3 Bends for Severe Cyclic Conditions. A pipe bend designed as creased or corrugated shall not be used under severe cyclic conditions.

306.3 Miter Bends

306.3.1 General. Except as stated in para. 306.3.2, a miter bend made in accordance with para. 304.2.3 and welded in accordance with para. 311.1 is suitable for use in Normal Fluid Service.

306.3.2 Miter Bends for Category D Fluid Service. A miter bend which makes a change in direction at a single joint (angle α in Fig. 304.2.3) greater than 45 deg, or is welded in accordance with para. 311.2.1, may be used only for Category D Fluid Service.

306.3.3 Miter Bends for Severe Cyclic Conditions. A miter bend to be used under severe cyclic conditions shall be made in accordance with para. 304.2.3 and welded in accordance with para. 311.2.2, and shall have an angle α (see Fig. 304.2.3) $\leq$ 22.5 deg.

306.4 Fabricated or Flared Laps

The following requirements do not apply to fittings conforming to para. 306.1, nor to laps integrally hot-forged on pipe ends.

306.4.1 Fabricated Laps. A fabricated lap is suitable for use in Normal Fluid Service, provided that all of the following conditions are met.

(a) The outside diameter of the lap shall be in accordance with the dimension of an ASME B16.9 lap-joint stub end.

(b) The lap thickness shall be at least equal to the nominal wall thickness of the pipe to which it is attached.

(c) The lap material shall be listed in Table A-1 and shall have an allowable stress at least as great as that of the pipe.

(d) Welding shall be in accordance with para. 311.1 and fabrication shall be in accordance with para. 328.5.5.

306.4.2 Flared Laps. A flared lap is suitable for use in Normal Fluid Service, provided that all of the following conditions are met.

(a) The outside diameter of the lap shall be in accordance with the dimension of an ASME B16.9 lap-joint stub end.

(b) The radius of fillet of the flared lap shall not exceed 3 mm ($\frac{1}{8}$ in.), and the backing flange shall meet the requirements of para. 308.2.5.

(c) The lap thickness, measured at any point, shall be at least 95% of the minimum pipe wall thickness T multiplied by the ratio of the pipe outside radius to the radius at which the lap thickness is measured.

(d) Pressure design shall be qualified as required by para. 304.7.2.

306.4.3 Laps for Severe Cyclic Conditions

(a) A fabricated lap to be used under severe cyclic conditions shall conform to the requirements of para. 306.4.1, except that welding shall be in accordance with para. 311.2.2, with fabrication limited to a detail equivalent to Fig. 328.5.5 sketch (d) or (e).

(b) Flared laps shall not be used under severe cyclic conditions.

306.5 Fabricated Branch Connections

The following requirements do not apply to fittings conforming to para. 306.1.

306.5.1 General. A fabricated branch connection made and verified for pressure design in accordance with para. 304.3, and welded in accordance with para. 311.1, is suitable for use in Normal Fluid Service.

306.5.2 Fabricated Branch Connections for Severe Cyclic Conditions. A fabricated branch connection to be used under severe cyclic conditions shall conform to the requirements of para. 306.5.1, except that welding shall be in accordance with para. 311.2.2, with fabrication limited to a detail equivalent to Fig. 328.5.4D sketch (2) or (4), or to Fig. 328.5.4E.

307 VALVES AND SPECIALTY COMPONENTS

The following requirements for valves shall also be met as applicable by other pressure containing piping

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:36 2005

components, such as traps, strainers, and separators. See also Appendix F, paras. F301.4 and F307.

307.1 General

307.1.1 Listed Valves. A listed valve is suitable for use in Normal Fluid Service, except as stated in para. 307.2.

307.1.2 Unlisted Valves. Unlisted valves may be used only in accordance with para. 302.2.3. Unless pressure-temperature ratings are established by the method set forth in Appendix F to ASME B16.34, pressure design shall be qualified as required by para. 304.7.2.

307.2 Specific Requirements

A bolted bonnet valve whose bonnet is secured to the body by less than four bolts, or by a U-bolt, may be used only for Category D Fluid Service.

308 FLANGES, BLANKS, FLANGE FACINGS, AND GASKETS

308.1 General

308.1.1 Listed Components. A listed flange, blank, or gasket is suitable for use in Normal Fluid Service, except as stated elsewhere in para. 308.

308.1.2 Unlisted Components. Unlisted flanges, blanks, and gaskets may be used only in accordance with para. 302.2.3.

(99) ### 308.2 Specific Requirements for Flanges

See Appendix F, paras. F308.2 and F312.

308.2.1 Slip-On Flanges

(a) A slip-on flange shall be double-welded as shown in Fig. 328.5.2B when the service is:

(1) subject to severe erosion, crevice corrosion, or cyclic loading;

(2) flammable, toxic, or damaging to human tissue;

(3) under severe cyclic conditions;

(4) at temperatures below −101°C (−150°F).

(b) The use of slip-on flanges should be avoided where many large temperature cycles are expected, particularly if the flanges are not insulated.

(c) Slip-on Flanges as Lapped Flanges. A slip-on flange may be used as a lapped flange only as shown in Table 308.2.1 unless pressure design is qualified in accordance with para. 304.5.1. A corner radius or bevel shall conform to one of the following as applicable:

(1) for an ASME B16.9 lap joint stub end or a forged lap (see para. 306.4.3) the corner radius shall be as specified in ASME B16.5, Tables 9 and 12, dimension *r*.

(2) for a fabricated lap, the corner bevel shall be at least half the nominal thickness of the pipe to which the lap is attached (see Fig. 328.5.5).

(3) for a flared lap see para. 308.2.5.

TABLE 308.2.1
PERMISSIBLE SIZES/RATING CLASSES FOR SLIP-ON FLANGES USED AS LAPPED FLANGES[1]

Rating		Maximum Flange Size	
PN	Class	DN	NPS
20	150	300	12
50	300	200	8

NOTE:
(1) Actual thickness of flange at bolt circle shall at least equal minimum required flange thickness in ASME B16.5.

308.2.2 Expanded-Joint Flanges. A flange having an expanded-joint insert is subject to the requirements for expanded joints in para. 313.

308.2.3 Socket Welding and Threaded Flanges. A socket welding flange is subject to the requirements for socket welds in para. 311.2.4. A threaded flange is subject to the requirements for threaded joints in para. 314.4.

308.2.4 Flanges for Severe Cyclic Conditions. Unless it is safeguarded, a flange to be used under severe cyclic conditions shall be welding neck conforming to ASME B16.5 or ASME B16.47, or a similarly proportioned flange designed in accordance with para. 304.5.1.

308.2.5 Flanges for Flared Metallic Laps. For a flange used with a flared metallic lap (para. 306.4.2), the intersection of face and bore shall be beveled or rounded approximately 3 mm (⅛ in.). See also para. 308.2.1(c).

STD·ASME B31·3A-ENGL 2000 ■ 0759670 0617536 47T ■

308.3 Flange Facings

The flange facing shall be suitable for the intended service and for the gasket and bolting employed.

308.4 Gaskets

Gaskets shall be selected so that the required seating load is compatible with the flange rating and facing, the strength of the flange, and its bolting. Materials shall be suitable for the service conditions. See also Appendix F, para. F308.4.

309 BOLTING

Bolting includes bolts, bolt studs, studs, cap screws, nuts, and washers. See also Appendix F, para. F309.

309.1 General

309.1.1 Listed Bolting. Listed bolting is suitable for use in Normal Fluid Service, except as stated elsewhere in para. 309.

309.1.2 Unlisted Bolting. Unlisted bolting may be used only in accordance with para. 302.2.3.

309.1.3 Bolting for Components. Bolting for components conforming to a listed standard shall be in accordance with that standard if specified therein.

309.1.4 Selection Criteria. Bolting selected shall be adequate to seat the gasket and maintain joint tightness under all design conditions.

309.2 Specific Bolting

309.2.1 Low Yield Strength Bolting. Bolting having not more than 207 MPa (30 ksi) specified minimum yield strength shall not be used for flanged joints rated ASME B16.5 PN 68 (Class 400) and higher, nor for flanged joints using metallic gaskets, unless calculations have been made showing adequate strength to maintain joint tightness.

309.2.2 Carbon Steel Bolting. Except where limited by other provisions of this Code, carbon steel bolting may be used with nonmetallic gaskets in flanged joints rated ASME B16.5 PN 50 (Class 300) and lower for bolt metal temperatures at −29°C to 204°C (−20°F to 400°F), inclusive. If these bolts are galvanized, heavy hexagon nuts, threaded to suit, shall be used.

A00 **309.2.3 Bolting for Metallic Flange Combinations.** Any bolting which meets the requirements of para. 309 may be used with any combination of flange material and facing. If either flange is to the ASME B16.1, ASME B16.24, MSS SP-42, or MSS SP-51 specification, the bolting material shall be no stronger than low yield strength bolting unless:

(a) both flanges have flat faces and a full face gasket is used; or,

(b) sequence and torque limits for bolt-up are specified, with consideration of sustained loads, displacement strains, and occasional loads (see paras. 302.3.5 and 302.3.6), and strength of the flanges.

309.2.4 Bolting for Severe Cyclic Conditions. Low yield strength bolting (see para. 309.2.1) shall not be used for flanged joints under severe cyclic conditions.

309.3 Tapped Holes

Tapped holes for pressure retaining bolting in metallic piping components shall be of sufficient depth that the thread engagement will be at least seven-eighths times the nominal thread diameter.

PART 4
FLUID SERVICE REQUIREMENTS FOR PIPING JOINTS

310 GENERAL

Piping joints shall be selected to suit the piping material and the fluid service, with consideration of joint tightness and mechanical strength under expected service and test conditions of pressure, temperature, and external loading.

311 WELDED JOINTS

Joints may be made by welding in any material for which it is possible to qualify welding procedures, welders, and welding operators in conformance with the rules in Chapter V.

311.1 General

Except as provided in paras. 311.2.1 and 311.2.2, welds shall conform to the following.

(a) Welding shall be in accordance with para. 328.

(b) Preheating and heat treatment shall be in accordance with paras. 330 and 331, respectively.

(c) Examination shall be in accordance with para. 341.4.1.

(d) Acceptance criteria shall be those in Table 341.3.2 for Normal Fluid Service.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:37 2005

311.2 Specific Requirements

311.2.1 Welds for Category D Fluid Service. Welds which meet the requirements of para. 311.1, but for which examination is in accordance with para. 341.4.2, and acceptance criteria are those in Table 341.3.2 for Category D Fluid Service, may be used only in that service.

311.2.2 Welds for Severe Cyclic Conditions. Welds for use under severe cyclic conditions shall meet the requirements of para. 311.1 with the exceptions that examination shall be in accordance with para. 341.4.3, and acceptance criteria shall be those in Table 341.3.2 for severe cyclic conditions.

311.2.3 Backing Rings and Consumable Inserts

(a) If a backing ring is used where the resulting crevice is detrimental (e.g., subject to corrosion, vibration, or severe cyclic conditions), it should be removed and the internal joint face ground smooth. When it is impractical to remove the backing ring in such a case, consideration shall be given to welding without backing rings or to the use of consumable inserts or removable nonmetallic backing rings.

(b) Split backing rings shall not be used under severe cyclic conditions.

311.2.4 Socket Welds

(a) Socket welded joints (para. 328.5.2) should be avoided in any service where crevice corrosion or severe erosion may occur.

(b) Socket welded joints shall conform to the following.

A00 *(1)* Socket dimensions shall conform to ASME B16.5 for flanges and ASME B16.11 or MSS SP-119 for other socket-welding components.

(2) Weld dimensions shall not be less than those shown in Figs. 328.5.2B and 328.5.2C.

(c) Socket welds larger than DN 50 (NPS 2) shall not be used under severe cyclic conditions.

(d) A drain or bypass in a component may be attached by socket welding, provided the socket dimensions conform to Fig. 4 in ASME B16.5.

311.2.5 Fillet Welds

(a) Fillet welds in accordance with para. 328.5.2 may be used as primary welds to attach socket welding components and slip-on flanges.

(b) Fillet welds may also be used to attach reinforcement and structural attachments, to supplement the strength or reduce stress concentration of primary welds, and to prevent disassembly of joints.

311.2.6 Seal Welds. Seal welds (para. 328.5.3) may be used only to prevent leakage of threaded joints and shall not be considered as contributing any strength to the joints.

312 FLANGED JOINTS

312.1 Joints Using Flanges of Different Ratings

Where flanges of different ratings are bolted together, the rating of the joint shall not exceed that of the lower rated flange. Bolting torque shall be limited so that excessive loads will not be imposed on the lower rated flange in obtaining a tight joint.

312.2 Metal to Nonmetal Flanged Joints

Where a metallic flange is bolted to a nonmetallic flange, both should be flat-faced. A full-faced gasket is preferred. If a gasket extending only to the inner edge of the bolts is used, bolting torque shall be limited so that the nonmetallic flange is not overloaded.

313 EXPANDED JOINTS

(a) Expanded joints shall not be used under severe cyclic conditions. For other services, adequate means shall be provided to prevent separation of the joint. If the fluid is toxic or damaging to human tissue, safeguarding is required.

(b) Consideration shall be given to the tightness of expanded joints when subjected to vibration, differential expansion or contraction due to temperature cycling, or external mechanical loads.

314 THREADED JOINTS

314.1 General

Threaded joints are suitable for Normal Fluid Service except as stated elsewhere in para. 314. They may be used under severe cyclic conditions only as provided in paras. 314.2.1(c) and 314.2.2.

(a) Threaded joints should be avoided in any service where crevice corrosion, severe erosion, or cyclic loading may occur.

(b) When threaded joints are intended to be seal welded, thread sealing compound shall not be used.

(c) Layout of piping employing threaded joints should, insofar as possible, minimize stress on joints, giving special consideration to stresses due to thermal expansion and operation of valves (particularly a valve

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:37 2005

(e) Attachments welded or bonded to the piping shall be of a material compatible with the piping and service. For other requirements, see para. 321.3.2.

321.1.5 Threads. Screw threads shall conform to ANSI B1.1 unless other threads are required for adjustment under heavy loads. Turnbuckles and adjusting nuts shall have the full length of internal threads engaged. Any threaded adjustment shall be provided with a locknut, unless locked by other means.

321.2 Fixtures

321.2.1 Anchors and Guides

(a) A supporting element used as an anchor shall be designed to maintain an essentially fixed position.

(b) To protect terminal equipment or other (weaker) portions of the system, restraints (such as anchors and guides) shall be provided where necessary to control movement or to direct expansion into those portions of the system which are designed to absorb them. The design, arrangement, and location of restraints shall ensure that expansion joint movements occur in the directions for which the joint is designed. In addition to the other thermal forces and moments, the effects of friction in other supports of the system shall be considered in the design of such anchors and guides.

A00 *(c)* Piping layout, anchors, restraints, guides, and supports for all types of expansion joints shall be designed in accordance with para. X301.2 of Appendix X.

321.2.2 Inextensible Supports Other Than Anchors and Guides[10]

(a) Supporting elements shall be designed to permit the free movement of piping caused by thermal expansion and contraction.

(b) Hangers include pipe and beam clamps, clips, brackets, rods, straps, chains, and other devices. They shall be proportioned for all required loads. Safe loads for threaded parts shall be based on the root area of the threads.

(c) Sliding Supports. Sliding supports (or shoes) and brackets shall be designed to resist the forces due to friction in addition to the loads imposed by bearing. The dimensions of the support shall provide for the expected movement of the supported piping.

321.2.3 Resilient Supports[10]

(a) Spring supports shall be designed to exert a supporting force, at the point of attachment to the pipe, equal to the load as determined by weight balance calculations. They shall be provided with means to prevent misalignment, buckling, or eccentric loading of the springs, and to prevent unintentional disengagement of the load.

(b) Constant-support spring hangers provide a substantially uniform supporting force throughout the range of travel. The use of this type of spring hanger is advantageous at locations subject to appreciable movement with thermal changes. Hangers of this type should be selected so that their travel range exceeds expected movements.

(c) Means shall be provided to prevent overstressing spring hangers due to excessive deflections. It is recommended that all spring hangers be provided with position indicators.

321.2.4 Counterweight Supports. Counterweights shall be provided with stops to limit travel. Weights shall be positively secured. Chains, cables, hangers, rocker arms, or other devices used to attach the counterweight load to the piping shall be subject to the requirements of para. 321.2.2.

321.2.5 Hydraulic Supports. An arrangement utilizing a hydraulic cylinder may be used to give a constant supporting force. Safety devices and stops shall be provided to support the load in case of hydraulic failure.

321.3 Structural Attachments

External and internal attachments to piping shall be designed so that they will not cause undue flattening of the pipe, excessive localized bending stresses, or harmful thermal gradients in the pipe wall. It is important that attachments be designed to minimize stress concentration, particularly in cyclic services.

321.3.1 Nonintegral Attachments. Nonintegral attachments, in which the reaction between the piping and the attachment is by contact, include clamps, slings, cradles, U-bolts, saddles, straps, and clevises. If the weight of a vertical pipe is supported by a clamp, it is recommended to prevent slippage that the clamp be located below a flange, fitting, or support lugs welded to the pipe.

321.3.2 Integral Attachments. Integral attachments include plugs, ears, shoes, plates, and angle clips, cast on or welded to the piping. The material for integral attachments attached by welding shall be of good weldable quality. [See para. 321.1.4(e) for material requirements.] Preheating, welding, and heat treatment

[10] Various types of inextensible (solid) and resilient supports are illustrated in MSS SP-58.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:37 2005

shall be in accordance with Chapter V. Consideration shall be given to the localized stresses induced in the piping component by welding the integral attachment.

(a) Integral reinforcement, complete encirclement reinforcement, or intermediate pads of suitable alloy and design may be used to reduce contamination or undesirable heat effects in alloy piping.

(b) Intermediate pads, integral reinforcement, complete encirclement reinforcement, or other means of reinforcement may be used to distribute stresses.

321.4 Structural Connections

The load from piping and pipe supporting elements (including restraints and braces) shall be suitably transmitted to a pressure vessel, building, platform, support structure, foundation, or to other piping capable of bearing the load without deleterious effects.

PART 6
SYSTEMS

322 SPECIFIC PIPING SYSTEMS

322.3 Instrument Piping

322.3.1 Definition. Instrument piping within the scope of this Code includes all piping and piping components used to connect instruments to other piping or equipment, and control piping used to connect air or hydraulically operated control apparatus. It does not include instruments, or permanently sealed fluid-filled tubing systems furnished with instruments as temperature or pressure responsive devices.

322.3.2 Requirements. Instrument piping shall meet the applicable requirements of the Code and the following.

(a) The design pressure and temperature for instrument piping shall be determined in accordance with para. 301. If more severe conditions are experienced during blowdown of the piping, they may be treated as occasional variations in accordance with para. 302.2.4.

(b) Consideration shall be given to the mechanical strength (including fatigue) of small instrument connections to piping or apparatus (see para. 304.3.5).

(c) Instrument piping containing fluids which are normally static and subject to freezing shall be protected by heat tracing or other heating methods, and insulation.

(d) If it will be necessary to blow down (or bleed) instrument piping containing toxic or flammable fluids, consideration shall be given to safe disposal.

322.6 Pressure Relieving Systems

Pressure relieving systems within the scope of this Code shall conform to the following requirements. See also Appendix F, para. F322.6.

322.6.1 Stop Valves in Pressure Relief Piping. If one or more stop valves are installed between the piping being protected and its protective device or devices, or between the protective device or devices and the point of discharge, they shall meet the requirements of (a) and either (b) or (c), below.

(a) A full-area stop valve may be installed on the inlet side of a pressure relieving device. A full area stop valve may be placed on the discharge side of a pressure relieving device when its discharge is connected to a common header with other discharge lines from other pressure relieving devices. Stop valves of less than full area may be used on both the inlet side and discharge side of pressure relieving devices as outlined herein if the stop valves are of such type and size that the increase in pressure drop will not reduce the relieving capacity below that required, nor adversely affect the proper operation of the pressure relieving device.

(b) Stop valves to be used in pressure relief piping shall be so constructed or positively controlled that the closing of the maximum number of block valves possible at one time will not reduce the pressure relieving capacity provided by the unaffected relieving devices below the required relieving capacity.

(c) As an alternative to (b) above, stop valves shall be so constructed and arranged that they can be locked or sealed in either the open or closed position. See Appendix F, para. F322.6.

322.6.2 Pressure Relief Discharge Piping. Discharge lines from pressure relieving safety devices shall be designed to facilitate drainage. When discharging directly to the atmosphere, discharge shall not impinge on other piping or equipment and shall be directed away from platforms and other areas used by personnel. Reactions on the piping system due to actuation of safety relief devices shall be considered, and adequate strength shall be provided to withstand these reactions.

322.6.3 Pressure Relieving Devices

(a) Pressure relieving devices required by para. 301.2.2(a) shall be in accordance with the BPV Code, Section VIII, Division 1, UG-125(c), UG-126 through UG-128, and UG-132 through UG-136, excluding UG-

CHAPTER III
MATERIALS

323 GENERAL REQUIREMENTS

Chapter III states limitations and required qualifications for materials based on their inherent properties. Their use in piping is also subject to requirements and limitations in other parts of this Code [see para. 300(d)]. See also para. 321.1.4 for support materials, and Appendix F, para. F323, for precautionary considerations.

323.1 Materials and Specifications

323.1.1 Listed Materials. Any material used in pressure containing piping components shall conform to a listed specification except as provided in para. 323.1.2.

323.1.2 Unlisted Materials. Unlisted materials may be used provided they conform to a published specification covering chemistry, physical and mechanical properties, method and process of manufacture, heat treatment, and quality control, and otherwise meet the requirements of this Code. Allowable stresses shall be determined in accordance with the applicable allowable stress basis of this Code or a more conservative basis.

323.1.3 Unknown Materials. Materials of unknown specification shall not be used for pressure-containing piping components.

323.1.4 Reclaimed Materials. Reclaimed pipe and other piping components may be used, provided they are properly identified as conforming to a listed or published specification (para. 323.1.1 or 323.1.2) and otherwise meet the requirements of this Code. Sufficient cleaning and inspection shall be made to determine minimum wall thickness and freedom from imperfections which would be unacceptable in the intended service.

323.2 Temperature Limitations

The designer shall verify that materials which meet other requirements of the Code are suitable for service throughout the operating temperature range. Attention is directed to Note (7) in Appendix A, which explains the means used to set both cautionary and restrictive temperature limits in Tables A-1 and A-2.

323.2.1 Upper Temperature Limits, Listed Materials. A listed material may be used at a temperature above the maximum for which a stress value or rating is shown, only if:

(a) there is no prohibition in Appendix A or elsewhere in the Code; and

(b) the designer verifies the serviceability of the material in accordance with para. 323.2.4.

323.2.2 Lower Temperature Limits, Listed Materials A00

(a) A listed material may be used at any temperature not lower than the minimum shown in Table A-1, provided that the base metal, weld deposits, and heat-affected zone (HAZ) are qualified as required by the applicable entry in Column A of Table 323.2.2.

(b) For carbon steels with a letter designation in the Min. Temp. column of Table A-1, the minimum temperature is defined by the applicable curve and Notes in Fig. 323.2.2A. If a design minimum metal temperature-thickness combination is on or above the curve, impact testing is not required.

(c) A listed material may be used at a temperature lower than the minimum shown in Table A-1 or Fig. 323.2.2A (including Notes), unless prohibited in Table 323.2.2, Table A-1, or elsewhere in the Code, and provided that the base metal, weld deposits, and HAZ are qualified as required by the applicable entry in Column B of Table 323.2.2.

(d) Where the Stress Ratio defined in Fig. 323.2.2B is less than one, Fig. 323.2.2B provides a further basis for the use of carbon steels covered by paras. 323.2.2(a) and (b), without impact testing.

(1) For design minimum temperatures of −48°C (−55°F) and above, the minimum design metal temperature without impact testing determined in para. 323.2.2(b), for the given material and thickness, may be reduced by the amount of the temperature reduction provided in Fig. 323.2.2B for the applicable Stress Ratio. If the resulting temperature is lower than the minimum design metal temperature, impact testing of

TABLE 323.2.2
REQUIREMENTS FOR LOW TEMPERATURE TOUGHNESS TESTS FOR METALS
These Toughness Test Requirements Are in Addition to Tests Required by the Material Specification

	Type of Material	Column A Design Minimum Temperature at or Above Min. Temp. in Table A-1 or Fig. 323.2.2A		Column B Design Minimum Temperature Below Min. Temp. in Table A-1 or Fig. 323.2.2A
Listed materials — Materials	1 Gray cast iron	A-1 No additional requirements		B-1 No additional requirements
	2 Malleable and ductile cast iron; carbon steel per Note (1)	A-2 No additional requirements		B-2 Materials designated in Box 2 shall not be used.
		(a) Base Metal	(b) Weld Metal and Heat Affected Zone (HAZ) [Note (2)]	
	3 Other carbon steels; low and intermediate alloy steels; high alloy ferritic steels; duplex stainless steels	A-3 (a) No additional requirements	A-3 (b) Weld metal deposits shall be impact tested per para. 323.3 if design min. temp. < −29°C (−20°F), except as provided in Notes (3) and (5), and except as follows: for materials listed for Curves C and D of Fig. 323.2.2A, where corresponding welding consumables are qualified by impact testing at the design minimum temperature or lower in accordance with the applicable AWS specification, additional testing is not required.	B-3 Except as provided in Notes (3) and (5), heat treat base metal per applicable ASTM specification listed in para. 323.3.2; then impact test base metal, weld deposits, and HAZ per para. 323.3 [see Note (2)]. When materials are used at design min. temp. below the assigned curve as permitted by Notes (2) and (3) of Fig. 323.2.2A, weld deposits and HAZ shall be impact tested [see Note (2)].
	4 Austenitic stainless steels	A-4 (a) If: (1) carbon content by analysis > 0.1%; or (2) material is not in solution heat treated condition; then, impact test per para. 323.3 for design min. temp. < −29°C (−20°F) except as provided in Notes (3) and (6)	A-4 (b) Weld metal deposits shall be impact tested per para. 323.3 if design min. temp. < −29°C (−20°F) except as provided in para. 323.2.2 and in Notes (3) and (6)	B-4 Base metal and weld metal deposits shall be impact tested per para. 323.3. See Notes (2), (3), and (6).
	5 Austenitic ductile iron, ASTM A 571	A-5 (a) No additional requirements	A-5 (b) Welding is not permitted	B-5 Base metal shall be impact tested per para. 323.3. Do not use < −196°C (−320°F). Welding is not permitted.
	6 Aluminum, copper, nickel, and their alloys; unalloyed titanium	A-6 (a) No additional requirements	A-6 (b) No additional requirements unless filler metal composition is outside the range for base metal composition; then test per column B-6	B-6 Designer shall be assured by suitable tests [see Note (4)] that base metal, weld deposits, and HAZ are suitable at the design min. temp.
Unlisted	7 An unlisted material shall conform to a published specification. Where composition, heat treatment, and product form are comparable to those of a listed material, requirements for the corresponding listed material shall be met. Other unlisted materials shall be qualified as required in the applicable section of column B.			

Notes to this Table follow on next page

TABLE 323.2.2 (CONT'D)

NOTES:
(1) Carbon steels conforming to the following are subject to the limitations in Box B-2; plates per ASTM A 36, A 283, and A 570; pipe per ASTM A 134 when made from these plates; and pipe per ASTM A 53 Type F and API 5L Gr. A25 buttweld.
(2) Impact tests that meet the requirements of Table 323.3.1, which are performed as part of the weld procedure qualification, will satisfy all requirements of para. 323.2.2, and need not be repeated for production welds.
(3) Impact testing is not required if the design minimum temperature is below −29°C (−20°F) but at or above −104°C (−155°F) and the Stress Ratio defined in Fig. 323.2.2B does not exceed 0.3 times S.
(4) Tests may include tensile elongation, sharp-notch tensile strength (to be compared with unnotched tensile strength), and/or other tests, conducted at or below design minimum temperature. See also para. 323.3.4.
(5) Impact tests are not required when the maximum obtainable Charpy specimen has a width along the notch of less than 2.5 mm (0.098 in.). Under these conditions, the design minimum temperature shall not be less than the lower of −48°C (−55°F) or the minimum temperature for the material in Table A-1.
(6) Impact tests are not required when the maximum obtainable Charpy specimen has a width along the notch of less than 2.5 mm (0.098 in.).

the material is not required. Where this is applied, the piping system shall also comply with the following requirements:

(a) The piping shall be subjected to a hydrostatic test at no less than 1½ times the design pressure.

(b) Except for piping with a nominal wall thickness of 13 mm (½ in.) or less, the piping system shall be safeguarded (see Appendix G) from external loads such as maintenance loads, impact loads, and thermal shock.

(2) For design minimum temperatures lower than −48°C (−55°F), impact testing is required for all materials, except as provided by Note (3) of Table 323.2.2.

(e) The allowable stress or component rating at any temperature below the minimum shown in Table A-1 or Fig. 323.2.2A shall not exceed the stress value or rating at the minimum temperature in Table A-1 or the component standard.

(f) Impact testing is not required for the following combinations of weld metals and design minimum temperatures:

(1) for austenitic stainless steel base materials having a carbon content not exceeding 0.10%, welded without filler metal, at design minimum temperatures of −101°C (−150°F) and higher.

(2) for austenitic weld metal:

(a) having a carbon content not exceeding 0.10%, and produced with filler metals conforming to AWS A5.4, A5.9, A5.11, A5.14, or A5.22[1] at design minimum temperatures of −101°C (−150°F) and higher; or

(b) having a carbon content exceeding 0.10%, and produced with filler metals conforming to AWS A5.4, A5.9, A5.11, A5.14, or A5.22[1] at design minimum temperatures of −48°C (−55°F) and higher.

323.2.3 Temperature Limits, Unlisted Materials. An unlisted material, acceptable under para. 323.1.2, shall be qualified for service at all temperatures within a stated range, from design minimum temperature to design (maximum) temperature, in accordance with para. 323.2.4.

323.2.4 Verification of Serviceability

(a) When an unlisted material is to be used, or when a listed material is to be used above the highest temperature for which stress values appear in Appendix A, the designer is responsible for demonstrating the validity of the allowable stresses and other limits used in design and of the approach taken in using the material, including the derivation of stress data and the establishment of temperature limits.

(b) Data for the development of design limits shall be obtained from a sound scientific program carried out in accordance with recognized technology for both the material and the intended service conditions. Factors to be considered include:

(1) applicability and reliability of the data, especially for extremes of the temperature range;

(2) resistance of the material to deleterious effects of the fluid service and of the environment throughout the temperature range; and

(3) determination of allowable stresses in accordance with para. 302.3.

323.3 Impact Testing Methods and Acceptance Criteria

323.3.1 General. When impact testing is required by Table 323.2.2, provisions elsewhere in this Code, or the engineering design, it shall be done in accordance

[1] Titles of referenced AWS standards are as follows: AWS A5.4, Stainless Steel Electrodes for Shielded Metal Arc Welding; AWS A5.9, Bare Stainless Steel Welding Electrodes and Rods; AWS A5.11, Nickel and Nickel Alloy Welding Electrodes for Shielded Metal Arc Welding; AWS A5.14, Nickel and Nickel Alloy Bare Welding Electrodes and Rods; and AWS A5.22, Flux Cored Corrosion-Resisting Chromium and Chromium-Nickel Steel Electrodes.

with Table 323.3.1 using the testing methods and acceptance criteria described in paras. 323.3.2 through 323.3.5.

323.3.2 Procedure. Impact testing of each product form of material for any specification (including welds in the components) shall be done using procedures and apparatus in accordance with ASTM A 370, and in conformance with impact testing requirements of the following specifications, except that specific requirements of this Code which conflict with requirements of those specifications shall take precedence.

Product Form	ASTM Spec. No.
Pipe	A 333
Tube	A 334
Fittings	A 420
Forgings	A 350
Castings	A 352
Bolting	A 320
Plate	A 20

GENERAL NOTE: Titles of referenced standards not listed in the Specifications Index for Appendix A are: A 20 General Requirements for Steel Plates for Pressure Vessels and A 370 Test Methods and Definitions for Mechanical Testing of Steel Products.

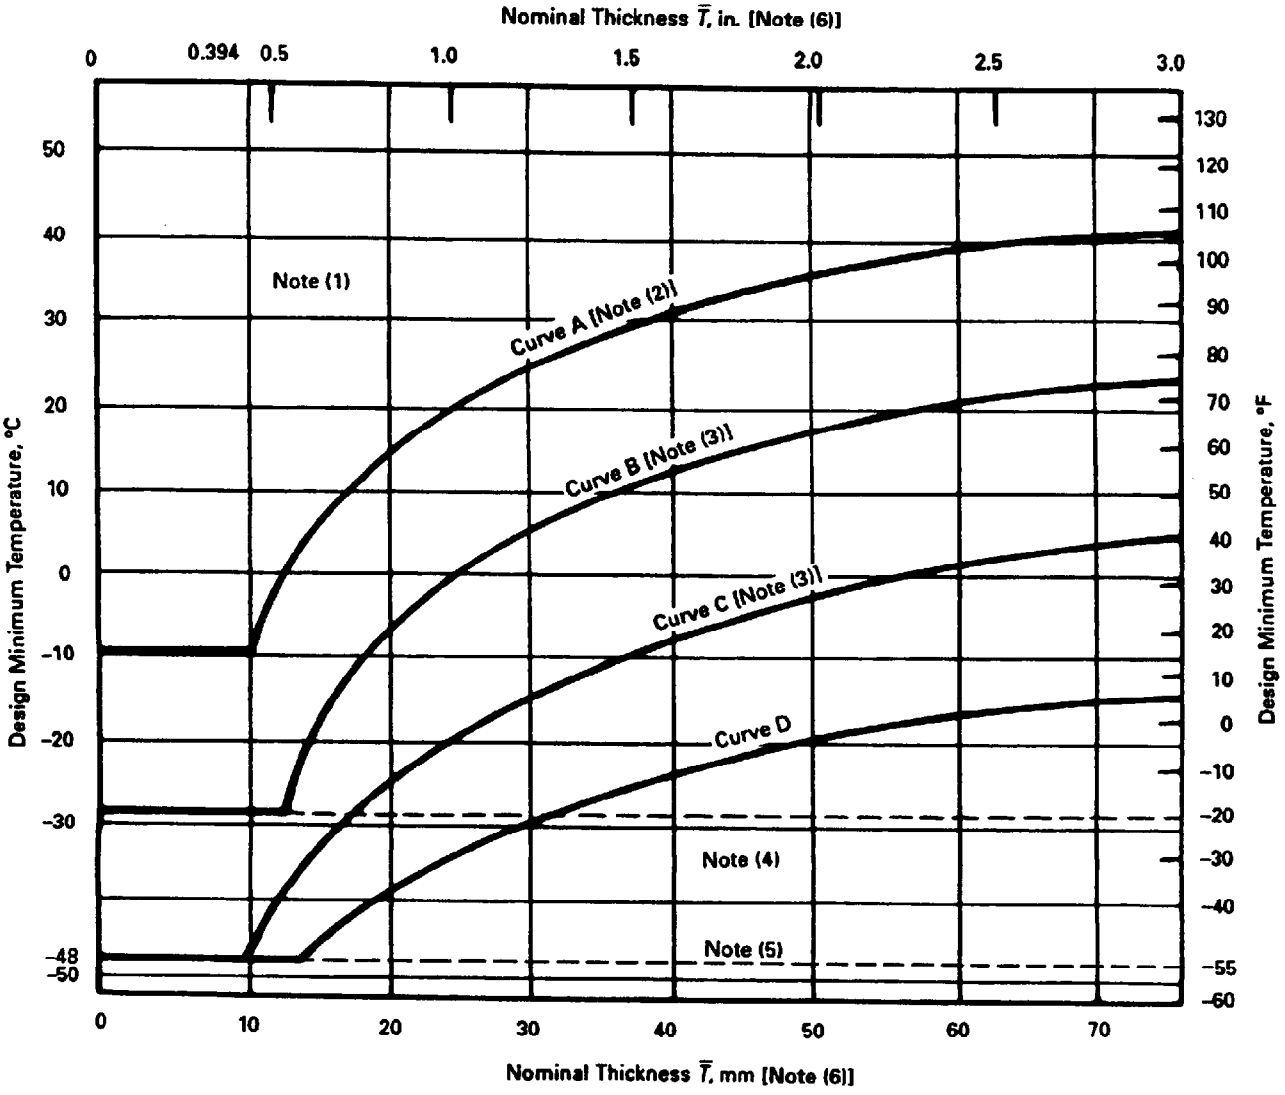
Fig. 323.2.2A



NOTES:
(1) Any carbon steel material may be used to a minimum temperature of -29°C (-20°F) for Category D Fluid Service.
(2) X Grades of API 5L, and ASTM A 381 materials, may be used in accordance with Curve B if normalized or quenched and tempered.
(3) The following materials may be used in accordance with Curve D if normalized:
  (a) ASTM A 516 Plate, all grades;
  (b) ASTM A 671 Pipe, Grades CE55, CE60, and all grades made with A 516 plate;
  (c) ASTM A 672 Pipe, Grades E55, E60, and all grades made with A 516 plate.
(4) A welding procedure for the manufacture of pipe or components shall include impact testing of welds and HAZ for any design minimum temperature below -29°C (-20°F), except as provided in Table 323.2.2, A-3(b).
(5) Impact testing in accordance with para. 323.3 is required for any design minimum temperature below -48°C (-55°F), except as permitted by Note (3) in Table 323.2.2.
(6) For blind flanges and blanks, $\overline{T}$ shall be $^1/_4$ of the flange thickness.

GENERAL NOTES:

(a) The Stress Ratio is defined as the maximum of the following:

(1) nominal pressure stress (based on minimum pipe wall thickness less allowances) divided by S at the design minimum temperature;

(2) for piping components with pressure ratings, the pressure for the condition under consideration divided by the pressure rating at the design minimum temperature;

(3) combined longitudinal stress due to pressure, dead weight, and displacement strain (stress intensification factors are not included in this calculation) divided by S at the design minimum temperature. In calculating longitudinal stress, the forces and moments in the piping system shall be calculated using nominal dimensions and the stresses shall be calculated using section properties based on the nominal dimensions less corrosion, erosion, and mechanical allowances.

(b) Loadings coincident with the metal temperature under consideration shall be used in determining the Stress Ratio as defined above.

CHAPTER IV
STANDARDS FOR PIPING COMPONENTS

326 DIMENSIONS AND RATINGS OF COMPONENTS

326.1 Dimensional Requirements

326.1.1 Listed Piping Components. Dimensional standards[1] for piping components are listed in Table 326.1. Dimensional requirements contained in specifications listed in Appendix A shall also be considered requirements of this Code.

326.1.2 Unlisted Piping Components. Dimensions of piping components not listed in Table 326.1 or Appendix A shall conform to those of comparable listed components insofar as practicable. In any case, dimensions shall be such as to provide strength and performance equivalent to standard components except as provided in paras. 303 and 304.

326.1.3 Threads. The dimensions of piping connection threads not otherwise covered by a governing component standard or specification shall conform to the requirements of applicable standards listed in Table 326.1 or Appendix A.

[1] It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and address of sponsoring organizations, are shown in Appendix E.

326.2 Ratings of Components

326.2.1 Listed Components. The pressure-temperature ratings of components listed in Table 326.1 are accepted for pressure design in accordance with para. 303.

326.2.2 Unlisted Components. The pressure-temperature ratings of unlisted piping components shall conform to the applicable provisions of para. 304.

326.3 Reference Documents

A00

The documents listed in Table 326.1 contain references to codes, standards, and specifications not listed in Table 326.1. Such unlisted codes, standards, and specifications shall be used only in the context of the listed documents in which they appear.

The design, materials, fabrication, assembly, examination, inspection, and testing requirements of this Code are not applicable to components manufactured in accordance with the documents listed in Table 326.1, unless specifically stated in this Code, or the listed document.

TABLE 326.1 (CONT'D)

NOTES:

(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.

(2) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.

(3) This standard allows the use of unlisted materials; see para. 323.1.2.

(4) This standard allows straight pipe threads in sizes ≤ DN 15 (NPS $\frac{1}{2}$); see para. 314.2.1(d).

(5) *Cautionary Note:* Pressure ratings of components manufactured in accordance with editions prior to the 1994 edition of this standard were derated to 80% of equivalent seamless pipe. This derating is no longer required for components manufactured in accordance with the 1994 Edition.

(6) See also Appendix A.

(7) MSS SP-119 includes three classes of fittings: MP, MARINE, and CR. Only the MP class fittings are considered a "Listed Component" for the purpose of this Code. *Cautionary Note:* See MSS SP-119 (Section 6) for special provisions concerning ratings. (In accordance with MSS SP-119, the pressure ratings for MP class fittings are 87.5% of those calculated for straight seamless pipe of *minimum* wall thickness.)

NOTE:
(1) Refer to ASME B16.25 for detailed dimensional information on welding ends.

FIG. 328.3.2 TYPICAL BACKING RINGS AND CONSUMABLE INSERTS

(a) or (b) to correct internal misalignment, such trimming shall not reduce the finished wall thickness below the required minimum wall thickness t_m.

(2) Component ends may be bored to allow for a completely recessed backing ring, provided the remaining net thickness of the finished ends is not less than t_m.

(3) It is permissible to size pipe ends of the same nominal size to improve alignment if wall thickness requirements are maintained.

(4) Where necessary, weld metal may be deposited inside or outside of the component to permit alignment or provide for machining to ensure satisfactory seating of rings or inserts.

(5) When a girth or miter groove weld joins components of unequal wall thickness and one is more than 1½ times the thickness of the other, end preparation and geometry shall be in accordance with acceptable designs for unequal wall thickness in ASME B16.25.

328.4.3 Alignment

(a) Circumferential Welds

(1) Inside surfaces of components at ends to be joined in girth or miter groove welds shall be aligned within the dimensional limits in the WPS and the engineering design.

(2) If the external surfaces of the components are not aligned, the weld shall be tapered between them.

(b) Longitudinal Welds. Alignment of longitudinal groove welds (not made in accordance with a standard listed in Table A-1 or Table 326.1) shall conform to the requirements of para. 328.4.3(a).

(c) Branch Connection Welds

(1) Branch connections which abut the outside surface of the run pipe shall be contoured for groove welds which meet the WPS requirements [see Fig. 328.4.4 sketches (a) and (b)].

(2) Branch connections which are inserted through a run opening shall be inserted at least as far as the inside surface of the run pipe at all points [see Fig. 328.4.4 sketch (c)] and shall otherwise conform to para. 328.4.3(c)(1).

(3) Run openings for branch connections shall not deviate from the required contour more than the dimension m in Fig. 328.4.4. In no case shall deviations

(b) Thicker Pipe Bored for Alignment

FIG. 328.4.3 TRIMMING AND PERMITTED MISALIGNMENT

of the shape of the opening cause the root spacing tolerance limits in the WPS to be exceeded. Weld metal may be added and refinished if necessary for compliance.

(d) Spacing. The root opening of the joint shall be within the tolerance limits in the WPS.

328.5 Welding Requirements

328.5.1 General

(a) Welds, including addition of weld metal for alignment [paras. 328.4.2(b)(4) and 328.4.3(c)(3)], shall be made in accordance with a qualified procedure and by qualified welders or welding operators.

(b) Each qualified welder and welding operator shall be assigned an identification symbol. Unless otherwise specified in the engineering design, each pressure containing weld or adjacent area shall be marked with the identification symbol of the welder or welding operator. In lieu of marking the weld, appropriate records shall be filed.

(c) Tack welds at the root of the joint shall be made with filler metal equivalent to that used in the root pass. Tack welds shall be made by a qualified welder or welding operator. Tack welds shall be fused with the root pass weld, except that those which have cracked shall be removed. Bridge tacks (above the weld) shall be removed.

(d) Peening is prohibited on the root pass and final pass of a weld.

(e) No welding shall be done if there is impingement on the weld area of rain, snow, sleet, or excessive wind, or if the weld area is frosted or wet.

(f) Welding End Valves. The welding sequence and procedure and any heat treatment for a welding end valve shall be such as to preserve the seat tightness of the valve.

328.5.2 Fillet and Socket Welds. Fillet welds (including socket welds) may vary from convex to concave. The size of a fillet weld is determined as shown in Fig. 328.5.2A.

(a) Typical weld details for slip-on and socket welding flanges are shown in Fig. 328.5.2B; minimum welding dimensions for other socket welding components are shown in Fig. 328.5.2C or MSS SP-119. A00

Wed Feb 02 00:57:45 2005

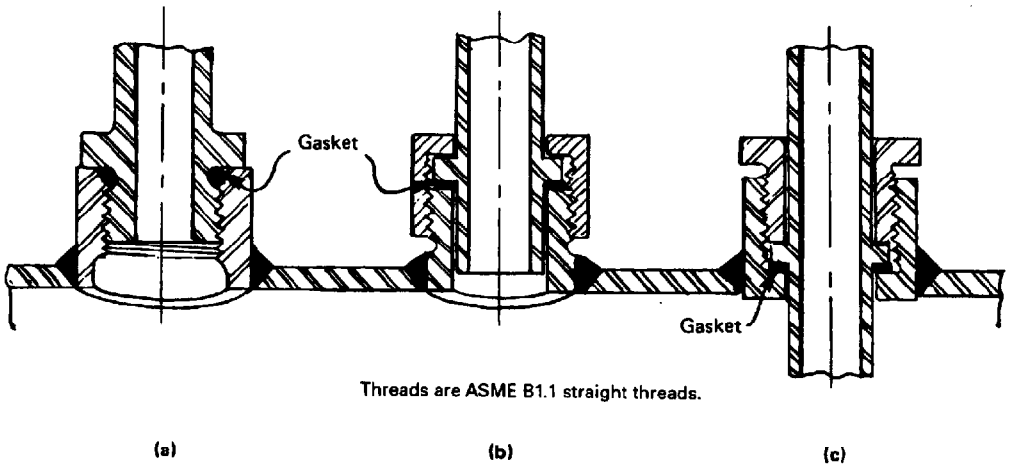

FIG. 335.3.3 TYPICAL THREADED JOINTS USING STRAIGHT THREADS A00

335.2.2 Bolting Torque

(a) In assembling flanged joints, the gasket shall be uniformly compressed to the proper design loading.

(b) Special care shall be used in assembling flanged joints in which the flanges have widely differing mechanical properties. Tightening to a predetermined torque is recommended.

335.2.3 Bolt Length. Bolts should extend completely through their nuts. Any which fail to do so are considered acceptably engaged if the lack of complete engagement is not more than one thread.

335.2.4 Gaskets. No more than one gasket shall be used between contact faces in assembling a flanged joint.

335.3 Threaded Joints

335.3.1 Thread Compound or Lubricant. Any compound or lubricant used on threads shall be suitable for the service conditions and shall not react unfavorably with either the service fluid or the piping material.

335.3.2 Joints for Seal Welding. A threaded joint to be seal welded shall be made up without thread compound. A joint containing thread compound which leaks during leak testing may be seal welded in accordance with para. 328.5.3, provided all compound is removed from exposed threads.

335.3.3 Straight Threaded Joints. Typical joints using straight threads, with sealing at a surface other than the threads, are shown in Fig. 335.3.3 sketches (a), (b), and (c). Care shall be taken to avoid distorting the seat when incorporating such joints into piping assemblies by welding, brazing, or bonding.

335.4 Tubing Joints

335.4.1 Flared Tubing Joints. The sealing surface of the flare shall be examined for imperfections before assembly and any flare having imperfections shall be rejected.

335.4.2 Flareless and Compression Tubing Joints. Where the manufacturer's instructions call for a specified number of turns of the nut, these shall be counted from the point at which the nut becomes finger tight.

335.5 Caulked Joints

Caulked joints shall be installed and assembled in accordance with the manufacturer's instructions, as modified by the engineering design. Care shall be taken to ensure adequate engagement of joint members.

335.6 Expanded Joints and Special Joints

335.6.1 General. Expanded joints and special joints (as defined in para. 318) shall be installed and assembled in accordance with the manufacturer's instructions, as modified by the engineering design. Care shall be taken to ensure adequate engagement of joint members.

335.6.2 Packed Joints. Where a packed joint is used to absorb thermal expansion, proper clearance shall be provided at the bottom of the socket to permit this movement.

335.9 Cleaning of Piping

See Appendix F, para. F335.9.

STD·ASME B31·3A-ENGL 2000 ■ 0759670 0617553 559 ■

(a) date of test
(b) identification of piping system tested
(c) test fluid
(d) test pressure
(e) certification of results by examiner

These records need not be retained after completion of the test if a certification by the Inspector that the piping has satisfactorily passed pressure testing as required by this Code is retained.

345.3 Preparation for Leak Test

345.3.1 Joints Exposed. All joints, including welds and bonds, are to be left uninsulated and exposed for examination during leak testing, except that joints previously tested in accordance with this Code may be insulated or covered. All joints may be primed and painted prior to leak testing unless a sensitive leak test (para. 345.8) is required.

345.3.2 Temporary Supports. Piping designed for vapor or gas shall be provided with additional temporary supports, if necessary, to support the weight of test liquid.

A00 **345.3.3 Piping With Expansion Joints**

(a) An expansion joint that depends on external main anchors to restrain pressure end load shall be tested in place in the piping system.

(b) A self-restrained expansion joint previously shop-tested by the manufacturer [see Appendix X, para. X302.2.3(a)] may be excluded from the system under test, except that such expansion joints shall be installed in the system when a sensitive leak test in accordance with para. 345.8 is required.

(c) A piping system containing expansion joints shall be leak tested without temporary joint or anchor restraint at the lesser of:

(1) 150 % of design pressure for a bellows-type expansion joint; or

(2) the system test pressure determined in accordance with para. 345.

In no case shall a bellows-type expansion joint be subjected to a test pressure greater than the manufacturer's test pressure.

(d) When a system leak test at a pressure greater than the minimum test pressure specified in (c), or greater than 150% of the design pressure within the limitations of para. 345.2.1(a) is required, bellows-type expansion joints shall be removed from the piping system or temporary restraints shall be added to limit main anchor loads if necessary.

345.3.4 Limits of Tested Piping. Equipment which is not to be tested shall be either disconnected from the piping or isolated by blinds or other means during the test. A valve may be used provided the valve (including its closure mechanism) is suitable for the test pressure.

345.4 Hydrostatic Leak Test

345.4.1 Test Fluid. The fluid shall be water unless there is the possibility of damage due to freezing or to adverse effects of water on the piping or the process. In that case another suitable nontoxic liquid may be used. If the liquid is flammable, its flash point shall be at least 49°C (120°F), and consideration shall be given to the test environment.

345.4.2 Test Pressure. Except as provided in para. 345.4.3, the hydrostatic test pressure at any point in a metallic piping system shall be as follows:

(a) not less than $1\frac{1}{2}$ times the design pressure;

(b) for design temperature above the test temperature, the minimum test pressure shall be calculated by Eq. (24), except that the value of S_T/S shall not exceed 6.5:

$$P_T = \frac{1.5\ PS_T}{S} \qquad (24)$$

where

P_T = minimum test gage pressure
P = internal design gage pressure
S_T = stress value at test temperature
S = stress value at design temperature (see Table A-1)

(c) if the test pressure as defined above would produce a nominal pressure stress or longitudinal stress in excess of the yield strength at test temperature, the test pressure may be reduced to the maximum pressure that will not exceed the yield strength at test temperature. [See paras. 302.3.2(e) and (f).] For metallic bellows expansion joints, see Appendix X, para. X302.2.3(a).

345.4.3 Hydrostatic Test of Piping With Vessels[4] as a System

(a) Where the test pressure of piping attached to a vessel is the same as or less than the test pressure for the vessel, the piping may be tested with the vessel at the piping test pressure.

[4] The provisions of para. 345.4.3 do not affect the pressure test requirements of any applicable vessel code.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:46 2005

(b) Where the test pressure of the piping exceeds the vessel test pressure, and it is not considered practicable to isolate the piping from the vessel, the piping and the vessel may be tested together at the vessel test pressure, provided the owner approves and the vessel test pressure is not less than 77% of the piping test pressure calculated in accordance with para. 345.4.2(b).

345.5 Pneumatic Leak Test

345.5.1 Precautions. Pneumatic testing involves the hazard of released energy stored in compressed gas. Particular care must therefore be taken to minimize the chance of brittle failure during a pneumatic leak

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:46 2005

test. Test temperature is important in this regard and must be considered when the designer chooses the material of construction. See para. 345.2.2(c) and Appendix F, para. F323.4.

345.5.2 Pressure Relief Device. A pressure relief device shall be provided, having a set pressure not higher than the test pressure plus the lesser of 345 kPa (50 psi) or 10% of the test pressure.

345.5.3 Test Fluid. The gas used as test fluid, if not air, shall be nonflammable and nontoxic.

345.5.4 Test Pressure. The test pressure shall be 110% of design pressure.

345.5.5 Procedure. The pressure shall be gradually increased until a gage pressure which is the lesser of one-half the test pressure or 170 kPa (25 psi) is attained, at which time a preliminary check shall be made, including examination of joints in accordance with para. 341.4.1(a). Thereafter, the pressure shall be gradually increased in steps until the test pressure is reached, holding the pressure at each step long enough to equalize piping strains. The pressure shall then be reduced to the design pressure before examining for leakage in accordance with para. 345.2.2(a).

345.6 Hydrostatic-Pneumatic Leak Test

If a combination hydrostatic-pneumatic leak test is used, the requirements of para. 345.5 shall be met, and the pressure in the liquid filled part of the piping shall not exceed the limits stated in para. 345.4.2.

345.7 Initial Service Leak Test

This test is applicable only to piping in Category D Fluid Service, at the owner's option. See para. 345.1(a).

345.7.1 Test Fluid. The test fluid is the service fluid.

345.7.2 Procedure. During or prior to initial operation, the pressure shall be gradually increased in steps until the operating pressure is reached, holding the pressure at each step long enough to equalize piping strains. A preliminary check shall be made as described in para. 345.5.5 if the service fluid is a gas or vapor.

345.7.3 Examination for Leaks. In lieu of para. 345.2.2(a), it is permissible to omit examination for leakage of any joints and connections previously tested in accordance with this Code.

345.8 Sensitive Leak Test

The test shall be in accordance with the Gas and Bubble Test method specified in the BPV Code, Section V, Article 10, or by another method demonstrated to have equal sensitivity. Sensitivity of the test shall be not less than 10^{-3} atm·ml/sec under test conditions.

(a) The test pressure shall be at least the lesser of 105 kPa (15 psi) gage, or 25% or the design pressure.

(b) The pressure shall be gradually increased until a gage pressure the lesser of one-half the test pressure or 170 kPa (25 psi) is attained, at which time a preliminary check shall be made. Then the pressure shall be gradually increased in steps until the test pressure is reached, the pressure being held long enough at each step to equalize piping strains.

345.9 Alternative Leak Test

The following procedures and leak test method may be used only under the conditions stated in para. 345.1(c).

345.9.1 Examination of Welds. Welds, including those used in the manufacture of welded pipe and fittings, which have not been subjected to hydrostatic or pneumatic leak tests in accordance with this Code, shall be examined as follows.

(a) Circumferential, longitudinal, and spiral groove welds shall be 100% radiographed in accordance with para. 344.5.

(b) All welds, including structural attachment welds, not covered in (a) above, shall be examined using the liquid penetrant method (para. 344.4) or, for magnetic materials, the magnetic particle method (para. 344.3).

345.9.2 Flexibility Analysis. A flexibility analysis of the piping system shall have been made in accordance with the requirements of para. 319.4.2 (b), if applicable, or (c) and (d).

345.9.3 Test Method. The system shall be subjected to a sensitive leak test in accordance with para. 345.8.

346 RECORDS

346.2 Responsibility

It is the responsibility of the piping designer, the manufacturer, the fabricator, and the erector, as applicable, to prepare the records required by this Code and by the engineering design.

PART 8
PIPING COMPONENTS, STANDARDS

A326 DIMENSIONS AND RATINGS OF COMPONENTS

A326.1 Requirements

Paragraph 326 applies in its entirety except that references to Table A326.1 and Appendix B replace references to Table 326.1 and Appendix A, respectively.

A00 **A326.4 Abbreviations in Table A326.1 and Appendix B**

The abbreviations tabulated below are used in this Chapter to replace lengthy phrases in the text and in the titles of standards in Table A326.1 and the Specifications Index for Appendix B. Those marked with an asterisk (*) are in accordance with ASTM D 1600, Terminology Relating to Abbreviations, Acronyms, and Codes for Terms Relating to Plastics.

Abbreviation	Term
*ABS	Acrylonitrile-Butadiene-Styrene
*CAB	Cellulose Acetate-Butyrate
CP	Chlorinated Polyether
*CPVC	Chlorinated Poly (Vinyl Chloride)
ECTFE	Ethylene-Chlorotrifluoroethylene
ETFE	Ethylene-Tetrafluoroethylene
*FEP	Perfluoro (Ethylene-Propylene) copolymer
PB	Polybutylene
*PE	Polyethylene
PFA	Perfluoro (Alkoxyalkane) copolymer
*POM	Polyacetal, Poly (Oxymethylene)
POP	Poly (Phenylene Oxide)
*PP	Polypropylene
*PPS	Poly (Phenylene Sulfide)
PR	Pressure Rated
*PTFE	Polytetrafluoroethylene
*PVC	Poly (Vinyl Chloride)
*PVDC	Poly (Vinylidene Chloride)
*PVDF	Poly (Vinylidene Fluoride)
RPM	Reinforced Plastic Mortar
RTR	Reinforced Thermosetting Resin
SDR	Standard Dimensional Ratio

PART 9
FABRICATION, ASSEMBLY, AND ERECTION

A327 GENERAL

Piping materials and components are prepared for assembly and erection by one or more of the fabrication processes in paras. A328, A329, A332, and A334. When any of these processes is used in assembly and erection, requirements are the same as for fabrication.

A328 BONDING OF PLASTICS

Paragraph A328 applies only to joints in thermoplastic, RTR, and RPM piping. Bonding shall conform to paras. A328.1 through A328.7 and the applicable requirements of para. A311.

A328.1 Bonding Responsibility

Each employer is responsible for the bonding done by personnel of his organization and, except as provided in paras. A328.2.2 and A328.2.3, shall conduct the required performance qualification tests to qualify bonding procedure specifications (BPS) and bonders or bonding operators.

A328.2 Bonding Qualifications

A328.2.1 Qualification Requirements

(a) Qualification of the BPS to be used, and of the performance of bonders and bonding operators, is required. To qualify a BPS, all tests and examinations specified therein and in para. A328.2.5 shall be completed successfully.

(b) In addition to the procedure for making the bonds, the BPS shall specify at least the following:

(1) all materials and supplies (including storage requirements);

(2) tools and fixtures (including proper care and handling);

(3) environmental requirements (e.g., temperature, humidity, and methods of measurement);

(4) joint preparation;

(5) dimensional requirements and tolerances;

(6) cure time;

(7) protection of work;

(8) tests and examinations other than those required by para. A328.2.5; and

(9) acceptance criteria for the completed test assembly.

A328.2.2 Procedure Qualification by Others. Subject to the specific approval of the Inspector, a BPS qualified by others may be used provided that:

(a) the Inspector satisfies himself that the proposed qualified BPS has been prepared and executed by a responsible recognized organization with expertise in the field of bonding;

NOTES:
(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.
(2) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.
(3) The term *fiberglass RTR* takes the place of the ASTM designation: "*fiberglass*" (*glass-fiber-reinforced thermosetting resin*).
(4) This Standard allows the use of unlisted materials; see para. 323.1.2.
(5) This Standard contains no pressure-temperature ratings.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:48 2005

(b) by signature, the employer accepts both the BPS and procedure qualification record (PQR) as his own; and

(c) the employer has at least one currently employed bonder who, while in his employ, has satisfactorily passed a performance qualification test using the proposed qualified BPS.

A328.2.3 Performance Qualification by Others. Without the Inspector's specific approval, an employer shall not accept a performance qualification test made by a bonder or bonding operator for another employer. If approval is given, it is limited to work on piping using the same or equivalent BPS. An employer accepting such performance qualification tests shall obtain a copy of the performance qualification test record from the previous employer showing the name of the employer by whom the bonder or bonding operator was qualified, the date of such qualification, and the date the bonder or bonding operator last bonded pressure piping under such performance qualification.

A328.2.4 Qualification Records. The employer shall maintain a self-certified record, available to the owner or owner's agent and to the Inspector, of the BPS used and the bonders or bonding operators employed by him, and showing the dates and results of BPS qualifications and bonding performance qualifications.

A328.2.5 Qualification Tests. Tests, as specified in para. A328.2.1(a), shall be performed to qualify each BPS and the performance of each bonder and bonding operator. Test assemblies shall conform to (a) below and the test method shall be in accordance with either (b) or (c).

(a) Test Assembly. The assembly shall be fabricated in one pipe size in accordance with the BPS and shall contain at least one of each different type of joint identified in the BPS. More than one test assembly may be prepared if necessary to accommodate all of the joint types or to assure that at least one of each joint type is loaded in both circumferential and longitudinal directions. The size of pipe and fittings in the assembly shall be as follows.

(1) When the largest size to be joined is 110 mm (NPS 4) or smaller, the test assembly shall be the largest size to be joined.

(2) When the largest size to be joined is greater than 110 mm, the size of the test assembly shall be either 110 mm or 25% of the largest piping size to be joined, whichever is greater.

(b) Burst Test Method. The test assembly shall be subjected to a burst test in accordance with the applicable sections of ASTM D 1599.[5] The time to burst in this standard may be extended. The test is successful if failure initiates outside of any bonded joint.

(c) Hydrostatic Test Method. The test assembly shall be subjected to hydrostatic pressure of at least P_T for not less than 1 hr with no leakage or separation of joints.

(1) For thermoplastics, P_T shall be determined in accordance with Eq. (27):

$$P_T = 0.80\overline{T}\left(\frac{(S_S + S_H)}{D - \overline{T}}\right) \quad (27)$$

where

D = outside diameter of pipe
$\overline{T}$ = nominal thickness of pipe
S_S = mean short term burst stress in accordance with ASTM D 1599,[5] from Table B-1 if listed, otherwise from manufacturer's data.
S_H = mean long term hydrostatic strength (LTHS) in accordance with ASTM D 2837. Use twice the 23°C (73°F) HDB design stress from Table B-1 if listed; or use manufacturer's data.

(2) For RTR (laminated and filament-wound) and RPM, P_T shall be three times the manufacturer's allowable pressure for the components being joined.

(3) The test shall be conducted so that the joint is loaded in both the circumferential and longitudinal directions.

A328.2.6 Performance Requalification. Renewal of a bonding performance qualification is required when:

(a) a bonder or bonding operator has not used the specific bonding process for a period of 6 months or more; or (99) A00

(b) there is specific reason to question the individual's ability to make bonds that meet the BPS.

A328.3 Bonding Materials and Equipment

A328.3.1 Materials. Bonding materials that have deteriorated by exposure to air or prolonged storage, or will not spread smoothly, shall not be used in making joints.

A328.3.2 Equipment. Fixtures and tools used in making joints shall be in such condition as to perform their functions satisfactorily.

[5] Titles of referenced standards and specifications are listed in Table A326.1, except ASTM D 1599 and ASTM D 2855, Practice for Making Solvent-Cemented Joints with PVC Pipe and Fittings.

CHAPTER VIII
PIPING FOR CATEGORY M FLUID SERVICE

M300 GENERAL STATEMENTS

(a) Chapter VIII pertains to piping designated by the owner as being in Category M Fluid Service. See also Appendix M.

(b) The organization, content, and paragraph designations of this Chapter correspond to those of the base Code (Chapters I through VI) and Chapter VII. The prefix M is used.

(c) Provisions and requirements of the base Code and Chapter VII apply only as stated in this Chapter.

(d) Consideration shall be given to the possible need for engineered safeguards (see Appendix G, para. G300.3) in addition to the safeguards already provided (paras. G300.1 and G300.2).

(e) This Chapter makes no provision for piping to be used under severe cyclic conditions. The occurrence of such conditions can ordinarily be circumvented by piping layout, component selection, and other means. If this is not feasible, the engineering design shall specify any necessary provisions in accordance with para. 300(c)(5).

(f) Chapter I applies in its entirety.

PART 1
CONDITIONS AND CRITERIA

M301 DESIGN CONDITIONS

Paragraph 301 applies in its entirety, with the exceptions of paras. 301.3 and 301.5. See paras. M301.3 and M301.5.

M301.3 Design Temperature, Metallic Piping

Use of any temperature other than the fluid temperature as the design temperature shall be substantiated by heat transfer calculations confirmed by tests or by experimental measurements.

M301.5 Dynamic Effects

Paragraph 301.5 applies with the exception of paras. 301.5.1 and 301.5.4. See paras. M301.5.1 and M301.5.4.

M301.5.1 Impact. Design, layout, and operation of piping shall be conducted so as to minimize impact and shock loads. In the event that such loadings are unavoidable, para. 301.5.1 applies.

M301.5.4 Vibration. Suitable dynamic analysis, such as computer simulation, shall be made where necessary to avoid or minimize conditions which lead to detrimental vibration, pulsation, or resonance effects in the piping.

M302 DESIGN CRITERIA

M302.1 General

Paragraph M302 pertains to pressure-temperature ratings, stress criteria, design allowances, and minimum design values, together with permissible variations of these factors as applied to piping design.

Paragraph 302 applies in its entirety, with the exception of paras. 302.2 and 302.3. See paras. M302.2 and M302.3.

M302.2 Pressure-Temperature Design Criteria

Paragraph 302.2 applies in its entirety, with the exception of paras. 302.2.4 and 302.2.5. See paras. M302.2.4 and M302.2.5.

M302.2.4 Allowance for Pressure and Temperature Variations, Metallic Piping. Use of allowances in para. 302.2.4 is not permitted. Design temperature and pressure shall be based on coincident pressure-temperature conditions requiring the greatest wall thickness or the highest component rating.

M302.2.5 Ratings at Junction of Different Services, Metallic Piping. When two services that operate at different pressure-temperature conditions are connected, the valve segregating the services shall be rated for the more severe service condition.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:50 2005

M302.3 Allowable Stresses and Other Stress Limits for Metallic Piping

Paragraph 302.3 applies in its entirety, with the exception of para. 302.3.2. See para. M302.3.2.

M302.3.2 Bases for Allowable Stresses. The designer shall fully document the basis for using any stress limit not in accordance with the stress Tables in Appendix A.

M302.4 Allowances

Paragraph 302.4 applies in its entirety.

PART 2
PRESSURE DESIGN OF METALLIC PIPING COMPONENTS

M303 GENERAL

Paragraph 303 applies in its entirety.

M304 PRESSURE DESIGN OF METALLIC COMPONENTS

Paragraph 304 applies in its entirety.

PART 3
FLUID SERVICE REQUIREMENTS FOR METALLIC PIPING COMPONENTS

M305 PIPE

M305.1 General

Listed pipe may be used in accordance with para. M305.2. Unlisted pipe may be used only as provided in para. 302.2.3.

M305.2 Specific Requirements for Metallic Pipe

Pipe listed in para. 305.2.2 shall not be used. The provision for severe cyclic conditions in para. 305.2.3 does not apply [see para. M300(e)].

M306 METALLIC FITTINGS, BENDS, MITERS, LAPS, AND BRANCH CONNECTIONS

General. Fittings, bends, miters, laps, and branch connections may be used in accordance with paras. M306.1 through M306.6. Pipe and other materials used in such components shall be suitable for the manufacturing process and the fluid service.

M306.1 Pipe Fittings

Paragraph 306.1 applies in its entirety, with the exception of para. 306.1.3. See para. M306.1.3 below. The provision for severe cyclic conditions in para. 306.1.4 does not apply [see para. M300(e)].

M306.1.3 Specific Fittings. The following shall not be used:

(a) fittings conforming to MSS SP-43 and MSS SP-119; A00

(b) proprietary "Type C" lap-joint stub-end butt welding fittings.

M306.2 Pipe Bends

Paragraph 306.2 applies, except that bends in accordance with para. 306.2.2 shall not be used and para. 306.2.3 does not apply [see para. M300(e)].

M306.3 Miter Bends

A miter bend shall conform to para. 306.3.1 and shall not make a change in direction at a single joint (angle α in Fig. 304.2.3) greater than 22.5 deg. Paragraph 306.3.3 does not apply [see para. M300(e)].

M306.4 Fabricated or Flared Laps

M306.4.1 General. The following requirements do not apply to fittings conforming to para. M306.1, nor to laps integrally forged on pipe ends. Paragraph 306.4.1 applies.

M306.4.2 Flared Laps. A flared lap shall meet the requirements of para. 306.4.2. In addition:

(a) pipe size shall be $\leq$ DN 100 (NPS 4), with wall thickness before flaring $\geq$ the value of T for Schedule 10S;

(b) pressure-temperature rating shall be $\leq$ that of an ASME B16.5 PN 20 (Class 150) Group 1.1 flange; and

(c) service temperature shall be $\leq$ 204°C (400°F).

M306.5 Fabricated Branch Connections

The following requirements do not apply to fittings conforming to para. M306.1. Paragraph 306.5.1 applies, with the following exceptions.

(a) Of the methods listed in para. 304.3.1(a), the one in subpara. (3) may be used only if those in (1) and (2) are unavailable.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:50 2005

(b) Of the branch connections described in paras. 304.3.2(b) and (c), those having threaded outlets are permitted only in accordance with para. M314 and those having socket welding outlets are permitted only in accordance with para. M311.2.

M306.6 Closures

The following requirements do not apply to blind flanges or to fittings conforming to para. M306.1. Of the closures described in para. 304.4, flat closures in accordance with the BPV Code, Section VIII, Division 1, UG-34 and UW-13, and conical closures without transition knuckles [UG-32(g) and UG-33(f)], may be used only if others are not available. The requirements in M306.5 apply to openings in closures [see also para. 304.4.2(b)].

M307 METALLIC VALVES AND SPECIALTY COMPONENTS

The following requirements for valves shall also be met as applicable by other pressure containing piping components, such as strainers and separators. See also Appendix F, para. F307.

M307.1 General

Paragraph 307.1 applies, subject to the requirements in para. M307.2.

M307.2 Specific Requirements

(a) Valves having threaded bonnet joints (other than union joints) shall not be used.

(b) Only metallic valves conforming to the following requirements may be used.

(1) Special consideration shall be given to valve design to prevent stem leakage to the environment.

(2) Bonnet or cover plate closures shall be: flanged, secured by at least four bolts with gasketing conforming to para. 308.4; or proprietary, attached by bolts, lugs, or other substantial means, and having a gasket design that increases gasket compression as fluid pressure increases; or secured with a full penetration weld made in accordance with para. M311; or secured by a straight thread sufficient for mechanical strength, a metal-to-metal seat, and a seal weld made in accordance with para. M311, all acting in series.

(3) Body joints, other than bonnet or cover plate joints, shall conform to para. M307.2(b)(2).

M308 FLANGES, BLANKS, FLANGE FACINGS, AND GASKETS

Paragraph 308.1 applies in its entirety.

M308.2 Specific Requirements for Metallic Flanges

Paragraph 308.2.4 does not apply [see para. M300(e)]. The following shall not be used:

(a) single-welded slip-on flanges;

(b) expanded-joint flanges; A00

(c) slip-on flanges used as lapped flanges unless the requirements in para. 308.2.1(c) are met;

(d) threaded metallic flanges, except those employing lens rings or similar gaskets and those used in lined pipe where the liner extends over the gasket face.

M308.3 Flange Facings

Paragraph 308.3 applies.

M308.4 Gaskets

Paragraph 308.4 applies.

M308.5 Blanks

All blanks shall be marked with material, rating, and size.

M309 BOLTING

Paragraph 309 applies, except for para. 309.2.4 [see para. M300(e)].

PART 4
FLUID SERVICE REQUIREMENTS FOR METALLIC PIPING JOINTS

M310 METALLIC PIPING, GENERAL

Paragraph 310 applies in its entirety.

M311 WELDED JOINTS IN METALLIC PIPING

Welded joints may be made in any metal for which it is possible to qualify welding procedures, welders, and welding operators in accordance with para. M328.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:51 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617563 4T8 ■

M311.1 General

Paragraph 311.1 applies with the following exceptions.

(a) Split backing rings shall not be used.

(b) Socket welded joints greater than DN 50 (NPS 2) are not permitted.

(c) Examination shall be in accordance with para. M341.4.

M311.2 Specific Requirements

Paragraphs 311.2.3(a), 311.2.4(a), (b), and (d), 311.2.5, and 311.2.6 apply.

M312 FLANGED JOINTS IN METALLIC PIPING

Paragraph 312 applies in its entirety.

M313 EXPANDED JOINTS IN METALLIC PIPING

Expanded joints shall not be used.

M314 THREADED JOINTS IN METALLIC PIPING

M314.1 General

Paragraphs 314.1(a), (b), and (c) apply.

M314.2 Specific Requirements

M314.2.1 Taper-Threaded Joints. Paragraph 314.2.1 applies except that only components suitable for Normal Fluid Service in sizes 8 ≤ DN ≤ 25 (¼ ≤ NPS ≤ 1) are permitted (see Table 314.2.1). Sizes smaller than DN 20 (NPS ¾) shall be safeguarded (see Appendix G).

A00 **M314.2.2 Straight-Threaded Joints.** Paragraph 314.2.2 applies. In addition, components shall have adequate mechanical strength and the joint shall have a confined seating surface not subject to relative rotation as or after the joint is tightened. [See Fig. 335.3.3 sketches (b) and (c) for acceptable construction.]

M315 TUBING JOINTS IN METALLIC PIPING

Paragraph 315 applies, except for para. 315.2(b).

M316 CAULKED JOINTS

Caulked joints shall not be used.

M317 SOLDERED AND BRAZED JOINTS

Soldered, brazed, and braze welded joints shall not be used.

M318 SPECIAL JOINTS IN METALLIC PIPING

Paragraph 318 applies, with the exception that adhesive joints and bell type joints shall not be used.

PART 5
FLEXIBILITY AND SUPPORT OF METALLIC PIPING

M319 FLEXIBILITY OF METALLIC PIPING

Paragraph 319 applies, with the exception that the simplified rules in para. 319.4.1(c) do not apply.

M321 PIPING SUPPORT

Paragraph 321 applies, except that supporting elements shall be of listed material.

PART 6
SYSTEMS

M322 SPECIFIC PIPING SYSTEMS

M322.3 Instrument Piping

Paragraph 322.3 applies, with the exception that, for signal lines in contact with process fluids and process temperature–pressure conditions:

(a) tubing shall be not larger than 16 mm (⅝ in.) O.D. and shall be suitable for the service; A00

(b) an accessible block valve shall be provided to isolate the tubing from the pipeline;

(c) joining methods shall conform to the requirements of paras. 315.1 and 315.2.

Copyright by the American Society Of Mechanical Engineers

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617564 334 ■

M322.6 Pressure Relieving Systems

Paragraph 322.6 applies, except for para. 322.6.3. See para. M322.6.3.

M322.6.3 Overpressure Protection. For metallic piping, the design pressure may be exceeded by no more than 10% during operation of a pressure relieving system.

PART 7
METALLIC MATERIALS

M323 GENERAL REQUIREMENTS

M323.1 Materials and Specifications

Paragraphs 323.1.1 and 323.1.2 apply. See paras. M323.1.3 and M323.1.4.

M323.1.3 Unknown Materials. Materials of unknown specification shall not be used.

M323.1.4 Reclaimed Metallic Materials. Reclaimed materials may be used when the material certification records are available for the specific materials employed, and the designer is assured that the material is sound and free from harmful defects.

M323.2 Temperature Limitations

Paragraph 323.2 applies with the exception that, in regard to lower temperature limits, the relaxation of minimum temperature limits stated in Note (3) of Table 323.2.2 is not permitted.

M323.3 Impact Testing Methods and Acceptance Criteria

Paragraph 323.3 applies in its entirety.

M323.4 Fluid Service Requirements for Metallic Materials

Paragraph 323.4.1 applies.

M323.4.2 Specific Requirements. Paragraph 323.4.2 applies, except that cast irons other than ductile iron shall not be used for pressure-containing parts, and lead and tin shall be used only as linings.

M323.4.3 Metallic Cladding and Lining Materials. In addition to the requirements of para. 323.4.3, where materials covered in paras. 323.4.2(c)(2) and 323.4.3 are used as cladding or lining in which the cladding or lining also serves as a gasket or as part of the flange facing, consideration shall be given to the design of the flanged joint to prevent leakage to the environment.

M323.5 Deterioration of Materials in Service

Paragraph 323.5 applies in its entirety.

M325 MATERIALS — MISCELLANEOUS

M325.1 Joining and Auxiliary Materials

In applying para. 325, materials such as solvents, brazes, and solders shall not be used. Nonmetallic materials used as gaskets and packing materials shall be suitable for the fluid service.

PART 8
STANDARDS FOR PIPING COMPONENTS

M326 DIMENSIONS AND RATINGS OF COMPONENTS

Paragraph 326.1.3 applies.

M326.1 Dimensional Requirements

M326.1.1 Listed Piping Components. Except for prohibitions and restrictions stated elsewhere in Chapter VIII, components made in accordance with standards and specifications listed in Table 326.1 may be used in Category M service.

M326.1.2 Unlisted Piping Components. Dimensions of unlisted components shall be governed by requirements in paras. 303 and 304.

M326.2 Ratings of Components

Paragraph 326.2 applies in its entirety.

M326.3 Reference Documents A00

Paragraph 326.3 applies in its entirety.

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617565 270 ■

PART 9
FABRICATION, ASSEMBLY, AND ERECTION OF METALLIC PIPING

M327 GENERAL

Metallic piping materials and components are prepared for assembly and erection by one or more of the fabrication processes in paras. M328, M330, M331,

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:53 2005

and M332. When any of these processes is used in assembly and erection, requirements are the same as for fabrication.

M328 WELDING OF METALS

Welding shall be in accordance with paras. M311.1 and 328, except see para. M328.3.

M328.3 Welding Materials

Paragraph 328.3 applies in its entirety, except that split backing rings shall not be used, and removable backing rings and consumable inserts may be used only where their suitability has been demonstrated by procedure qualification.

M330 PREHEATING OF METALS

Paragraph 330 applies in its entirety.

M331 HEAT TREATMENT OF METALS

Paragraph 331 applies in its entirety, with the exception that no requirements less stringent than those of Table 331.1.1 shall be specified.

M332 BENDING AND FORMING OF METALS

Paragraph 332 applies in its entirety, except that bending which conforms to para. 332.2.3 is not permitted.

M335 ASSEMBLY AND ERECTION OF METALLIC PIPING

M335.1 General

M335.1.1 Alignment. In addition to the requirements of para. 335.1.1, any bending or forming required for alignment and fit-up shall be heat treated if required by para. 332.4.

M335.2 Flanged Joints

Paragraph 335.2 applies in its entirety.

M335.3 Threaded Joints

Paragraphs 335.3.1 and 335.3.2 apply. See paras. M335.3.3 and M335.3.4.

M335.3.3 Straight-Threaded Joints. The requirements of para. 335.3.3 are subject to the limitations in para. M322.

M335.3.4 Condition of Threads. Taper-threaded components and threaded ends permitted under para. M314.2.1 shall be examined before assembly for cleanliness and continuity of threads and shall be rejected if not in conformance with ASME B1.20.1 or other applicable standards.

M335.4 Tubing Joints

M335.4.1 Flared Tubing Joints. The requirements of para. 335.4.1 apply; however, see para. M322 for limitations associated with specific piping systems. (99)

M335.4.2 Flareless and Compression Tubing Joints. The requirements of para. 335.4.2 apply; however, see para. M322 for limitations associated with specific piping systems. (99)

M335.6 Special Joints

Special joints shall be in accordance with paras. M318 and 335.6.1.

M335.9 Cleaning of Piping

See Appendix F, para. F335.9.

PART 10
INSPECTION, EXAMINATION, TESTING, AND RECORDS OF METALLIC PIPING

M340 INSPECTION

Paragraph 340 applies in its entirety.

M341 EXAMINATION

Paragraphs 341.1, 341.2, 341.3, and 341.5 apply in their entirety. See para. M341.4.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:53 2005

CHAPTER IX
HIGH PRESSURE PIPING

K300 GENERAL STATEMENTS

(a) Applicability. This Chapter pertains to piping designated by the owner as being in High Pressure Fluid Service. Its requirements are to be applied in full to piping so designated. High pressure is considered herein to be pressure in excess of that allowed by the ASME B16.5 PN 420 (Class 2500) rating for the specified design temperature and material group. However, there are no specified pressure limitations for the application of these rules.

(b) Responsibilities. In addition to the responsibilities stated in para. 300(b):

(1) for each piping system designated as being in High Pressure Fluid Service, the owner shall provide all information necessary to perform the analyses and testing required by this Chapter;

(2) the designer shall make a written report to the owner summarizing the design calculations and certifying that the design has been performed in accordance with this Chapter.

(c) The identification, intent, and Code requirements in paras. 300(a), (c), (d), (e), and (f) apply.

(d) The organization, content, and, wherever possible, paragraph designations of this Chapter correspond to those of the first six Chapters (the base Code). The prefix K is used.

(e) Provisions and requirements of the base Code apply only as stated in this Chapter.

K300.1 Scope

K300.1.1 Content and Coverage. Paragraph 300.1.1 applies with the exceptions stated in paras. K300.1.3 and K300.1.4.

K300.1.2 Packaged Equipment Piping. Interconnecting piping as described in para. 300.1.2 shall conform to the requirements of this Chapter.

K300.1.3 Exclusions. In addition to the exclusions stated in para. 300.1.3, this Chapter excludes nonmetallic and nonmetallic-lined piping.

K300.1.4 Category M Fluid Service. This Chapter makes no provision for piping in Category M Fluid Service. If such piping is required by the owner, the engineering design shall be developed as provided in para. 300(c)(5).

K300.2 Definitions

Paragraph 300.2 applies except for terms relating only to nonmetals and severe cyclic conditions.

The term allowable stress is used in lieu of basic allowable stress.

The term safeguarding and other terms characterizing hazardous fluid services are not used in this Chapter but should be taken into account in design.

K300.3 Nomenclature

Paragraph 300.3 applies.

K300.4 Status of Appendices A00

Paragraph 300.4 and Table 300.4 apply, except for Appendices A, B, H, L, V, and X.

PART 1
CONDITIONS AND CRITERIA

K301 DESIGN CONDITIONS

Paragraph 301 applies with the exceptions of paras. 301.1, 301.2, 301.3, and 301.5.

K301.1 General

Paragraph 301.1 applies but refer to para. K301 instead of para. 301.

K301.2 Design Pressure

K301.2.1 General. Paragraph 301.2.1(a) applies except that reference to para. 302.2.4 is not applicable. Paragraphs 301.2.1(b) and (c) apply, but refer to para. K304 instead of para. 304.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:54 2005

K301.2.2 Required Pressure Containment or Relief. Paragraphs 301.2.2(a) and (b) apply, but refer to para. K322.6.3 instead of para. 322.6.3. Paragraph 301.2.2(c) is not applicable.

K301.3 Design Temperature

Paragraph 301.3 applies with the exceptions of paras. 301.3.1 and 301.3.2 and the following exceptions in the text.

(a) Refer to para. K301.2 instead of para. 301.2.

(b) Refer to para. K301.3.2 instead of para. 301.3.2.

K301.3.1 Design Minimum Temperature. Paragraph 301.3.1 applies, but refer to para. K323.2.2 instead of para. 323.2.2.

K301.3.2 Uninsulated Components. The fluid temperature shall be used as the component temperature.

K301.5 Dynamic Effects

Paragraph 301.5 applies with the exception of para. 301.5.4.

K301.5.4 Vibration. Suitable dynamic analysis shall be made where necessary, to avoid or minimize conditions which lead to detrimental vibration, pulsation, or resonance effects in the piping.

K302 DESIGN CRITERIA

K302.1 General

In para. K302, pressure-temperature ratings, stress criteria, design allowances, and minimum design values are stated, and permissible variations of these factors as applied to design of high pressure piping systems are formulated.

The designer shall be satisfied as to the adequacy of the design, and of materials and their manufacture, considering at least the following:

(a) tensile, compressive, flexural, and shear strength at design temperature;

(b) fatigue strength;

(c) design stress and its basis;

(d) ductility and toughness;

(e) possible deterioration of mechanical properties in service;

(f) thermal properties;

(g) temperature limits;

(h) resistance to corrosion and erosion;

(i) fabrication methods;

(j) examination and testing methods;

(k) hydrostatic test conditions; and

(l) bore imperfections.

K302.2 Pressure-Temperature Design Criteria

K302.2.1 Listed Components Having Established Ratings. Pressure-temperature ratings for certain piping components have been established and are contained in some of the standards in Table K326.1. Unless limited elsewhere in this Chapter, those ratings are acceptable for design pressures and temperatures under this Chapter. With the owner's approval, the rules and limits of this Chapter may be used to extend the pressure-temperature ratings of a component beyond the ratings of the listed standard, but not beyond the limits stated in para. K323.2.

K302.2.2 Listed Components Not Having Specific Ratings

(a) Piping components for which design stresses have been developed in accordance with para. K302.3, but which do not have specific pressure-temperature ratings, shall be rated by rules for pressure design in para. K304, within the range of temperatures for which stresses are shown in Table K-1, modified as applicable by other rules of this Chapter.

(b) Piping components which do not have allowable stresses or pressure-temperature ratings shall be qualified for pressure design as required by para. K304.7.2.

K302.2.3 Unlisted Components

(a) Piping components not listed in Table K326.1 or Table K-1, but which conform to a published specification or standard, may be used subject to the following requirements:

(1) the designer shall determine that composition, mechanical properties, method of manufacture, and quality control are comparable to the corresponding characteristics of listed components; and

(2) pressure design shall be verified in accordance with para. K304, including the fatigue analysis required by para. K304.8.

(b) Other unlisted components shall be qualified for pressure design as required by para. K304.7.2.

K302.2.4 Allowance for Pressure and Temperature Variations. Variations in pressure above the design pressure at the coincident temperature, except for accumulation during pressure relieving (see para. K322.6.3), are not permitted for any piping system.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:54 2005

quality factor E_c = 1.00, with examination and acceptance criteria in accordance with para. K302.3.3. All welds shall have a weld quality factor E_j = 1.00, with examination and acceptance criteria in accordance with paras. K341 through K344. Listed fittings may be used in accordance with para. K303. Unlisted fittings may be used only in accordance with para. K302.2.3.

K306.1.2 Specific Fittings

(a) Socket welding fittings are not permitted.

(b) Threaded fittings are permitted only in accordance with para. K314.

(c) Branch connection fittings (see para. 300.2) whose design has been performance tested successfully as required by para. K304.7.2(b) may be used within their established ratings.

K306.2 Pipe Bends

K306.2.1 General. A bend made in accordance with para. K332.2 and verified for pressure design in accordance with para. K304.2.1 shall be suitable for the same service as the pipe from which it is made.

K306.2.2 Corrugated and Other Bends. Bends of other design (such as creased or corrugated) are not permitted.

K306.3 Miter Bends

Miter bends are not permitted.

K306.4 Fabricated or Flared Laps

Only forged laps are permitted.

K306.5 Fabricated Branch Connections

Fabricated branch connections constructed by welding shall be fabricated in accordance with para. K328.5.4 and examined in accordance with para. K341.4.

K307 VALVES AND SPECIALTY COMPONENTS

The following requirements for valves shall also be met, as applicable, by other pressure containing piping components, such as traps, strainers, and separators.

K307.1 General

Pressure design of unlisted valves shall be qualified as required by para. K304.7.2.

K308 FLANGES, BLANKS, FLANGE FACINGS, AND GASKETS

K308.1 General

Pressure design of unlisted flanges shall be verified in accordance with para. K304.5.1 or qualified as required by para. K304.7.2.

K308.2 Specific Flanges

K308.2.1 Threaded Flanges. Threaded flanges may be used only within the limitations on threaded joints in para. K314.

K308.2.2 Other Flange Types. Slip-on, socket welding, and expanded joint flanges, and flanges for flared laps, are not permitted.

K308.3 Flange Facings

The flange facing shall be suitable for the service and for the gasket and bolting employed.

K308.4 Gaskets

Gaskets shall be selected so that the required seating load is compatible with the flange rating and facing, the strength of the flange, and its bolting. Materials shall be suitable for the service conditions. Mode of gasket failure shall be considered in gasket selection and joint design.

K308.5 Blanks

Blanks shall have a marking identifying material, pressure-temperature rating, and size, which is visible after installation.

K309 BOLTING

Bolting, including bolts, bolt studs, studs, cap screws, nuts, and washers, shall meet the requirements of the BPV Code, Section VIII, Division 2, Article M-5. See also Appendix F, para. F309, of this Code.

PART 4
FLUID SERVICE REQUIREMENTS FOR PIPING JOINTS

K310 GENERAL

Joints shall be suitable for the fluid handled, and for the pressure-temperature and other mechanical loadings expected in service.

K311 WELDED JOINTS

K311.1 General

Welds shall conform to the following.

(a) Welding shall be in accordance with para. K328.

(b) Preheating and heat treatment shall be in accordance with paras. K330 and K331, respectively.

(c) Examination shall be in accordance with para. K341.4, with acceptance criteria as shown in Table K341.3.2.

K311.2 Specific Requirements

K311.2.1 Backing Rings and Consumable Inserts. Backing rings shall not be used. Consumable inserts shall not be used in butt welded joints except when specified by the engineering design.

K311.2.2 Fillet Welds. Fillet welds may be used only for structural attachments in accordance with the requirements of paras. K321 and K328.5.2.

K311.2.3 Other Weld Types. Socket welds and seal welds are not permitted.

K312 FLANGED JOINTS

Flanged joints shall be selected for leak tightness, considering the requirements of para. K308, flange facing finish, and method of attachment. See also para. F312.

K312.1 Joints Using Flanges of Different Ratings

Paragraph 312.1 applies.

K313 EXPANDED JOINTS

Expanded joints are not permitted.

K314 THREADED JOINTS

K314.1 General

Except as provided in paras. K314.2 and K314.3, threaded joints are not permitted as pipeline assembly joints.

(a) Layout of piping should be such as to minimize strain on threaded joints which could adversely affect sealing.

(b) Supports shall be designed to control or minimize strain and vibration on threaded joints and seals.

K314.2 Special Threaded Joints

Special threaded joints may be used to attach flanges or fittings for joints in which the pipe end projects through the flange or fitting and is machined to form the sealing surface with a lens ring, cone ring, the mating pipe end, or other similar sealing device.

K314.3 Other Threaded Joints

Threaded joints not in accordance with para. K314.2 shall be used only for instrumentation, vents, drains, and similar purposes, and shall be not larger than DN 15 (NPS ½). Such joints shall not be subject to bending or vibration loads.

K314.3.1 Taper-Threaded Joints. For mechanical strength, male-threaded components shall be at least Schedule 160 in nominal wall thickness. The nominal thickness of Schedule 160 piping is listed in ASME B36.10M for DN 15 (NPS ½) and in ASME B16.11 for sizes smaller than DN 15 (NPS ½). A00

K314.3.2 Straight-Threaded Joints. Threaded joints in which the tightness of the joint is provided by a seating surface other than the threads (e.g., construction shown in Fig. 335.3.3) shall be qualified as required by para. K304.7.2.

K315 TUBING JOINTS

Tubing joints of the flared, flareless, and compression type are not permitted.

K316 CAULKED JOINTS

Caulked joints are not permitted.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:56 2005

K317 SOLDERED AND BRAZED JOINTS

K317.1 Soldered Joints

Soldered joints are not permitted.

K317.2 Brazed Joints

(a) Braze welded joints and fillet joints made with brazing filler metal are not permitted.

(b) Brazed joints shall be made in accordance with para. K333 and shall be qualified as required by para. K304.7.2. Such application is the owner's responsibility. The melting point of brazing alloys shall be considered when exposure to fire is possible.

K318 SPECIAL JOINTS

Special joints include coupling, mechanical, and gland nut and collar types of joints.

K318.1 General

Joints may be used in accordance with para. 318.2 and the requirements for materials and components in this Chapter.

K318.2 Specific Requirements

K318.2.1 Prototype Tests. A prototype joint shall have been subjected to performance tests in accordance with para. K304.7.2(b) to determine the safety of the joint under test conditions simulating all expected service conditions. Testing shall include cyclic simulation.

K318.2.2 Prohibited Joints. Bell type and adhesive joints are not permitted.

PART 5
FLEXIBILITY AND SUPPORT

K319 FLEXIBILITY

Flexibility analysis shall be performed for each piping system. Paragraphs 319.1 through 319.7 apply, except for paras. 319.4.1(c) and 319.4.5. The computed displacement stress range shall be within the allowable displacement stress range in para. K302.3.5 and shall also be included in the fatigue analysis in accordance with para. K304.8.

K321 PIPING SUPPORT

Piping supports and methods of attachment shall be in accordance with para. 321 except as modified below, and shall be detailed in the engineering design.

K321.1.1 Objectives. Paragraph 321.1.1 applies, but substitute "Chapter" for "Code" in (1).

K321.1.4 Materials. Paragraph 321.1.4 applies, but replace (e) with the following:

(e) Attachments welded to the piping shall be of a material compatible with the piping and the service. Other requirements are specified in paras. K321.3.2 and K323.4.2(b).

K321.3.2 Integral Attachments. Paragraph 321.3.2 applies, but substitute "K321.1.4(e)" for "321.1.4(e)" and "Chapter IX" for "Chapter V."

PART 6
SYSTEMS

K322 SPECIFIC PIPING SYSTEMS

K322.3 Instrument Piping

K322.3.1 Definition. Instrument piping within the scope of this Chapter includes all piping and piping components used to connect instruments to high pressure piping or equipment. Instruments, permanently sealed fluid-filled tubing systems furnished with instruments as temperature- or pressure-responsive devices, and control piping for air or hydraulically operated control apparatus (not connected directly to the high pressure piping or equipment) are not within the scope of this Chapter.

K322.3.2 Requirements. Instrument piping within the scope of this Chapter shall be in accordance with para. 322.3.2 except that the design pressure and temperature shall be determined in accordance with para. K301, and the requirements of para. K310 shall apply. Instruments, and control piping not within the scope of this Chapter, shall be designed in accordance with para. 322.3.

K322.6 Pressure Relieving Systems

Paragraph 322.6 applies, except for para. 322.6.3.

K322.6.3 Overpressure Protection. Overpressure protection for high pressure piping systems shall conform to the following.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:56 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617572 400 ■

(a) The cumulative capacity of the pressure relieving devices shall be sufficient to prevent the pressure from rising more than 10% above the piping design pressure at the operating temperature during the relieving condition for a single relieving device or more than 16% above the design pressure when more than one device is provided, except as provided in (c) below.

(b) System protection must include one relief device set at or below the design pressure at the operating temperature for the relieving condition, with no device set to operate at a pressure greater than 105% of the design pressure, except as provided in (c) below.

(c) Supplementary pressure relieving devices provided for protection against overpressure due to fire or other unexpected sources of external heat shall be set to operate at a pressure not greater than 110% of the design pressure of the piping system and shall be capable of limiting the maximum pressure during relief to no more than 121% of the design pressure.

PART 7
MATERIALS

K323 GENERAL REQUIREMENTS

(a) Paragraph K323 states limitations and required qualifications for materials based on their inherent properties. Their use is also subject to requirements elsewhere in Chapter IX and in Table K-1.

(b) Specific attention should be given to the manufacturing process to ensure uniformity of properties throughout each piping component.

(c) See para. K321.1.4 for support materials.

K323.1 Materials and Specifications

K323.1.1 Listed Materials. Any material used in a pressure-containing piping component shall conform to a listed specification, except as provided in para. K323.1.2.

K323.1.2 Unlisted Materials. An unlisted material may be used, provided it conforms to a published specification covering chemistry, physical and mechanical properties, method and process of manufacture, heat treatment, and quality control, and otherwise meets the requirements of this Chapter. Allowable stresses shall be determined in accordance with the applicable allowable stress basis of this Chapter or a more conservative basis.

K323.1.3 Unknown Materials. Materials of unknown specification, type, or grade are not permitted.

K323.1.4 Reclaimed Materials. Reclaimed pipe and other piping components may be used provided they are properly identified as conforming to a listed specification, have documented service history for the material and fatigue life evaluation, and otherwise meet the requirements of this Chapter. Sufficient cleaning and inspection shall be made to determine minimum wall thickness and freedom from defects which would be unacceptable in the intended service.

K323.1.5 Product Analysis. Conformance of materials to the product analysis chemical requirements of the applicable specification shall be verified, and certification shall be supplied. Requirements for product analysis are defined in the applicable materials specification.

K323.1.6 Repair of Materials by Welding. A material defect may be repaired by welding, provided that all of the following criteria are met.

(a) The material specification provides for weld repair.

(b) The welding procedure and welders or welding operators are qualified as required by para. K328.2.

(c) The repair and its examination are performed in accordance with the material specification and with the owner's approval.

K323.2 Temperature Limitations A00

The designer shall verify that materials which meet other requirements of this Chapter are suitable for service throughout the operating temperature range. Attention is directed to Note (4) in Appendix K, and para. K323.2.1 following. [Note (7) of Appendix A explains the means used to set both cautionary and restrictive temperature limits for materials.]

K323.2.1 Upper Temperature Limits, Listed Materials. A00 A listed material may be used at a temperature above the maximum for which a stress value is shown in Table K-1, but only if:

(a) there is no prohibition in Appendix K or elsewhere in this Chapter;

(b) the designer verifies the serviceability of the material in accordance with para. K323.2.4; and

(c) the upper temperature limit shall be less than the temperature for which an allowable stress determined in accordance with para. 302.3.2 is governed by the creep or stress rupture provisions of that paragraph.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:57 2005

A00 **K323.2.2 Lower Temperature Limits, Listed Materials**

(a) The lowest permitted service temperature for a component or weld shall be the impact test temperature determined in accordance with para. K323.3.4(a), except as provided in (b) or (c) below.

(b) For a component or weld subjected to a longitudinal or circumferential stress ≤ 41 MPa (6 ksi), the lowest service temperature shall be the lower of −46°C (−50°F) or the impact test temperature determined in para. K323.3.4(a).

(c) For materials exempted from Charpy testing by Note (6) of Table K323.3.1, the service temperature shall not be lower than −46°C (−50°F).

A00 **K323.2.3 Temperature Limits, Unlisted Materials.** An unlisted material acceptable under para. K323.1.2 shall be qualified for service at all temperatures within a stated range from design minimum temperature to design (maximum) temperature, in accordance with para. K323.2.4. The requirements of para. K323.2.1(c) also apply.

K323.2.4 Verification of Serviceability

(a) When an unlisted material is used, the designer is responsible for demonstrating the validity of the allowable stresses and other design limits, and of the approach taken in using the material, including the derivation of stress data and the establishment of temperature limits.

(b) Paragraph 323.2.4(b) applies except that allowable stress values shall be determined in accordance with para. K302.3.

K323.3 Impact Testing Methods and Acceptance Criteria

K323.3.1 General. Impact testing shall be performed in accordance with Table K323.3.1 on representative samples using the testing methods described in paras. K323.3.2, K323.3.3, and K323.3.4. Acceptance criteria are described in para. K323.3.5.

K323.3.2 Procedure. Paragraph 323.3.2 applies.

K323.3.3 Test Specimens

(a) Each set of impact test specimens shall consist of three specimen bars. Impact tests shall be made using standard 10 mm (0.394 in.) square cross section Charpy V-notch specimen bars oriented in the transverse direction.

(b) Where component size and/or shape does not permit specimens as specified in (a) above, standard 10 mm square cross-section longitudinal Charpy specimens may be prepared.

(c) Where component size and/or shape does not permit specimens as specified in (a) or (b) above, subsize longitudinal Charpy specimens may be prepared. Test temperature shall be reduced in accordance with Table 323.3.4. See also Table K323.3.1, Note (6).

(d) If necessary in (a), (b), or (c) above, corners of specimens parallel to and on the side opposite the notch may be as shown in Fig. K323.3.3.

K323.3.4 Test Temperatures. For all Charpy impact tests, the test temperature criteria in (a) or (b) below shall be observed.

(a) Charpy impact tests shall be conducted at a temperature no higher than the lowest metal temperature at which a piping component or weld will be subjected to a stress greater than 41 MPa (6 ksi). In specifying the required test temperature, the following shall be considered:

(1) range of operating conditions;

(2) upset conditions;

(3) ambient temperature extremes; and

(4) required leak test temperature.

(b) Where the largest possible test specimen has a width along the notch less than the lesser of 80% of the material thickness or 8 mm (0.315 in.), the test shall be conducted at a reduced temperature in accordance with Table 323.3.4, considering the temperature as reduced below the test temperature required by (a) above.

K323.3.5 Acceptance Criteria

(a) Minimum Energy Requirements for Materials Other Than Bolting. The applicable minimum impact energy requirements for materials shall be those shown in Table K323.3.5. Lateral expansion shall be measured in accordance with ASTM A 370 (for title see para. 323.3.2). The results shall be included in the impact test report.

(b) Minimum Energy Requirements for Bolting Materials. The applicable minimum energy requirements shall be those shown in Table K323.3.5 except as provided in Table K323.3.1.

(c) Weld Impact Test Requirements. Where two base metals having different required impact energy values are joined by welding, the impact test energy requirements shall equal or exceed the requirements of the base material having the lower required impact energy.

(d) Retests

(1) Retest for Absorbed Energy Criteria. When the average value of the three specimens equals or

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:57:57 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617574 283 ■

exceeds the minimum value permitted for a single specimen, and the value for more than one specimen is below the required average value, or when the value for one specimen is below the minimum value permitted for a single specimen, a retest of three additional specimens shall be made. The value for each of these retest specimens shall equal or exceed the required average value.

(2) Retest for Erratic Test Results. When an erratic result is caused by a defective specimen or uncertainty in the test, a retest will be allowed. The report giving

TABLE K323.3.1
IMPACT TESTING REQUIREMENTS

	Test Characteristics	Column A Pipe, Tubes, and Components Made From Pipe or Tubes	Column B Other Components, Fittings, Etc.	Column C Bolts
Tests on Materials	Number of tests	As required by the material specification, or one test set per lot [see Note (1)], whichever is greater, except as permitted by Note (6).		
	Location and orientation of specimens [see Note (2)]	(a) Transverse to the longitudinal axis, with notch parallel to axis. [See Note (3).] (b) Where component size and/or shape does not permit specimens as specified in (a) above, paras. K323.3.3(b), (c), and (d) apply as needed.	(a) Transverse to the direction of maximum elongation during rolling or to direction of major working during forging. Notch shall be oriented parallel to direction of maximum elongation or major working. (b) If there is no single identifiable axis, e.g., for castings or triaxial forgings, specimens shall either meet the longitudinal values of Table K323.3.5, or three sets of orthogonal specimens shall be prepared, and the lowest impact values obtained from any set shall meet the transverse values of Table K323.3.5. (c) Where component size and/or shape does not permit specimens as specified in (a) or (b) above, paras. K323.3.3(c) and (d) apply as needed.	(a) Bolts ≤ 52 mm (2 in.) nominal size made in accordance with ASTM A 320 shall meet the impact requirements of that specification. (b) For all other bolts, longitudinal specimens shall be taken. The impact values obtained shall meet the transverse values of Table K323.3.5.
Tests on Welds in Fabrication or Assembly	Test pieces [see Note (5)]	Test pieces for preparation of impact specimens shall be made for each welder, welding procedure, type of electrode, or filler metal (i.e., AWS E-XXXX classification) and each flux to be used. All test pieces shall be subject to heat treatment, including cooling rates and aggregate time at temperature or temperatures, essentially the same as the heat treatment which the finished component will have received.		
	Number of test pieces [see Note (4)]	(1) One test piece with a thickness T for each range of material thicknesses which can vary from $\frac{1}{2}T$ to $T + 6$ mm ($\frac{1}{4}$ in.). (2) Unless otherwise specified in this Chapter [see Note (3)] or the engineering design, test pieces need not be made from individual material lots, or from material for each job, provided welds in other certified material of the same thickness ranges and to the same specification (type and grade, not heat or lot) have been tested as required and the records of those tests are made available.		
	Location and orientation of specimens	(1) Weld metal impact specimens shall be taken across the weld with the notch in the weld metal. Each specimen shall be oriented so that the notch axis is normal to the surface of the material and one face of the specimen shall be within 1.5 mm ($\frac{1}{16}$ in.) of the surface of the material. (2) Heat affected zone impact specimens shall be taken across the weld and have sufficient length to locate the notch in the heat affected zone, after etching. The notch shall be cut approximately normal to the material surface in such a manner as to include as much heat affected zone material as possible in the resulting fracture. (3) The impact values obtained from both the weld metal and heat affected zone specimens shall be compared to the transverse values in Table K323.3.5 for the determination of acceptance criteria.		

Notes to this Table follow on next page

TABLE K323.3.1 (CONT'D)

NOTES:

(1) A lot shall consist of pipe or components of the same nominal size, made from the same heat of material, and heat treated together. If a continuous type furnace is used, pipe or components may be considered to have been heat treated together if they are processed during a single continuous time period at the same furnace conditions.

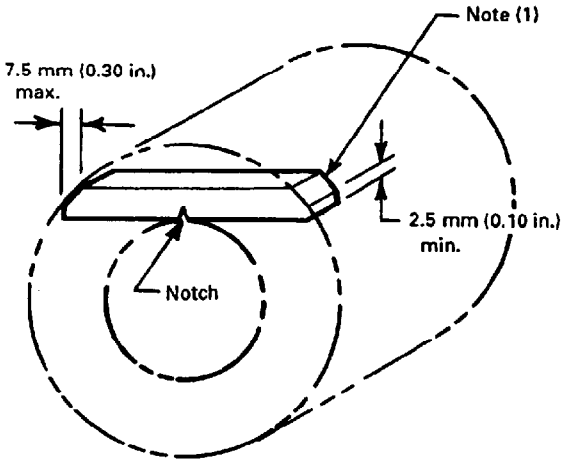
(2) Impact tests shall be performed on a representative sample of material after completion of all heat treatment and forming operations involving plastic deformation, except that cold bends made in accordance with para. K304.2.1 need not be tested after bending.

(3) For longitudinally welded pipe, specimens shall be taken from the base metal, weld metal, and the heat affected zone.

(4) The test piece shall be large enough to permit preparing the number of specimens required by para. K323.3. If this is not possible, additional test pieces shall be prepared.

(5) For welds in the fabrication or assembly of piping or components, including repair welds.

(6) Impact tests are not required when the maximum obtainable longitudinal Charpy specimen has a width along the notch less than 2.5 mm (0.098 in.). See para. K323.2.2(c).



GENERAL NOTE: This Figure illustrates how an acceptable transverse Charpy specimen can be obtained from a tubing or component shape too small for a full length standard specimen in accordance with ASTM A 370. The corners of a longitudinal specimen parallel to and on the side opposite the notch may be as shown.

NOTE:

(1) Corners of the Charpy specimen [see para. K323.3.3(d)] may follow the contour of the component within the dimension limits shown.

FIG. K323.3.3 EXAMPLE OF AN ACCEPTABLE IMPACT TEST SPECIMEN

test results shall specifically state why the original specimen was considered defective or which step of the test procedure was carried out incorrectly.

K323.4 Requirements for Materials

K323.4.1 General. Requirements in para. K323.4 apply to pressure-containing parts, not to materials used as supports, gaskets, packing, or bolting. See also Appendix F, para. F323.4.

K323.4.2 Specific Requirements

(a) Ductile iron and other cast irons are not permitted.

(b) Zinc-coated materials are not permitted for pressure containing components and may not be attached to pressure-containing components by welding.

TABLE K323.3.5
MINIMUM REQUIRED CHARPY V-NOTCH IMPACT VALUES

Specimen Orientation	Pipe Wall or Component Thickness, mm (in.)	No. of Specimens [Note (1)]	Energy, J (ft-lbf) [Note (2)] Specified Minimum Yield Strength, MPa (ksi) ≤ 932 (≤ 135)	> 932 (> 135)
Transverse	≤ 25 (≤ 1)	Average for 3	27 (20)	34 (25)
		Minimum for 1	20 (15)	27 (20)
	> 25 and ≤ 51 (> 1 and ≤ 2)	Average for 3	34 (25)	41 (30)
		Minimum for 1	27 (20)	33 (24)
	> 51 (> 2)	Average for 3	41 (30)	47 (35)
		Minimum for 1	33 (24)	38 (28)
Longitudinal	≤ 25 (≤ 1)	Average for 3	54 (40)	68 (50)
		Minimum for 1	41 (30)	54 (40)
	> 25 and ≤ 51 (> 1 and ≤ 2)	Average for 3	68 (50)	81 (60)
		Minimum for 1	54 (40)	65 (48)
	> 51 (> 2)	Average for 3	81 (60)	95 (70)
		Minimum for 1	65 (48)	76 (56)

NOTES:
(1) See para. K323.3.5(c) for permissible retests.
(2) Energy values in this Table are for standard size specimens. For subsize specimens, these values shall be multiplied by the ratio of the actual specimen width to that of a full-size specimen, 10 mm (0.394 in.).

K323.4.3 Metallic Clad and Lined Materials. Materials with metallic cladding or lining may be used in accordance with the following provisions.

(a) For metallic clad or lined piping components, the base metal shall be an acceptable material as defined in para. K323, and the thickness used in pressure design in accordance with para. K304 shall not include the thickness of the cladding or lining. The allowable stress used shall be that for the base metal at the design temperature. For such components, the cladding or lining may be any material that, in the judgment of the user, is suitable for the intended service and for the method of manufacture and assembly of the piping component.

(b) Fabrication by welding of clad or lined piping components and the inspection and testing of such components shall be done in accordance with applicable provisions of the BPV Code, Section VIII, Division 1, UCL-30 through UCL-52, and the provisions of this Chapter.

(c) If a metallic liner also serves as a gasket or as part of the flange facing, the requirements and limitations in para. K308.4 apply.

K323.5 Deterioration of Materials in Service

Paragraph 323.5 applies.

K325 MISCELLANEOUS MATERIALS

Paragraph 325 applies.

PART 8
STANDARDS FOR PIPING COMPONENTS

K326 DIMENSIONS AND RATINGS OF COMPONENTS (99) A00

Paragraph 326 applies in its entirety, except as follows:

(a) Refer to Table K326.1 instead of Table 326.1.
(b) Refer to Appendix K instead of Appendix A.
(c) Refer to para. K303 instead of para. 303.
(d) Refer to para. K304 instead of para. 304.

NOTES:
(1) It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.
(2) The use of components made in accordance with these standards is permissible provided they meet all of the requirements of this Chapter.
(3) An asterisk (*) preceding the designation indicates that the standard has been approved as an American National Standard by the American National Standards Institute.

PART 9
FABRICATION, ASSEMBLY, AND ERECTION

K327 GENERAL

Piping materials and components are prepared for assembly and erection by one or more of the fabrication processes covered in paras. K328, K330, K331, K332, and K333. When any of these processes is used in assembly or erection, requirements are the same as for fabrication.

K328 WELDING

Welding which conforms to the requirements of para. K328 may be used in accordance with para. K311.

K328.1 Welding Responsibility

Each employer is responsible for the welding done by the personnel of his organization and shall conduct the tests required to qualify welding procedures, and to qualify and as necessary requalify welders and welding operators.

Copyright by the American Society Of Mechanical Engineers

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617579 865 ■

K328.2 Welding Qualifications

K328.2.1 Qualification Requirements. Qualification of the welding procedures to be used and of the performance of welders and welding operators shall comply with the requirements of the BPV Code, Section IX, except as modified herein.

(a) Impact tests shall be performed for all procedure and performance qualifications in accordance with para. K323.3.

(b) Test weldments shall be made using the same specification and type or grade of base metal(s), and the same specification and classification of filler metal(s) as will be used in production welding.

(c) Test weldments shall be subjected to essentially the same heat treatment, including cooling rate and cumulative time at temperature, as the production welds.

(d) When tensile specimens are required by Section IX, the yield strength shall also be determined, using the method required for the base metal. The yield strength of each test specimen shall be not less than the specified minimum yield strength (SMYS) for the base metals joined. Where two base metals having different SMYS values are joined by welding, the yield strength of each test specimen shall be not less than the lower of the two SMYS values.

(e) Mechanical testing is required for all performance qualification tests.

(f) Qualification on pipe or tubing shall also qualify for plate, but qualification on plate does not qualify for pipe or tubing.

(g) For thickness greater than 51 mm (2 in.), the procedure test coupon shall be at least 75% as thick as the thickest joint to be welded in production.

(h) Paragraph 328.2.1(f) applies.

K328.2.2 Procedure Qualification by Others. Qualification of welding procedures by others is not permitted.

K328.2.3 Performance Qualification by Others. Welding performance qualification by others is not permitted.

K328.2.4 Qualification Records. Paragraph 328.2.4 applies.

K328.2.5 Performance Requalification. Requalification of welders and welding operators is required in accordance with para. K328.2.1 when:

(a) welder or welding operator has not used the specific process for a period of 3 months or more; or

(b) there is specific reason to question the individual's ability to produce welds that meet the requirements of this Chapter.

K328.3 Materials

K328.3.1 Filler Metal. Filler metal shall be specified in the engineering design and shall conform to the requirements of the BPV Code, Section IX. A filler metal not yet incorporated in Section IX may be used with the owner's approval if a procedure qualification test, including an all-weld-metal test, is first successfully made.

K328.3.2 Weld Backing Material. Backing rings shall not be used.

K328.3.3 Consumable Inserts. Paragraph 328.3.3 applies, except that procedures shall be qualified as required by para. K328.2.

K328.4 Preparation for Welding

K328.4.1 Cleaning. Paragraph 328.4.1 applies.

K328.4.2 End Preparation

(a) General

(1) Butt weld end preparation is acceptable only if the surface is machined or ground to bright metal.

(2) Butt welding end preparation contained in ASME B16.25 or any other end preparation which meets the procedure qualification is acceptable. [For convenience, the basic bevel angles taken from B16.25, with some additional J-bevel angles, are shown in Fig. 328.4.2 sketches (a) and (b).]

(b) Circumferential Welds

(1) If components ends are trimmed as shown in Fig. 328.4.2 sketch (a) or (b) to accommodate consumable inserts, or as shown in Fig. K328.4.3 to correct internal misalignment, such trimming shall not result in a finished wall thickness before welding less than the required minimum wall thickness t_m.

(2) It is permissible to size pipe ends of the same nominal size to improve alignment, if wall thickness requirements are maintained.

(3) Where necessary, weld metal may be deposited on the inside or outside of the component to permit alignment or provide for machining to ensure satisfactory seating of inserts.

(4) When a butt weld joins sections of unequal wall thickness and the thicker wall is more than $1\frac{1}{2}$ times the thickness of the other, end preparation and geometry shall be in accordance with acceptable designs for unequal wall thickness in ASME B16.5.

NOTES FOR APPENDIX A TABLES

GENERAL NOTES:

(a) The allowable stress values, P-Number or S-Number assignments, weld joint and casting quality factors, and minimum temperatures in Tables A-1, A-1A, A-1B and A-2, together with the referenced Notes and single or double bars in the stress Tables, are requirements of this Code.

(b) Notes (1) through (7) are referenced in Table headings and in headings for material type and product form; Notes (8) and following are referenced in the Notes column for specific materials. Notes marked with an asterisk (*) restate requirements found in the text of the Code.

(c) At this time, metric equivalents have not been provided in Appendix A Tables. To convert stress values in Table A-1 to MPa at a given temperature in °C, determine the equivalent temperature in °F and interpolate to calculate the stress value in ksi at the given temperature. Multiply that value by 6.895 to determine basic allowable stress S in MPa at the given temperature.

NOTES:

(1) *The stress values in Table A-1 and the design stress values in Table A-2 are basic allowable stresses in tension in accordance with para. 302.3.1(a). For pressure design, the stress values from Table A-1 are multiplied by the appropriate quality factor E (E_c from Table A-1A or E_j from Table A-1B). Stress values in shear and bearing are stated in para. 302.3.1(b); those in compression in para. 302.3.1(c).

(2) *The quality factors for castings E_c in Table A-1A are basic factors in accordance with para. 302.3.3(b). The quality factors for longitudinal weld joints E_j in Table A-1B are basic factors in accordance with para. 302.3.4(a). See paras. 302.3.3(c) and 302.3.4(b) for enhancement of quality factors. See also para. 302.3.1(a), footnote 1.

(3) The stress values for austenitic stainless steels in these Tables may not be applicable if the material has been given a final heat treatment other than that required by the material specification or by reference to Note (30) or (31).

(4) *Stress values printed in *italics* exceed two-thirds of the expected yield strength at temperature. Stress values in **boldface** are equal to 90% of expected yield strength at temperature. See paras. 302.3.2(d)(3) and (e).

(5) *See para. 328.2.1(f) for description of P-Number and S-Number groupings. P-Numbers are indicated by number or by a number followed by a letter (e.g., 8, or 5B, or 11A). S-Numbers are preceded by an S (e.g., S-1).

A00 (6) *The minimum temperature shown is that design minimum temperature for which the material is normally suitable without impact testing other than that required by the material specification. However, the use of a material at a design minimum temperature below −29°C (−20°F) is established by rules elsewhere in this Code, including para. 323.2.2(a) and other impact test requirements. For carbon steels with a letter designation in the Min. Temp. column, see para. 323.2.2(b) and the applicable curve and Notes in Fig. 323.2.2A.

(7) *A single bar (|) adjacent to a stress value indicates that use of the material above (if the bar is to the right) or (if the bar is to the left) below the corresponding temperature is affected as described in a referenced Note. A single bar adjacent to the "Min. Temp." value has the same significance. A double bar (‖) adjacent to a stress value indicates that use of a material is prohibited above the corresponding temperature or above some lower temperature, depending on location (as described above) and on the referenced Note. A double bar to the left of "Min. Temp." indicates prohibition below that temperature. Where no stress values are listed, a material may be used in accordance with para. 323.2 unless prohibited by a double bar.

(8) *There are restrictions on the use of this material in the text of the Code as follows.
- (a) See para. 305.2.1; temperature limits are −29°C to 186°C (−20°F to 366°F).
- (b) See para. 305.2.2; pipe shall be safeguarded when used outside the temperature limits in Note (8a).
- (c) See Table 323.2.2, Section B-2.
- (d) See para. 323.4.2(a).
- (e) See para. 323.4.2(b).
- (f) See para. 309.2.1.
- (g) See para. 309.2.2.

(9) *For pressure-temperature ratings of components made in accordance with standards listed in Table 326.1, see para. 326.2.1. Stress values in Table A-1 may be used to calculate ratings for unlisted components, and special ratings for listed components, as permitted by para. 303.

(9a) Component standards listed in Table 326.1 impose the following restrictions on this material when used as a forging: composition, properties, heat treatment, and grain size shall conform to this specification: manufacturing procedures, tolerances, tests, certification, and markings shall be in accordance with ASTM B 564.

(10) *This casting quality factor is applicable only when proper supplementary examination has been performed (see para. 302.3.3).

(11) *For use under this Code, radiography shall be performed after heat treatment.

(12) *Certain forms of this material, as stated in Table 323.2.2, must be impact tested to qualify for service below −29°C (−20°F). Alternatively, if provisions for impact testing are included in the material specification as supplementary requirements and are invoked, the material may be used down to the temperature at which the test was conducted in accordance with the specification.

(13) Properties of this material vary with thickness or size. Stress values are based on minimum properties for the thickness listed.

(14) For use in Code piping at the stated stress values, the required minimum tensile and yield properties must be verified by tensile test. If such tests are not required by the material specification, they shall be specified in the purchase order.

(15) These stress values are established from a consideration of strength only and will be satisfactory for average service. For bolted joints where freedom from leakage over a long period of time without retightening is required, lower stress values may be necessary as determined from the flexibility of the flange and bolts and corresponding relaxation properties.

(16) An E_j factor of 1.00 may be applied only if all welds, including welds in the base material, have passed 100% radiographic examination. Substitution of ultrasonic examination for radiography is not permitted for the purpose of obtaining an E_j of 1.00.

(17) Filler metal shall not be used in the manufacture of this pipe or tube.

(18) *This specification does not include requirements for 100% radiographic inspection. If this higher joint factor is to be used, the material shall be purchased to the special requirements of Table 341.3.2 for longitudinal butt welds with 100% radiography in accordance with Table 302.3.4.

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:58:00 2005

(19) *This specification includes requirements for random radiographic inspection for mill quality control. If the 0.90 joint factor is to be used, the welds shall meet the requirements of Table 341.3.2 for longitudinal butt welds with spot radiography in accordance with Table 302.3.4. This shall be a matter of special agreement between purchaser and manufacturer.

(20) For pipe sizes ≥ DN 200 (NPS 8) with wall thicknesses ≥ Sch 140, the specified minimum tensile strength is 483 MPa (70 ksi).

(21) For material thickness > 127 mm (5 in.), the specified minimum tensile strength is 483 MPa (70 ksi).

(21a) For material thickness > 127 mm (5 in.), the specified minimum tensile strength is 448 MPa (65 ksi).

(22) The minimum tensile strength for weld (qualification) and stress values shown shall be multiplied by 0.90 for pipe having an outside diameter less than 51 mm (2 in.) and a D/t value less than 15. This requirement may be waived if it can be shown that the welding procedure to be used will consistently produce welds that meet the listed minimum tensile strength of 165 MPa (24 ksi).

(23) Light-weight aluminum alloy welded fittings conforming to dimensions in MSS SP-43 shall have full penetration welds.

(24) Yield strength is not stated in the material specification. The value shown is based on yield strengths of materials with similar characteristics.

(25) This steel may develop embrittlement after service at approximately 316°C (600°F) and higher temperature.

(26) This unstabilized grade of stainless steel increasingly tends to precipitate intergranular carbides as the carbon content increases above 0.03%. See also para. F323.4(c)(2).

(27) For temperatures above 427°C (800 °F), these stress values apply only when the carbon content is 0.04% or higher.

(28) For temperatures above 538°C (1000°F), these stress values apply only when the carbon content is 0.04% or higher.

(29) The stress values above 538°C (1000°F) listed here shall be used only when the steel's austenitic micrograin size, as defined in ASTM E 112, is No. 6 or less (coarser grain). Otherwise, the lower stress values listed for the same material, specification, and grade shall be used.

(30) For temperatures above 538°C (1000°F), these stress values may be used only if the material has been heat treated at a temperature of 1093°C (2000°F) minimum.

(31) For temperatures above 538°C (1000°F), these stress values may be used only if the material has been heat treated by heating to a minimum temperature of 1038°C (1900°F) and quenching in water or rapidly cooling by other means.

(32) Stress values shown are for the lowest strength base material permitted by the specification to be used in the manufacture of this grade of fitting. If a higher strength base material is used, the higher stress values for that material may be used in design.

(33) For welded construction with work hardened grades, use the stress values for annealed material; for welded construction with precipitation hardened grades, use the special stress values for welded construction given in the Tables.

(34) If material is welded, brazed, or soldered, the allowable stress values for the annealed condition shall be used.

(35) This steel is intended for use at high temperatures; it may have low ductility and/or low impact properties at room temperature, however, after being used above the temperature indicated by the single bar (|). See also para. F323.4(c)(4).

(36) The specification permits this material to be furnished without solution heat treatment or with other than a solution heat treatment. When the material has not been solution heat treated, the minimum temperature shall be −29°C (−20°F) unless the material is impact tested per para. 323.3.

(37) Impact requirements for seamless fittings shall be governed by those listed in this Table for the particular base material specification in the grades permitted (A 312, A 240, and A 182). When A 276 materials are used in the manufacture of these fittings, the Notes, minimum temperatures, and allowable stresses for comparable grades of A 240 materials shall apply.

Note (38) Deleted A00

(39) This material when used below −29°C (−20°F) shall be impact tested if the carbon content is above 0.10%.

(40) *This casting quality factor can be enhanced by supplementary examination in accordance with para. 302.3.3(c) and Table 302.3.3C. The higher factor from Table 302.3.3C may be substituted for this factor in pressure design equations.

(41) Design stresses for the cold drawn temper are based on hot rolled properties until required data on cold drawn are submitted.

(42) This is a product specification. No design stresses are necessary. Limitations on metal temperature for materials covered by this specification are: A00

Grade(s)	Metal Temperature, °C (°F)
1	−29 to 482 (−20 to 900)
2, 2H, and 2HM	−48 to 593 (−55 to 1100)
3	−29 to 593 (−20 to 1100)
4 [see Note (42a)]	−101 to 593 (−150 to 1100)
6	−29 to 427 (−20 to 800)
7 and 7M [see Note (42a)]	−101 to 593 (−150 to 1100)
8FA [see Note (39)]	−29 to 427 (−20 to 800)
8MA and 8TA	−198 to 816 (−325 to 1500)
8, 8A, and 8CA	−254 to 816 (−425 to 1500)

(42a) When used below −46°C (−50°F), this material shall be impact tested as required by A 320 for Grade L7.

(42b) This is a product specification. No design stresses are necessary. For limitations on usage, see paras. 309.2.1 and 309.2.2.

(43) *The stress values given for this material are not applicable when either welding or thermal cutting is employed [see para. 323.4.2(c)].

(44) This material shall not be welded.

(45) Stress values shown are applicable for "die" forgings only.

(46) The letter "a" indicates alloys which are not recommended for welding and which, if welded, must be individually qualified. The letter "b" indicates copper base alloys which must be individually qualified.

(47) If no welding is employed in fabrication of piping from these materials, the stress values may be increased to 230 MPa (33.3 ksi).

(48) The stress value to be used for this gray cast iron material at its upper temperature limit of 232°C (450°F) is the same as that shown in the 204°C (400°F) column.

(49) If the chemical composition of this Grade is such as to render it hardenable, qualification under P-No. 6 is required.

(50) This material is grouped in P-No. 7 because its hardenability is low.

(51) This material may require special consideration for welding qualification. See the BPV Code, Section IX, QW/QB-422. For use in this Code, a qualified WPS is required for each strength level of material.

(52) Copper-silicon alloys are not always suitable when exposed to certain media and high temperature, particularly above 100°C (212°F). The user should satisfy himself that the alloy selected is satisfactory for the service for which it is to be used.

(53) Stress relief heat treatment is required for service above 232°C (450°F).

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:58:01 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617585 069 ■

(54) The maximum operating temperature is arbitrarily set at 260°C (500°F) because hard temper adversely affects design stress in the creep rupture temperature ranges.

(55) Pipe produced to this specification is not intended for high temperature service. The stress values apply to either nonexpanded or cold expanded material in the as-rolled, normalized, or normalized and tempered condition.

(56) Because of thermal instability, this material is not recommended for service above 427°C (800°F).

(57) Conversion of carbides to graphite may occur after prolonged exposure to temperatures over 427°C (800°F). See para. F323.4(b)(2).

(58) Conversion of carbides to graphite may occur after prolonged exposure to temperatures over 468°C (875°F). See para. F323.4(b)(3).

(59) For temperatures above 482°C (900°F), consider the advantages of killed steel. See para. F323.4(b)(4).

(60) For all design temperatures, the maximum hardness shall be Rockwell C35 immediately under the thread roots. The hardness shall be taken on a flat area at least 3 mm ($\frac{1}{8}$ in.) across, prepared by removing threads. No more material than necessary shall be removed to prepare the area. Hardness determination shall be made at the same frequency as tensile tests.

(61) Annealed at approximately 982°C (1800°F).

(62) Annealed at approximately 1121°C (2050°F).

(63) For stress relieved tempers (T351, T3510, T3511, T451, T4510, T4511, T651, T6510, T6511), stress values for material in the listed temper shall be used.

(64) The minimum tensile strength of the reduced section tensile specimen in accordance with the BPV Code, Section IX, QW-462.1, shall not be less than 758 MPa (110.0 ksi).

(65) The minimum temperature shown is for the heaviest wall permissible by the specification. The minimum temperature for lighter walls shall be as shown in the following tabulation:

Impact Test Temp. (°C) for Plate Thicknesses Shown

Spec. No. & Grade	25 mm Max.	51 mm Max.	Over 51 to 76 mm
A 203 A	−68	−68	−59
A 203 B	−68	−68	−59
A 203 D	−101	−101	−87
A 203 E	−101	−101	−87

Impact Test Temp. (°F) for Plate Thicknesses Shown

Spec. No. & Grade	1 in. Max.	2 in. Max.	Over 2 in. to 3 in.
A 203 A	−90	−90	−75
A 203 B	−90	−90	−75
A 203 D	−150	−150	−125
A 203 E	−150	−150	−125

(66) Stress values shown are 90% of those for the corresponding core material.

(67) For use under this Code, the heat treatment requirements for pipe manufactured to A 671, A 672, and A 691 shall be as required by para. 331 for the particular material being used. **A00**

(68) The tension test specimen from plate 12.7 mm ($\frac{1}{2}$ in.) and thicker is machined from the core and does not include the cladding alloy; therefore, the stress values listed are those for materials less than 12.7 mm.

(69) This material may be used only in nonpressure applications.

(70) Alloy 625 (UNS N06625) in the annealed condition is subject to severe loss of impact strength at room temperature after exposure in the range of 538°C to 760°C (1000°F to 1400°F).

(71) These materials are normally microalloyed with Cb, V, and/or Ti. Supplemental specifications agreed to by manufacturer and purchaser commonly establish chemistry more restrictive than the base specification, as well as plate rolling specifications and requirements for weldability (i.e., C-equivalent) and toughness.

(72) For service temperature > 454°C (850°F), weld metal shall have a carbon content > 0.05%.

(73) Heat treatment is required after welding for all products of zirconium Grade R60705. See Table 331.1.1.

(74) Mechanical properties of fittings made from forging stock shall meet the requirements of one of the bar, forging, or rod specifications listed in Table 1 of B 366.

(75) Stress values shown are for materials in the normalized and tempered condition, or when the heat treatment is unknown. If material is annealed, use the following values above 510°C (950°F):

Temp., °F	1000	1050	1100	1150	1200
S, ksi	8.0	5.7	3.8	2.4	1.4

(76) Hydrostatic testing is an option (not required) in this specification. For use under this Code, hydrostatic testing is required.

(77) The pipe grades listed below, produced in accordance with CSA (Canadian Standards Association) Z245.1, shall be considered as equivalents to API 5L and treated as listed materials. **(99) A00**

Symbols in Temper Column

025 = hot-rolled, annealed
050 = light annealed
060 = soft annealed
061 = annealed
W050 = welded, annealed
W061 = welded, fully finished, annealed
H = drawn
H55 = light drawn
H58 = drawn, general purpose
H80 = hard drawn

TABLE A-1B (CONT'D)
BASIC QUALITY FACTORS FOR LONGITUDINAL WELD JOINTS IN PIPES, TUBES, AND FITTINGS E_j

These quality factors are determined in accordance with para. 302.3.4(a). See also para. 302.3.4(b) and Table 302.3.4 for increased quality factors applicable in special cases. Specifications, except API, are ASTM.

Spec. No.	Class (or Type)	Description	E_j (2)	Appendix A Notes

SPECIFICATION INDEX FOR APPENDIX B

Spec. No.	Title [Note (1)]
ASTM	
C 361	Reinforced Concrete Low-Head Pressure Pipe
C 582	Contact-Molded Reinforced Thermosetting Plastic (RTP) Laminates for Corrosion Resistant Equipment
C 599	Process Glass Pipe and Fittings
D 1785	PVC Plastic Pipe, Schedules, 40, 80 AND 120
D 2104	PE Plastic Pipe, Schedule 40
D 2239	PE PlasticPipe (SIDR-PR) Based on Controlled Inside Diameter
D 2241	PVC Plastic Pressure-Rated Pipe (SDR Series)
D 2447	PE Plastic Pipe, Schedules 40 and 80, Based on Outside Diameter
D 2513	Thermoplastic Gas Pressure Pipe, Tubing and Fittings
D 2517	Reinforced Epoxy Resin Gas Pressure Pipe and Fittings
D 2662	PB Plastic Pipe (SDR-PR)
D 2666	PB Plastic Tubing
D 2672	Bell-End PVC Pipe
D 2737	PE Plastic Tubing
D 2846	CPVC Plastic Hot- and Cold-Water Distribution Systems
D 2996	Filament-Wound Fiberglass RTR Pipe [Note (2)]
D 2997	Centrifugally Cast RIR Pipe
D 3000	PB Plastic Pipe (SDR-PR), Based on Outside Diameter
D 3035	PE Plastic Pipe (SDR-PR), Based on Controlled Outside Diameter
D 3309	PB Plastic Hot-Water Distribution Systems
D 3517	Fiberglass RTR Pressure Pipe [Note (2)]
D 3754	Fiberglass RTR Sewer and Industrial Pressure Pipe [Note (2)]
F 441	CPVC Plastic Pipe
F 442	CPVC Plastic Pipe, (SDR-PR)
AWWA	
C300	Reinforced Concrete Pressure Pipe, Steel Cylinder Type, for Water and Other Liquids
C301	Prestressed Concrete Pressure, Pipe Steel Cylinder Type, for Water and Other Liquids
C302	Reinforced Concrete Pressure Pipe, Steel Non-Cylinder Type, for Water and Other Liquids
C950	Glass-Fiber-Reinforced Thermosetting-Resin Pressure Pipe

GENERAL NOTE: It is not practical to refer to a specific edition of each standard throughout the Code text. Instead, the approved edition references, along with the names and addresses of the sponsoring organizations, are shown in Appendix E.

NOTES:

(1) For names of plastics identified only by abbreviation, see para. A326.3.

(2) The term *fiberglass RTR* takes the place of the ASTM designation: "*fiberglass*" *(glass-fiber-reinforced thermosetting resin).*

APPENDIX E
REFERENCE STANDARDS[1, 2]

(99)
A00

Standards incorporated in this Code by reference, and the names and addresses of the sponsoring organizations are shown in this Appendix. It is not practical to refer to a specific edition of each standard throughout the Code text; instead, the specific edition reference dates are shown here. Subsequent issues and revisions of these referenced standards and any new standards incorporated in the Code by reference in Code Addenda will be listed (after review and acceptance by the Code Committee) in revisions of this Appendix E.

A component ordinarily is not marked to indicate the edition date of the standard to which it is manufactured. It is therefore possible that an item taken from inventory was produced in accordance with a superseded edition, or an edition not yet approved by the Code (because it is of later date than that listed and is in use). If compliance with a specific edition is a requirement of the intended service, it usually will be necessary to state the specific requirement in the purchase specification and to maintain identification of the component until it is put in service.

APPENDIX F
PRECAUTIONARY CONSIDERATIONS

F300 GENERAL

This Appendix provides guidance for the designer in the form of precautionary considerations relating to particular fluid services and piping applications. These are not Code requirements but should be taken into account as applicable in the engineering design. Further information on these subjects can be found in the literature.

A00 **F301 DESIGN CONDITIONS**

Selection of pressures, temperatures, various forces, and other conditions that may apply to the design of piping can be influenced by unusual requirements which should be considered when they occur. These include but are not limited to the following.

F301.4 Ambient Effects

Where fluids can be trapped (e.g., in double seated valves) and subjected to heating and consequent expansion, means of pressure relief should be considered to avoid excessive pressure buildup.

F301.5 Dynamic Effects

geysering: an effect that can occur in piping handling fluids at or near their boiling temperatures under conditions when rapid evolution of vapor within the piping causes rapid expulsion of liquid. In such cases a pressure surge can be generated that may be destructive to the piping. (Geysering usually is associated with vertical pipelines but may occur in inclined lines under certain conditions.)

F301.7 Thermal Expansion and Contraction Effects

bowing during cooldown: an effect that can occur, usually in horizontal piping, on introduction of a fluid at or near its boiling temperature and at a flow rate that allows stratified two-phase flow, causing largecircumferential temperature gradients and possibly unacceptable stresses at anchors, supports, guides, and within pipe walls. (Two-phase flow can also generate excessive pressure oscillations and surges that may damage the piping.)

F304 PRESSURE DESIGN

F304.7 Pressure Design of Other Metallic Components

F304.7.4 Expansion Joints. The following are specific considerations to be evaluated by the designer when specifying expansion joint requirements, in addition to the guidelines given in EJMA Standards:

(a) susceptibility to stress corrosion cracking of the materials of construction, considering specific alloy content, method of manufacture, and final heat treated condition;

(b) consideration of not only the properties of the flowing medium but also the environment external to the expansion joint and the possibility of condensation or ice formation due to the operation of the bellows at a reduced temperature;

(c) consideration of specifying a minimum bellows or ply thickness. The designer is cautioned that requiring excessive bellows thickness may reduce the fatigue life of the expansion joint and increase end reactions.

(d) accessibility of the expansion joint for maintenance and inspection;

(e) need for leak tightness criteria for mechanical seals on slip type joints;

(f) specification of installation procedures and shipping or preset bars so that the expansion joint will not be extended, compressed, or offset to compensate for improper alignment of piping, other than the intentional offset specified by the piping designer;

(g) need to request data from the expansion joint manufacturer, including:

(1) effective thrust area;

(2) lateral, axial, and rotational stiffness (spring constant);

(3) calculated design cycle life under specified design conditions;

(4) friction force in hinges, tie rods, etc.;

(5) installed length and weight;

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:58:26 2005

STD.ASME B31.3A-ENGL 2000 ■ 0759670 0617629 110 ■

(6) requirements for additional support or restraint in the piping;

(7) expansion joint elements that are designed to be uninsulated during operation;

(8) certification of pressure containing and/or restraining materials of construction;

(9) maximum test pressure;

(10) design calculations.

F307 VALVES

(a) Extended bonnet valves are recommended where necessary to establish a temperature differential between the valve stem packing and the fluid in the piping, to avoid packing leakage and external icing or other heat flux problems. The valve should be positioned to provide this temperature differential. Consideration should be given to possible packing shrinkage in low temperature fluid service.

(b) The effect of external loads on valve operability and leak tightness should be considered.

F308 FLANGES AND GASKETS

F308.2 Specific Flanges

Slip-On Flanges. The need for venting the space between the welds in double-welded slip-on flanges should be considered for fluid services (including vacuum) that require leak testing of the inner fillet weld, or when fluid handled can diffuse into the enclosed space, resulting in possible failure.

F308.4 Gaskets

(a) Gasket materials not subject to cold flow should be considered for use with raised face flanges for fluid services at elevated pressures with temperatures significantly above or below ambient.

(b) Use of full face gaskets with flat faced flanges should be considered when using gasket materials subject to cold flow for low pressure and vacuum services at moderate temperatures. When such gasket materials are used in other fluid services, the use of tongue-and-groove or other gasket-confining flange facings should be considered.

(c) The effect of flange facing finish should be considered in gasket material selection.

F309 BOLTING

F309.1 General

The use of controlled bolting procedures should be considered in high, low, and cycling temperature services, and under conditions involving vibration or fatigue, to reduce:

(a) the potential for joint leakage due to differential thermal expansion;

(b) the possibility of stress relaxation and loss of bolt tension.

F312 FLANGED JOINTS

F312.1 General

Three distinct elements of a flanged joint must act together to provide a leak-free joint: the flanges, the gasket, and the bolting. Factors that affect performance include:

(a) Selection and Design

(1) consideration of service conditions (including external loads, bending moments, and application of thermal insulation);

(2) flange rating, type, material, facing, and facing finish (see para. F308.2);

(3) gasket type, material, thickness, and design (see para. F308.4);

(4) bolt material, strength (cold and at temperature), and specifications for tightening of bolts (see para. F309.1); and

(5) design for access to the joint.

(b) Installation

(1) condition of flange mating surfaces;

(2) joint alignment and gasket placement before boltup; and

(3) implementation of specified bolting procedures.

F322 DESIGN CONSIDERATIONS FOR SPECIFIC SYSTEMS

F322.6 Pressure Relief Piping

Stop Valves in Pressure Relief Piping. If stop valves are located in pressure relief piping in accordance with para. 322.6.1(a), and if any of these stop valves are to be closed while the equipment is in operation, an authorized person should be present. The authorized person should remain in attendance at a location where

NOTES:
(1) For Code reference to this Appendix, see para. 300.3.
(2) Note that the use of these units is not required by the Code. They represent sets of consistent units (except where otherwise stated) which may be used in computations, if stress values in ksi and MPa are multiplied by 1000 for use in equations that also involve pressure in psi and kPa values.

NOTES FOR APPENDIX K TABLES

GENERAL NOTES:

(a) The allowable stress values and P-Number or S-Number assignments in Table K-1, together with the referenced Notes and double bars [see Note (7) of Notes for Appendix A Tables], are requirements of Chapter IX.

(b) Notes (1) through (7) and Notes (17) and (18) are referenced in Table headings and in headings for material type and product form; Notes (8) through (16) and (19) and (20) are referenced in the Notes column for specific materials.

(c) At this time, metric equivalents have not been provided in Table K-1. To convert stress values in Table K-1 to MPa at a given temperature in °C, determine the equivalent temperature in °F and interpolate to calculate the stress value in ksi at the given temperature. Multiply by 6.895 to determine allowable stress in MPa at the given temperature.

NOTES:

(1) The stress values in Table K-1 are allowable stresses in tension in accordance with para. K302.3.1(a). Stress values in shear and bearing are stated in para. K302.3.1(b), those in compression in para. K302.3.1(c).

(2) Samples representative of all piping components, as well as their fabrication welds, shall be impact tested in accordance with para. K323.3.

(3) Material minimum service temperature shall be in accordance with para. K323.2.2.

(4) The temperature limit for materials shall be in accordance with para. K323.2.1. A double bar (‖) after a tabled stress indicates that use of the material is prohibited above that temperature.

(5) Stress values printed in *italics* exceed two-thirds of the expected yield strength at temperature. Stress values in **boldface** are equal to 90% of yield strength at temperature. See para. K302.3.2.

(6) A product analysis of the material shall be performed. See para. K323.1.5.

(7) See para. 328.2.1(f) for a description of P-Number and S-Number groupings. P-Numbers are indicated by number or by a number followed by a letter (e.g., 8, or 5B, or 11A). S-Numbers are preceded by an S (e.g., S-1).

(8) This type or grade is permitted only in the seamless condition.

(9) If this grade is cold expanded, the most severely deformed portion of a representative sample shall be impact tested in accordance with para. K323.3.

(10) This material may require special consideration for welding qualification. See the BPV Code, Section IX, QW/QB-422. For use in this Code, a qualified WPS is required for each strength level of material.

(11) No welding is permitted on this material.

(12) Welds in components shall be of a design that permits fully interpretable radiographic examination; joint quality facter E_j shall be 1.00 per para. K302.3.4.

(13) Pipe furnished to this specification shall be supplied in the solution heat treated condition.

(14) This unstabilized grade of stainless steel increasingly tends to precipitate intergranular carbides as the carbon content increases above 0.03%. See also para. F323.4(c)(2).

(15) Stress values shown are for the lowest strength base material permitted by the specification to be used in the manufacture of this grade of fitting. If a higher strength base material is used, the higher stress values for that material may be used in design.

(16) Galvanized pipe furnished to this specification is not permitted for pressure containing service. See para. K323.4.2(b).

(17) Pipe and tubing shall be examined for longitudinal defects in accordance with Table K305.1.2.

(18) Material defects may be repaired by welding only in accordance with para. K323.1.6.

(19) For material thickness > 127 mm (5 in.), the specified minimum tensile strength is 448 MPa (65 ksi).

(20) For material thickness > 127 mm (5 in.), the specified minimum tensile strength is 483 MPa (70 ksi).

APPENDIX V
ALLOWABLE VARIATIONS IN ELEVATED TEMPERATURE SERVICE

A00 **V300 APPLICATION**

(a) This Appendix covers application of the Linear Life Fraction Rule, which provides a method for evaluating variations at elevated temperatures above design conditions where material creep properties [see para. V302(c)] control the allowable stress at the temperature of the variation. This Appendix is a Code requirement only when specified by the owner in accordance with the last sentence of para. 302.2.4(f)(1).

(b) Life Fraction analysis addresses only the gross strength of piping components; it does not consider local stress effects. It is the designer's responsibility to provide construction details suitable for elevated temperature design.

V300.1 Definitions

operating condition: any condition of pressure and temperature under which the design conditions are not exceeded

excursion: any condition under which pressure or temperature, or both, exceed the design conditions

service condition: any operating condition or excursion

duration

(a) the extent of any service condition, hours;

(b) the cumulative extent of all repetitions of a given service condition during service life, hours.

service life: the life assigned to a piping system for design purposes, hours

A00 **V301 DESIGN BASIS**

Life Fraction analysis shall be performed in accordance with one of the following design basis options selected by the owner.

(a) All service conditions in the creep range and their durations are included.

(b) To simplify the analysis, less severe service conditions need not be individually evaluated if their durations are included with the duration of a more severe service condition.

V302 CRITERIA

(a) All of the criteria in para. 302.2.4 shall be met.

(b) Only carbon steels, low and intermediate alloy steels, austenitic stainless steels, and high nickel alloys are included.

(c) Service conditions are considered only in the calculation of the usage factors in accordance with para. V303 when the allowable stress at the temperature of those conditions in Table A-1 is based on the creep criteria stated in para. 302.3.2. (99) A00

(d) Creep-fatigue interaction effects shall be considered when the number of cycles exceeds 100.

V303 PROCEDURE

The cumulative effect of all service conditions during the service life of the piping is determined by the Linear Life Fraction Rule in accordance with the following procedure.

V303.1 Calculations for Each Service Condition *i*

The following steps shall be repeated for each service condition considered.

V303.1.1 Equivalent Stress for Pressure

(a) Using Eq. (V1), compute a pressure-based equivalent stress S_{pi}:

$$S_{pi} = S_d P_i / P_{\max.} \qquad \text{(V1)}$$

where

S_{pi} = pressure-based equivalent stress, MPa (ksi)
P_i = gage pressure, kPa (psi), during service condition i
S_d = allowable stress, MPa (ksi) at design temperature, °C (°F)

[1] Footnote 1 deleted. A00

Copyright by the American Society Of Mechanical Engineers
Wed Feb 02 00:58:31 2005

$P_{max.}$ = maximum allowable gage pressure, kPa (psi), for continuous operation of pipe or component at design temperature

(b) Compute the maximum longitudinal stress S_L during service condition i, in accordance with para. 302.3.5(c).

(c) The equivalent stress S_i for use in para. V303.1.2, is the greater of the values calculated in (a) and (b) above.

A00 **V303.1.2 Effective Temperature.** From Table A-1 find the temperature corresponding to the equivalent stress S_i using linear interpolation if necessary. This temperature T_E is the effective temperature for service condition i.

A00 **V303.1.3 Larson-Miller Parameter.** Compute the LMP for the basic design life for service condition i, using Eq. (V2):

$$\left.\begin{array}{ll} \text{SI metric:} & LMP = (C + 5)(T_E + 273) \\ \text{U.S.:} & LMP = (C + 5)(T_E + 460) \end{array}\right\} \quad \text{(V2)}$$

where

T_E = effective temperature, °C (°F); see para. V303.1.2

C = 20 (carbon, low, and intermediate alloy steels)

C = 15 (austenitic stainless steel and high nickel alloys)

V303.1.4 Rupture Life. Compute the rupture life t_{ri}, hr, using Eq. (V3):

$$t_{ri} = 10^a \quad \text{(V3)}$$

where

$$\text{SI metric:} \quad a = \frac{LMP}{T_i + 273} - C$$

$$\text{U.S.:} \quad a = \frac{LMP}{T_i + 460} - C$$

and

t_{ri} = allowable rupture life, hr, associated with a given service condition i and stress S_i

T_i = actual temperature, °C (°F), during service condition i

LMP and C are as defined in para. V303.1.3

V303.2 Determine Creep-Rupture Usage Factor A00

The usage factor u is the summation of individual usage factors t_i/t_{ri} for all service conditions considered in para. V303.1. See Eq. (V4):

$$u = \sum(t_i/t_{ri}) \quad \text{(V4)}$$

where

i = as a subscript, 1 for the prevalent operating condition; i = 2, 3, etc. for each of the other service conditions considered

t_i = total duration, hr, associated with any service condition i, at pressure P_i and temperature T_i

t_{ri} = as defined in para. V303.1.4

V303.3 Evaluation

The calculated value of u indicates the nominal amount of creep-rupture life expended during the service life of the piping system. If $u \leq 1.0$, the usage factor is acceptable including excursions. If $u > 1.0$, the designer shall either increase the design conditions (selecting piping system components of a higher allowable working pressure if necessary) or reduce the number and/or severity of excursions until the usage factor is acceptable.

APPENDIX X
METALLIC BELLOWS EXPANSION JOINTS

Design requirements of Appendix X are dependent on and compatible with EJMA standards. There are no metric equivalents and no basis for introducing them at this time.

X300 GENERAL

The intent of this Appendix is to set forth design, manufacturing, and installation requirements and considerations for bellows type expansion joints, supplemented by the EJMA Standards. It is intended that applicable provisions and requirements of Chapters I through VI of this Code shall be met, except as modified herein. This Appendix does not specify design details. The detailed design of all elements of the expansion joint is the responsibility of the manufacturer. This Appendix is not applicable to expansion joints in piping designed in accordance with Chapter IX.

X301 PIPING DESIGNER RESPONSIBILITIES

The piping designer shall specify the design conditions and requirements necessary for the detailed design and manufacture of the expansion joint in accordance with para. X301.1 and the piping layout, anchors, restraints, guides, and supports required by para. X301.2.

X301.1 Expansion Joint Design Conditions

The piping designer shall specify all necessary design conditions including the following.

X301.1.1 Static Design Conditions. The design conditions shall include any possible variations of pressure or temperature, or both, above operating levels. Use of a design metal temperature other than the fluid temperature for any component of the expansion joint shall be verified by computation, using accepted heat transfer procedures, or by test or measurement on similarly designed equipment in service under equivalent operating conditions.

X301.1.2 Cyclic Design Conditions. These conditions shall include coincident pressure, temperature, imposed end displacements and thermal expansion of the expansion joint itself, for cycles during operation. Cycles due to transient conditions (startup, shutdown, and abnormal operation) shall be stated separately. (See EJMA Standards, C-4.1.5.2 on cumulative fatigue analysis, for guidance in defining cycles.)
